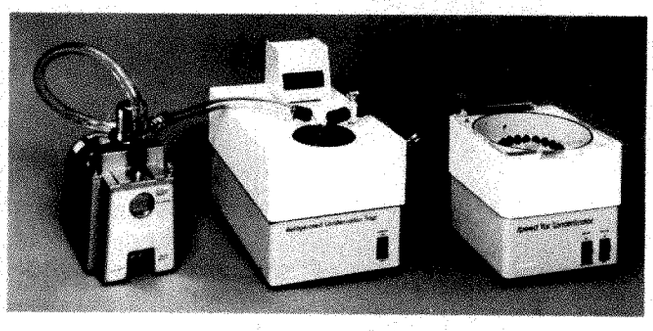
Savant's Speed Vac Evaporator Concentrator

Pat. 4226669

is a natural for Microcentrifuge Tubes.



THE SPEED VAC CONCENTRATOR is now widely used with Microcentrifuge Tubes to minimize sample loss and maximize sample concentration. A combination of rotary action and vacuum application account for the high efficiency volume reduction of the sample.

100% SAMPLE RECOVERY

NO BUMPING NO DILUTION
NO SMEARING NO TRANSFER
NO WASHDOWN NO LOSSES

The Speed Vac Concentrator has replaced Flash Evaporators, Ultrafiltration, The Bell Jar Dessicator for most applications ... e.g. Eluates, Hydrolysates, Extracts, GLC and HPLC Sample Preparation.

"No Doubt About It — This is the Preferred Method".

Savant can supply the entire system including the SPEED VAC CONCENTRATOR, the Refrigerated Trap and the Vacuum Pump, as well as many accessories which makes the laboratory completely operational.

ACADEMIC PRESS

TITLES IN AGING

MOLECULAR BASIS OF AGING

Edited by A. K. Roy and B. Chatterjee
1984, 416pp., $29.50/£24.00 (UK only), ISBN: 0.12.601060.9

Recent advances in molecular biology have led to a new understanding of the molecular basis of aging at the level of gene expression and gene organization. This volume, contributed to by noted experts in the field, presents state-of-the-art developments in this rapidly expanding area of biochemical gerontological research.

In chapters in which various aspects of the molecular basis of aging are discussed, background information is presented, followed by reviews of the results of recent investigations and the significance of these results in the development of new concepts.

The 1984 Sandoz Lectures in Gerontology

THRESHOLDS IN AGING

Edited by: Professor M. Bergener, Dr. M. Ermini, Dr. H. B. Stahelin
1985, 322pp., $25.00/£22.50 (UK only), ISBN: 0.12.090160.9

This volume provides a record of an international meeting convened in Basle, Switzerland, in February 1984, at which leading scientists presented current work on biological, neurological and epidemiological aspects of the aging process. The contributions to this book reflect the exciting, multidisiplinary approach of modern gerontology.

BIOLOGY OF MENOPAUSE

The Causes and Consequences of Ovarian Ageing

R. G. Gosden
1985, 188pp., $37.50/£29.00 (UK only), ISBN: 0.12.291850.9

All the diverse aspects of ovarian ageing in our own species and in animal models have been brought together for the first time in this concise volume. The physiological and biochemical processes responsible for the deterioration of ovarian function, the consequential loss of fertility, and somatic effects of postmenopause are fully explained for biologists interested in reproduction and gerontology and for clinicians concerned with fertility in middle age and hormone replacement therapy.

Monographs of the Physiological Society No. 42

MEMOIR ON THE PANCREAS

And on the Role of Pancreatic Juice in Digestive Processes Particularly in the Digestion of Neutral Fat

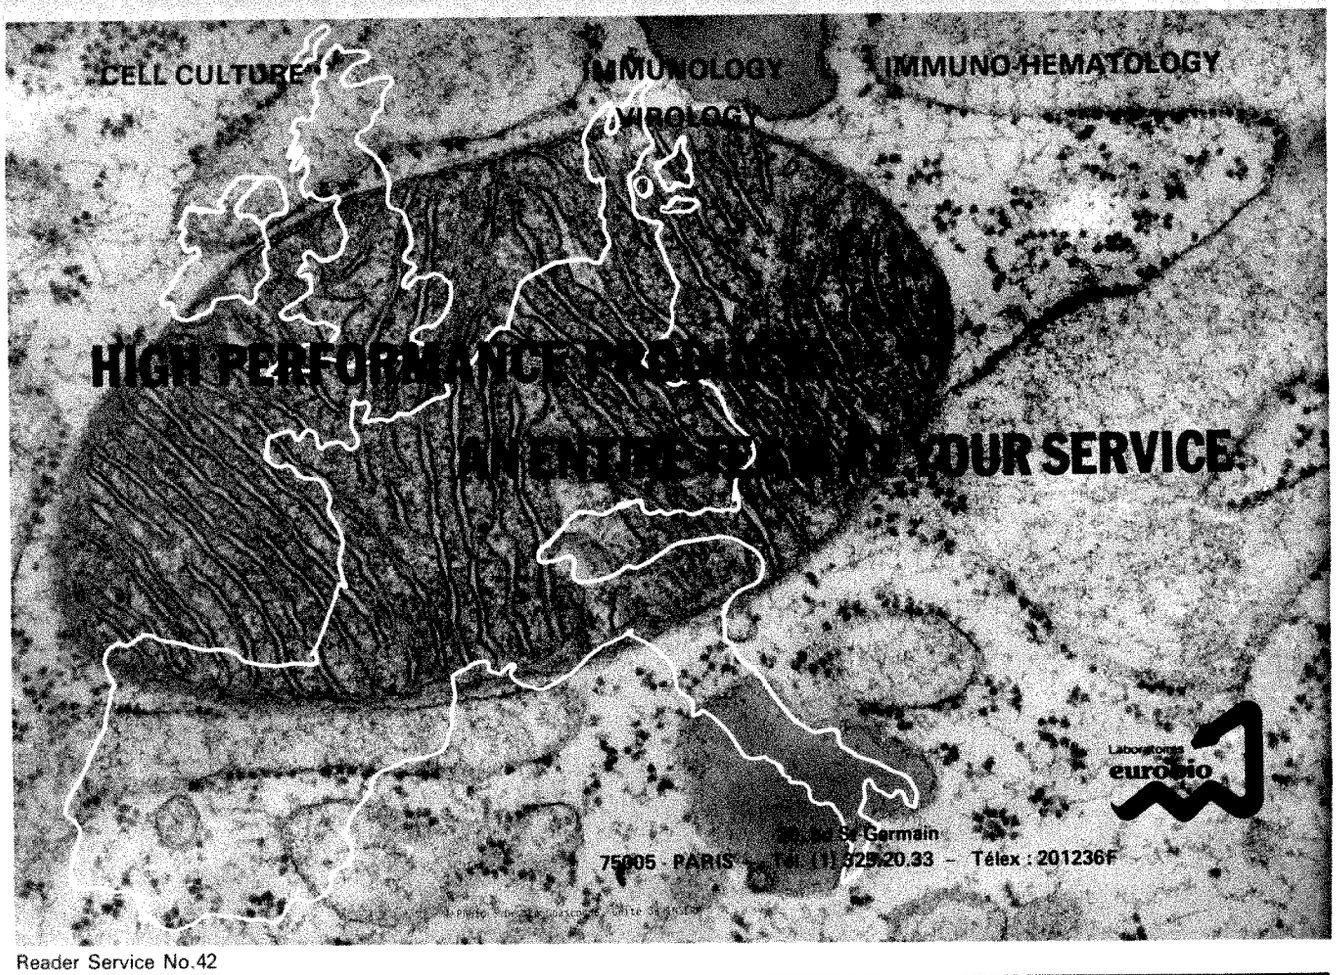
Written by C. Bernard
Translated by J. Henderson
1985, 131pp., $48.00/£36.00 (UK only), ISBN: 0.12.092880.9

This volume, the first English translation, details these studies and follows Bernard's line of hypothesis through many experiments. Claude Bernard describes the comparative anatomy of the gland (beautifully illustrated by colour and black and white engravings) and demonstrates both the collection and the chemistry of the pancreatic juice. The Memoir also includes descriptions of human pancreatic disease, and a good deal of speculation on the role of the pancreas in humans and the rest of the animal kingdom, while at the same time it criticises severely a large number of his contemporaries who disagree with him.

NOW IN STOCK

ASSESSMENT OF SKELETAL MATURITY AND PREDICTION OF ADULT HEIGHT (TW2 METHOD)

Second Edition



J. M. Tanner, R. H. Whitehouse, N. Cameron, W. A. Marshall, M. J. R. Healey and H. Goldstein
1984, 116pp., $49.50/£33.00 (UK only), ISBN: 0.12.683360.5

Accurate assessment of 'bone age' in children is essential in diagnosing and monitoring treatment of children with growth disorders. In this second edition, new data from very tall, short and delayed children have allowed revised formulae for predicting adult height from bone age whose greater accuracy renders those of the first edition obsolete. An essential tool for those working in paediatric medicine.

Tissue culture equipment

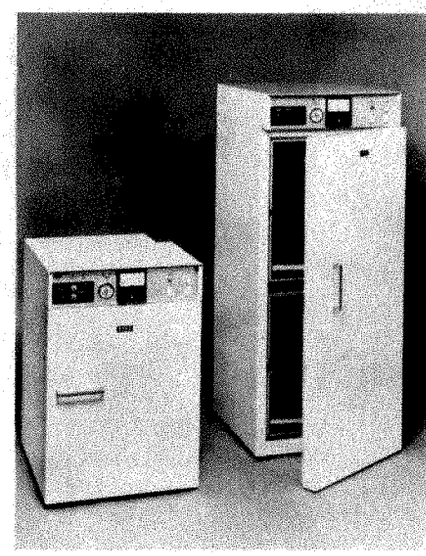
New items available for the tissue culture laboratory include carbon dioxide incubators, novel bioreactors and media.

● Imperial Laboratories of Salisbury, working with the Wessex Regional Cytogenetics Unit at Salisbury General Hospital, have developed a new medium for use in cytogenetics procedures. This medium, based on Iscove's modificaiton of Dulbecco's MEM, has the folic acid level reduced from the normal 4.00 mg to 0.01 mg per litre. The folate-deficient Iscove's medium has proved successful in producing mitotic indices, with well-spread elongated chromosomes suitable for high resolution banded analysis, and is now used routinely at the Salisbury hospital for all lymphocyte cultures and also for bone marrow specimens from patients with leukaemia.
Reader Service No. 100.

● A new cell culture medium, Ventrex PC-1, is now available from Tissue Culture Services to complement the Ventrex HL-1 medium. Like HL-1, Ventrex PC-1 is a low-protein, serum-free medium which has been specially formulated using defined components for optimal cell growth, while maintaining the lowest possible protein content (less than 750 μg per ml). The PC-1 medium is intended for the culture of primary cells and cell lines and has been successfully tested on many widely used cell lines. Ventrex PC-1 is available as a sterile liquid base medium, with a sterile frozen supplement, in 1 × 100 ml and 2 × 500 ml packs. When stored under suitable conditions, the components are stable for 120 days; when the components are combined to form the complete medium, it remains stable for 45 days at 4°C. The medium is also available in a 10-litre component package for users who prefer to prepare their own media.
Reader Service No. 101.

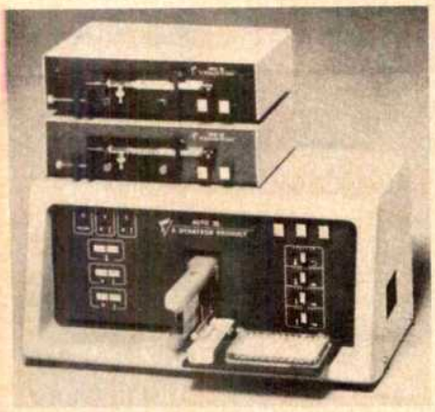
● Opti-MEM I from Gibco is a multi-use reduced serum medium which supports optimal growth with reduced fetal bovine serum for a wide variety of mammalian cells. Most cells routinely cultured in serum-supplemented medium may be directly transferred into Opti-MEM I with a minimum of 50% reduction in serum. Opti-MEM I is performance-tested for cloning efficiency and growth promotion using various mammalian cell types, including murine myelomas, hybridomas and adherent cultures. Opti-MEM I has a shelf life of six months from date of manufacture, and is easily prepared in only three steps: add 2-mercaptoethanol (included); mix thoroughly; and add fetal bovine serum.

These notes are based on information provided by the manufacturers. Use the reader service card bound inside the journal to obtain further information.



Clandon's new cell counter.

● The range of Diffcount II microprocessor-controlled differential cell counters has been extended with the introduction of Comp-U-Diff, a direct differential data entry terminal. Manufactured by Modulus Data Systems, and available in the UK from Clandon Scientific, the Diffcount II/Comp-U-Diff allows efficient, direct, computer entry of the differential counts, RBC morphology, MLSO ID code, specimen identification and general comments. Straightforward instructions and suggested software enable Comp-U-Diff to be readily interfaced with an existing laboratory computer.
Reader Service No. 103.

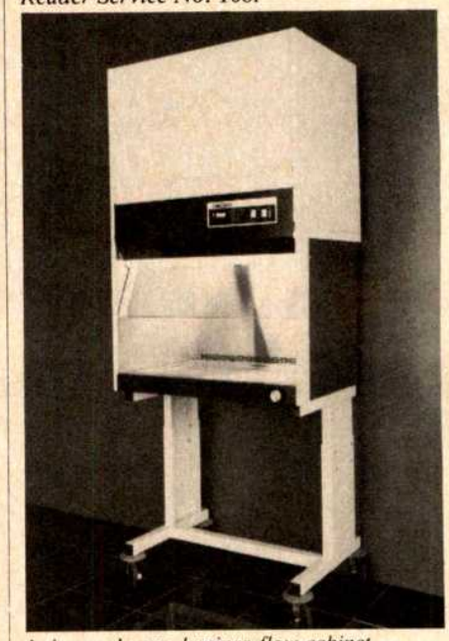


● MBR Bioreactor AG has introduced a membrane bioreactor for the cultivation of mammalian, plant, hybrid cells and microorganisms. The Membroferm consists of a medium chamber, a cell chamber and a product chamber which are fitted with a special net support which acts as a carrier to fix the cells as well as supporting the membranes. This membrane stack is held in position by stainless steel endplates which are fitted with connections to the conditioning vessel where the medium can be continuously treated to maintain the correct environment for growth of the cells. Cells are introduced into the cell chamber which is separated from the medium chamber by a membrane on one side and the product chamber with a different membrane on the other side. This allows the cells to receive nutrients and gases via the medium chamber and to remove the products of metabolism or toxins via the product chamber. The technique has achieved very high cell densities with mammalian cells.
Reader Service No. 104.

● Plant diseases can cause crop losses ranging from slight yield depression to complete crop failure. To counter this Twyford Plant Laboratories offers 'disease indexing' services to plant breeders, propagators, seed producers and growers. Using this service it is possible to 'clean-up' a plant or crop, for further use as a mother stock for further propagation, or as parent plants for high quality seed production, for instance. TPL's indexing service is based on the use of plant tissue culture. Viruses are identified by a range of techniques including ELISA, PAGE and occasionally electron microsopy. Fungal diseases are detected using selective nutrient media. For more details on TPL's range of techniques based on an expertise in plant tissue culture use the reader service card.
Reader Service No. 105.

Tissue culture incubators from LEEC.

● In the tissue culture laboratory, CO_2 incubators with high humidity levels are constantly subjected to contamination by yeasts, moulds and all forms of airborne bacteria. The new LEEC range of automatic CO_2 incubators incorporates a self-sterilizing facility which by-passes the normal heater controls and holds the temperature at 90°C. On completion of a cycle the control is transferred back to the normal controllers and the incubator rapidly re-stabilizes at pre-set temperatures. The range includes models of 150 litres and 320 litres capacity, each featuring dual proportional voltage controllers, safety overides, heated inner glass door, solid state CO_2 detection and a self-sterilizing facility. The LEEC range of incubators is manufactured with high-grade stainless steel throughout.
Reader Service No. 106.



The Dynatech Autodiluter with features aimed at tissue culture.

● Through the use of modular, solid-state logic controls, the Dynatech Autodiluter III can be programmed to carry out such diverse procedures as ELISA washing and aspirating, haemagglutination, complement fixation, microtitration and a variety of tissue culture applications. The Autodiluter III can be linked to Dynatech's Dynadrop multi-reagent dispenser, for simultaneous addition of up to 12 different reagents to a row of microtitre plate wells. Aspirator dwell time can be controlled between 2 and 6 s and the downward travel of the head limited, a feature necessary in tissue culture where the Microdiluter and aspirator tips must not touch the bottom of wells.

Reader Service No. 107.

● Dystonia is a neurologic disease consisting of sustained twisting movements and postures. It may be inherited, sporadic, or secondary to other nervous system diseases. The Dystonia Clinical Research Center at Columbia University has established a Fibroblast Tissue Resource Facility. Fibroblasts from patients with genetic and sporadic dystonia (as well as controls) are cultured and stored in liquid nitrogen; samples are available to investigators with established probes for biochemical markers. The Columbia centre invites scientists to utilize the tissue bank without charge. If interested, investigators should send a brief description of assays to be carried out to: Stanley Fahn, Director, Dystonia Clinical Research Center, Neurological Institute, 710 West 168th Street, New York, New York 10032, USA.

Reader Service No. 108.

Labconco's new laminar flow cabinet.

● Labconco's new range of laminar flow cabinets — the Purifier Class II — is well suited to tissue culture manipulations including inoculation of viruses. A stainless steel working area and coved and dished work surface contribute to operator protection. Other features include a variable speed motor, easy-to-read differential pressure gauge monitor, Hepa filters readily accessible for replacement, adjustable height and position sash for comfort, remote controlled gas fixture with recessed nozzle and safety valve, and adjustable height stand on heavy duty rubber-tyred castors. All lights are recessed and accessible from the cabinet exterior. The air movement and positioning of the filters places virtually all the cabinet under negative pressure, those areas of positive pressure are surrounded by areas of negative pressure ensuring complete containment in the event of a leakage. The Purifier meets all standards for Class II operation and is supplied with full performance certificates.

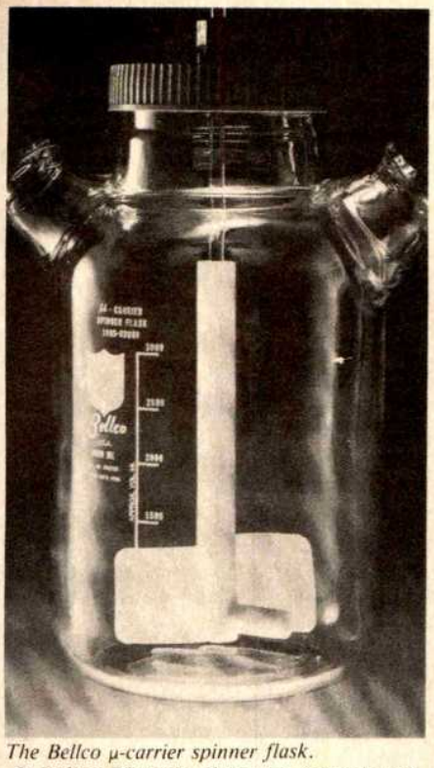
Agar...automatically from powder to plates in less than 90 minutes...

Up to 8 liters (400 plates) of high-quality agar whenever you need it

Any laboratory can have high quality agar whenever it's needed thanks to two benchtop instruments — the AgarMatic, an 8 liter sterilizer, and the PourMatic, a self-stacking carousel-type petri dish filler.

Simply add water and dehydrated medium to the AgarMatic. Then set it and forget it. This automatic sterilizer does the rest. Fresh, chemically superior agar or nutrient broth is ready to pour in less than an hour. If you're not back in time, the agar will be maintained at the desired pouring temperature.



By adding the PourMatic, agar can be sterilized, cooled, poured into plates and stacked . . . all automatically in only 38" of bench space while you tend to more important activities. Microprocessor control assures dependability and minimizes operator supervision.

Agar sterilizers from 3 to 130 liters are also available. Send for 16-page catalog. New Brunswick Scientific Co., Inc., P.O. Box 986, Edison, N.J. 08818, (201) 287-1200 or (800) 631-5417.

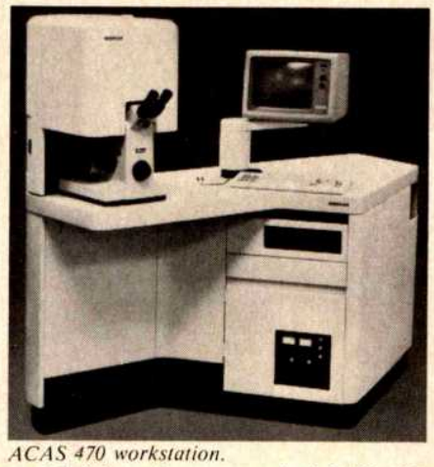
Reader Service No.49



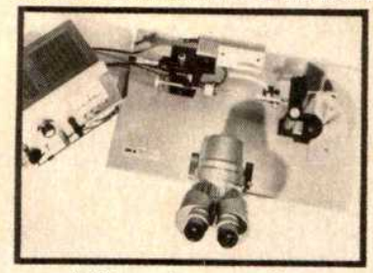
The Bellco μ-carrier spinner flask.

● Bellco Biotechnology has introduced a new line of non-heating, precision magnetic stirrers. The Sci/ERA range is offered in one-, two- and four-position units, each featuring a port to accept computer-generated commands for external control. Stirring speeds are set with a precision ten-turn control, and are ramped up and down to minimize disruption of cell attachment. Two LED displays are incorporated; one indicates stirrer r.p.m., and the other reads out cycle and countdown to show exactly where the system is in relation to internally-controlled cycles. Electronic on/off cycle timers permit precise repetitive cycling. Stepper motors are controlled by pulses generated with such precision that repeatability of settings is ±0.1 r.p.m., 12-volt signal level assures operation at selected speed if the system switches to back-up battery power. In addition, the new Bellco system offers a new stand-by Sci/ERA Power Pack to protect stirrers and valuable cell cultures in the event of failure of the main power supply.
Reader Service No. 110.

● The new 50-watt Model MS-50 Microson miniature ultrasonic cell disruptor is intended primarily for cell disruption, homogenization, and emulsification in the laboratory and classroom. The Microson, from Heat Systems-Ultrasonics, Inc., can also degas liquids, accelerate chemical and physical reactions, and deagglomerate and disaggregate. The unit features a new on/off momentary control switch, and micro cup horn for disruption in total isolation and a micro-Pulsar cycle timer for limiting temperature build up in heat-labile materials.
Reader Service No. 111.

● An eight-page brochure from Beckman describes two compact Microfuge centrifuges used for spinning down small samples fast. The Microfuge 11 and 12 provide a choice of three rotors. The Microfuge 11 has a fixed horizontal rotor; and the Microfuge 12 a bowl rotor. Both can spin the 13.2 fixed angle rotor and the capillary tube rotor.
Reader Service No. 112.

● A modification kit is now available to convert the standard Marubishi fermenter for the growth of cells in continuous culture. The modification is suited to both bacterial and cell cultivation units. All components are interchangeable and do not require additional expense or modifications when different size vessels are used. The standard bench-top fermentor is equipped with temperature, agitation and aeration controls. The transfer of medium is accomplished by pumps which automatically remove medium to be processed and add back medium from a reservoir.
Reader Service No. 113.



ACAS 470 workstation.

● Meridian Instruments' ACAS 470 workstation combines the methods of automated clonal isolation and fluorescence analysis into a single system that will (1) automatically isolate a clonal population of any cell type in monolayer culture; (2) perform selection and analyses of cells without removal from growth surfaces or altering morphology, phenotype or variability; (3) maintain the selected cell(s) under controlled growth conditions; (4) catalogue cells by location on a growth surface; (5) perform the full range of steady-state fluorescence analyses. Cell selection and separation are achieved by growing cells on specially treated cover slips in a standard tissue culture dish. The cover slips can be transferred to the environmental cell chamber to maintain selected cell(s) in a state of clonal growth. This autoclavable mini-incubator mounts on an inverted microscope. The cells are maintained at the desired temperature while sufficient nutrients are provided by a controllable continuous flow of medium across the inserted growth plate. A removable top allows convenient access to the cells for *in situ* manipulations.

LIPOSOMES NEW!
reproductive — homogeneous — extremely rapid —

The new commercial **LIPOSOMAT** provides reproducible preparation of uniformly sized unilamellar liposomes (formation within 10 minutes) with very high encapsulation efficiency for both hydrophilic and/or lipophilic agents. Liposome size selectable between 25 and 60mm in diameter. Lipid loss far below 1%.
Sample volume normally 5-10 ml or up to 200 ml if used in combination with an additional apparatus.
The LIPOSOMAT® is used especially for studying drug/potein/cell — liposome interactions in vitro and in vivo, for reconstitution experiments, and for the transfer of genetic material in gene and biotechnology.

The latest version of the Cambridge Technology cell harvester.

● A new version of Cambridge Technology's PHD Cell Harvester, the Model 290, gives the user the choice of punching and depositing the samples into scintillation vials at the time of harvesting or at some later time. This feature is particularly useful when processing a large volume of samples. It minimizes the number of scintillation vial trays needed and permits compact temporary storage of harvested samples on filter mats. Either mode of operation is selected simply by turning a knob. In the non-punching mode, small keying holes are made in the filter mat during harvesting that precisely align the mats for automatic punching and depositing later. The holes also prevent the samples from being mixed-up or reversed. The unit harvests and/or punches 24 samples in each operation. All PHD accessories and options such as special heads, supernatant collection systems, wash manifolds, and quick disconnects can be used with this new instrument.

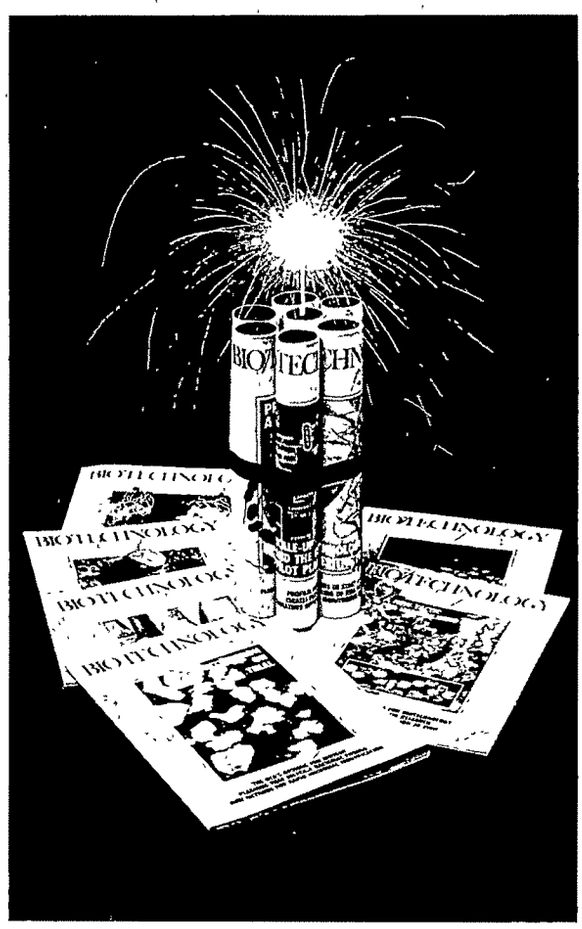
Culture tubes from Bio-Rad.

● Made without mould-release agents, Bio-Rad's 13 × 100 mm culture tubes are devoid of chemical residue to interfere with analytical results. The tubes are precision-moulded to close tolerances under conditions of extreme cleanliness. Scratched or blemished tubes are eliminated by 100% inspection. The culture tubes are not sterile, but are made of polypropylene and so may be safely autoclaved. The 13-mm stoppers fit tightly and prevent leaks. All items are packaged to eliminate dust and are kept in stock for immediate shipment.
Reader Service No. 116.

● An automatic CO_2 incubator recently introduced by VWR Scientific includes a novel new control system. The Series 1800 IR automatic CO_2 incubator is equipped with an infrared control system capable of sensing a change in concentration as small as 0.1% CO_2. Available in single-chamber and dual-chamber styles, all Series 1800 IR incubators have a readable, easy-to-set CO_2 controller. A CO_2 alarm alerts the user to high or low CO_2 concentration, extra-large water jackets ensure temperature uniformity, and an access port allows easy verification of CO_2 levels.
Reader Service No. 117.

● A new serum-free medium from Costar Biologicals has been developed primarily for culturing hybridomas and T cells. This medium, SF-1, has a total protein concentration of less than 50 $\mu g\ ml^{-1}$ and obviates the need for addition of serum completely. Antigen-specific cytotoxic and helper T-cells can be isolated and propagated in SF-1 without loss of function. The purification of antibody-containing supernatants is greatly facilitated. SF-1 is packaged in 'normal' 100 and 500ml bottles and is stable for 6 months at +4 °C. Also new from Costar Biologicals are two hybridoma growth factors capable of eliminating the requirement for feeder layers. Both ESG (Ewing sarcoma growth factor) and HECS (human endothelial culture supernatant) enhance the efficiency of fusion and subsequent cloning (up to 80%) and maximize poliferation rate.
Reader Service No. 118.



● The typing or classification of a monoclonal antibody's immunoglobulin class or subclass is best done when the antibody is in culture supernatant. Conventional methods of typing (such as traditional Ouchterlony diffusion) cannot be performed on unconcentrated supernatants, but now the new Miles monoclonal typing kits make it possible to utilize the easy-to-use Ouchterlony technique for the determination of the immunoglobin class of mouse or rat monoclonal antibodies in tissue culture supernatants. The kits allow detection of monoclonal antibodies at down to 0.1mg per dl.

CONVENIENT·INFORMATIVE·TIMELY·PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1. You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2. You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3. You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4. You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

Why this magazine and more than 1,000 others let us go over their books once a year.

Some magazines, we're sorry to say, keep their readers undercover. They steadfastly refuse to let BPA (Business Publications Audit of Circulation, Inc.) or any other independent, not-for-profit organization audit their circulation records.

On the other hand, over 1,000 publications (like this one) belong to BPA. Once a year, BPA auditors examine and verify the accuracy of our circulation records.

This audit provides the name, company, industry and job title of every reader each publication reaches. The information helps advertisers to determine if they are saying the right thing to the right people in the right place.

It also helps somebody else important: you. Because the more a publication and its advertisers know about you, the better they can provide you with articles and advertisements that meet your informational needs.

BPA. For readers it stands for meaningful information. For advertisers it stands for meaningful readers. Business Publications Audit of Circulation, Inc.

DEPARTMENT OF BIOCHEMISTRY

CHAIR OF BIOCHEMISTRY

Applications are invited from suitably qualified Biochemists for the post of Professor of Biochemistry which will carry with it in the first instance the Headship of the Department of Biochemistry & Soil Science. The appointment will be from as early a date as can be arranged. The salary will be in the professorial range (minimum £18,070).

Further particulars can be obtained from the Secretary and Registrar, UC NW, Bangor, Gwynedd, LL57 2DG.

Ten copies of the application (one from overseas applicants), together with the names and addresses of three referees, should be sent to reach the Secretary and Registrar by 1st July 1985. (6669)A

MARIE CURIE MEMORIAL FOUNDATION
Research Institute

GROUP LEADERS

As part of a planned expansion of these laboratories we invite applications for newly created scientific posts at group leader lelvel. We seek independent scientists with proven expertise in molecular and/or cellular biology to establish groups investigating fundamental aspects of malignant phenotype in human cancer.

Salaries and research expenditure are internally funded. Equipment and technical support are readily available. These posts are tenable for 5 years in the first instance (subsequent tenure will be dependent upon peer review) Salary, starting date etc are negotiable.

Send CV to Dr G Currie, Marie Curie Memorial Foundation, Research Institute, The Chart, Oxted, Surrey RH8 0TL Telephone 088388-2306/7. (6614)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

BIOPHYSICS GROUP

RESEARCH ASSISTANT IN PROTEIN CRYSTALLOGRAPHY

to be appointed for structure determination work on the industrially-important enzyme xylosse isomerase, on a project sponsored by the SERC Protein Engineering Steering Group. This is an opportunity for a trained crystallographer to gain experience in protein structure determination, and to participate in a protein engineering programme.

Applications including curriculum vitae and names of two referees should be sent to Mrs A Varsey, Biophysics Group, Blackett Laboratory, Imperial College, London SW7 2AZ. (6634)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

DEPARTMENT OF IMMUNOLOGY

POSTDOCTORAL RESEARCH FELLOW

Required for a three year position funded by The Wellcome Trust to join an existing team characterising the effects of various chemical enzyme inhibitors on the immune system with the eventual aim of modulating immune responses clinically. Applicants should have a background of the biosciences, preferably with some immunological experience.

Scientific enquiries to Dr A Johnstone (01-672 1255 ext 4756) and further particulars and application forms from the Personnel Officer, St. George's Hospital Medical School, Cranmer Terrace, Tooting, London SW17 0RE (ext 4873) Closing date 27 June 1985. (6628)A

RESEARCH CENTER DIRECTOR

Applications and nominations are invited for a Director, Center for Atmospheric and Biospheric Effects of Combustion, located in the Applied Science Division. The scope of the Center is interdisciplinary and includes four major areas: Combustion and Abatement, Atmospheric Pathways and Chemistry, Radiative Balance, and Ecosystem Pathways and Effects. The Director will coordinate the efforts of a number of scientists, including chemists, physicists, engineers, biologists, geologists, meteorologists, and energy analysts to carry out the objectives of the Center; will be responsible for obtaining research support from governmental and non-governmental organizations; will represent the Laboratory at various related national and international meetings; and will also carry out research within the Center. This position requires a Ph.D., and a record of distinguished leadership, outstanding research accomplishments and an international reputation in one or more of the above areas. Experience and background in program planning, development, implementation, administration and evaluation is required. The incumbent should also have experience in obtaining research funds and have a familiarity with organizations that provide these research funds. Salary will be negotiable. The successful candidate will be appointed a Senior Staff Scientist at the Lawrence Berkeley Laboratory.

Applications and/or nominations should be forwarded to: Lawrence Berkeley Laboratory, One Cyclotron Road, Employment Office 90-1042, Berkeley, CA 94720. Please specify Job A/3330. An Equal Opportunity Employer M/F/H. (NW1777)A

LAWRENCE BERKELEY LABORATORY

Cardiovascular Group Leader

Roche is a major multinational pharmaceutical company with a firm commitment to the research and development of novel drugs.

A senior vacancy has arisen in the recently restructured department of Biology for an innovative and enthusiastic scientist to form and lead a new group within the Cardiovascular section.

The successful candidate will play a key role in the cardiovascular research programme, reporting to the Head of Cardiovascular Biology. He/she will have a high degree of scientific autonomy, but will also be expected to interact effectively with Chemists, Biochemists and other Pharmacologists as part of a multidisciplinary approach to drug research.

Ideal qualifications for the post would be a PhD in pharmacology plus a few years experience of industrial Cardiovascular research encompassing both in vivo and in intro techniques.

Research facilities at the Hertfordshire based UK Research Division Headquarters are outstanding as are the company benefits/salary we can offer you.
To take things further, call **Mrs Ann Judge** on **Welwyn Garden City 328128** or write to her, enclosing details, at

Roche Products Ltd, PO Box 8, Welwyn Garden City, Herts. AL7 3AY.

ROCHE

(6684)A

NORTH EAST BIOTECHNOLOGY CENTRE

Applications are invited for the following posts which will be based at:

TEESSIDE POLYTECHNIC

in the Department of Chemical Engineering.

READER IN BIOTECHNOLOGY

To lead research teams and supervise research students and develop research projects in areas of interest to the NEBC. The major strengths of the Centre are in Fermentation, Microbial Physiology and Downstream Processing of biological products

Applicants should be well qualified academically in a discipline related to Biotechnology or Biochemical Engineering and will be expected to hold a PhD and have made a significant contribution to the literature relevant to the post.

Industrial experience would be preferable and membership of a professional institution an advantage

Salary: £13,095 — £16,467 per annum.

PRINCIPAL LECTURER IN BIOCHEMICAL ENGINEERING

To take responsibility for the operation and further development of the Biochemical Engineering content of courses in process engineering run jointly by the department of Chemical Engineering and the North East Biotechnology Centre.

It is expected that the successful candidate will also undertake research projects, especially in aspects of downstream process design

Applicants should be well qualified in Biochemical Engineering or a discipline of fundamental importance to this subject area They will have demonstrated a proven research record in a relevant area, an effective approach to student teaching and appropriate industrial experience Members of an appropriate professional institution would be an advantage.

Salary: £13,095 — £14,580 (work bar) — £16,467 per annum.

The salary on appointment will be no greater than £14,580 per annum

LECTURER II/SENIOR LECTURER BIOCHEMICAL ENGINEERING

A Biochemical Engineer to join a team of Biotechnologists promoting research, teaching and consultancy in the North East Biotechnology Centre The team will be expected to develop teaching and research programmes in one or more of the following areas Downstream Processing, Control of Fermentation Processes, and the Application of Microbial Physiology to Fermenter Design

Applicants should be well qualified academically in or a discipline related to Biotechnology or Biochemical Engineering; preferably with some industrial experience; membership of a professional institution would be an advantage.

Salary: £7,548 — £12,099 (efficiency bar) — £13,128 (work bar) — £14,061 per annum

An appointment will be made at Lecturer II level and the salary on appointment will be no greater than £12,099 per annum.

Closing date for applications in respect of all posts: 24 June 1985

An Equal Opportunity Employer

Application forms and further particulars from: Personnel Section, Teesside Polytechnic, Borough Road, Middlesbrough, Cleveland TS1 3BA. Tel: 0642 218121 Extension 4114 (6636)A

THE UNIVERSITY OF ALBERTA

invites applications for the

CANADIAN PACIFIC — ALBERTA AGRICULTURE CHAIR IN PLANT BIOTECHNOLOGY

The University of Alberta is seeking an established scientist to occupy the Canadian Pacific — Alberta Agriculture Chair in Plant Biotechnology. The occupant of the chair will be expected to carry out research related to the improvement of agriculture in Western Canada, to provide leadership within the area of plant biotechnology in the Faculties of Agriculture and Forestry, and Science, and to communicate actively with the agricultural sectors of industry and government. Candidates presently located outside the scientific university community will be given serious consideration, although scientific credentials will be of paramount importance.

The successful candidate will be a member of the Department of Plant Science, in the Faculty of Agriculture and Forestry. The Faculty of Agriculture and Forestry has ninety academic members housed in a modern, well-equipped research complex. In addition, within the Facilty of Science, members of the Departments of Botany, Genetics, and Microbiology are currently involved in basic and applied plant research The University of Alberta (approximately 25,000 students) is located in the capital city of Alberta **Please send curriculum vitae, names and addresses of at least three referees, and an outline of research interests, including reprints of relevant publications, to.**

Dr. Mary Spencer
Department of Plant Science
Faculty of Agriculture and Forestry
University of Alberta
Edmonton, Alberta T6G 2P5
Canada

Closing date for receipt of applications is August 31, 1985. Salary will be by negotiation. Appointment will commence on January 1, 1986, or as soon as possible thereafter

The University of Alberta is an equal opportunity employer but, in accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada. (NW1794)A

KAROLINSKA INSTITUTE, STOCKHOLM, SWEDEN

Invites applications for a position as

FULL PROFESSOR IN MOLECULAR BIOLOGY

The Karolinska Institute is seeking an outstanding Molecular Biologist to join the newly formed Biotechnology Center located at Huddinge University Hospital in Stockholm The successful candidate is expected to develop a vigorous independent research program. He will be expected to interact with other research teams within the center and in other departments as Karolinska Institute working in related fields. Funding for 3 Post-Doctoral positions, 3 graduate students, 1 Secretary, 4 Technicians and Instruments as well as supplies will be available for the successful candidate

Application including C.V , a short summary of previous scientific and educational experience, proposal for future research, list of publications as well as reprints or copies of publications or manuscripts (four copies of each) should be received at Karolinska Institutes Registratorskontor, Solnavagen 1,S-104 01 Stockholm, no later than Thursday June 13th, 1985. Applicants who wish to have a later deadline may submit material so that it reaches the above address no later than July 4th, 1985, provided that they, no later than June 13th, make clear to the Karolinska Institute (same address as above) that they wish to apply for the position, and that they state what material they will submit later

Further information can be obtained from Professor Jan-Oke Gustafsson (Tel. No. 8/7463351) and Dr. Rune Toftgord (Tel. No. 8/7463361). (W1897)A

Tenure track Assistant Professor positions are available in the Department of Pharmacology, University of Iowa, College of medicine. Applications are invited from well-trained individuals who possess the Ph.D. and/or M.D. degree and who are active in an area suitable for development of a vigorous research program related to molecular and cellular pharmacology or more traditional pharmacological disciplines. The University of Iowa is an equal opportunity/affirmative action employer. Submit curriculum vitae and names of three references to:

Search Committee
Department of Pharmacology
Bowen Science Building
University of Iowa

Bureau of Mineral Resources, Geology & Geophysics

Canberra

MARINE RESEARCH GEOPHYSICISTS

The Division of Marine Geosciences and Petroleum Geology in the Australian Bureau of Mineral Resources, Canberra, has vacancies for two Marine geophysicists, one being at senior level.

The principal research aims of the Marine Division are to define the regional geological framework, petroleum prospectivity and evolution of the sedimentary basins of Australia's extensive continental shelf and margins; further to develop new scientific concepts of basin structures and evolution of passive margins and also the active margins of the South Pacific. The main objective is the stimulation of ongoing programs of offshore petroleum exploration. The Division has recently acquired a research vessel with full multichannel seismic capability and seismic processing centre.

SENIOR MARINE GEOPHYSICIST:

to initiate and lead research and resource assessment programs on the Australian Continental Margins and in Australian Territorial waters.

The successful candidate should have a strong background of research experience and an international reputation. He/she should be experienced in multichannel seismic operations, seismic structural and stratigraphic interpretation and in aspects of geohistory analysis as well as have associated experience in other fields of marine geophysics and petroleum. **(Salary at SPRS/PRS level depending on qualifications and experience.)**

MARINE GEOPHYSICIST:

to undertake research and resource assessment programs on the Australian Continental Margins and in Australian Territorial Waters.

The successful candidates should have a history of research, be experienced in multichannel seismic operations, in seismic structural and stratigraphic interpretation and in at least some aspects of geohistory analysis. Associated experience in other fields of marine geophysics and petroleum would be valuable. **(Salary at SRS/RS level depending on qualifications and experience.)**

Qualifications for Both Positions:

A Ph.D (or equivalent) in marine geophysics together with demonstrated research ability.

Salary:

Research Scientist (RS) A$26001-32083
Senior Research Scientist (SRS) A$33209-38243
Principal Research Scientist (PRS) A$39692-45083
Senior Principal Research Scientist (SPRS) A$47501-52212

Conditions:

Conditions of service include superannuation for appointees, long service leave, cumulative sick leave, four weeks annual leave and assistance with removal expenses to Canberra. Permanent appointment is available to Australian Citizens. A term engagement will be considered for persons not meeting this criterion.

Canberra, the national capital, is located approximately 280km southwest of Sydney and has excellent educational, recreational and sporting facilities.

Applications together with full personal and professional details and the names of at least three referees should be sent to:

The Director,
Bureau of Mineral Resources,
GPO Box 378, Canberra ACT
2601, AUSTRALIA.

Applications close 21 June, 1985.

AUSTRALIA

Cell Biologist (PhD)

elf bio recherches

Elf Bio Recherches, a subsidiary of Elf Aquitaine and Sanofi, specialises in biotechnology. It is looking for a Cell Biologist for its laboratory of animal cell physiology and fermentation. This laboratory (2 scientists and 3 technicians) forms part of the recombinant animal cell technology unit. The position is to investigate the role of physiological factors involved in the expression of genes cloned into animal cells. Candidates should have a profound knowledge of animal cell physiology. Experience in medium or large-scale tissue culture will be an advantage. Knowledge of French would be appreciated. Elf Bio Recherches R&D facilities are located in the Toulouse area, in Southern France. Curriculum vitae and list of publications, together with a handwritten letter of application, should be sent to M. Fabre quoting reference **B/T 2018N.**

NATIONAL OPTICAL ASTRONOMY OBSERVATORIES

Associate Director-NOAO and Director-Cerro Tololo Inter-American Observatory — Applications and nominations are invited for the position of Director, Cerro Tololo Inter-American Observatory. The position reports to the Director NOAO and carries the added designation of Associate Director, NOAO. The incumbent will be a key member of a management team who plans and guides the development of NOAO as a program characterized by authoritative in-house science and imaginative and effective support to the user community. The position will be located in La Serena, Chile, and will carry explicit responsibilities for the planning, implementation, and oversight of AURA's program in Chile. The post offers excitement, challenge, and the promise of deep personal satisfaction derived from direct participation in the growth of an institution dedicated to the highest standards of in-house research, service to the astronomical community, and innovative approaches to astonomy. Applicants must have an earned doctorate in astronomy, or a closely related physical science, and a distinguished record of achievement in astronomy; evidence of leadership ability of a high order will also be sought. Interested individuals who feel that their background and temperament match the opportunities and inherent challenge of this position are invited to forward applications, with names of at least three people from whom a confidential evaluation can be sought to The Chair, Search Committee for Director CTIO, National Optical Astronomy Observatories, 1002 North Warren Avenue, Tucson, AZ 85719. Closing date for applications is July 31, 1985.

Further information can be obtained from Dr. John T. Jefferies, Director NOAO, at 602/881-1960. An EEO/AA Employer.
(NW1786)A

LUDWIG INSTITUTE FOR CANCER RESEARCH
UNIVERSITY OF SYDNEY

Post Doctoral Research Fellow

Applications are invited from Post Doctoral Scientists for a Research Fellow to join a group studying in vivo growth regulation of solid tumours, microenvironment and the effects of cytotoxic drugs Techniques currently in use employ tissue culture, syngeneic and xenogeneic animal tumours, and clinical material, with an excellent flow cytometry facility.

Applicants should possess a good background in cellular biology, and some experience in tumour growth kinetics would be an advantage

An attractive salary within the range A$22,614-A$25,246 p a will be negotiated.

Further information from Dr D. Hedley, (02) 692 3675/76.

Applilcations should be addressed to:

The Administrator,
LUDWIG INSTITUTE FOR CANCER RESEARCH,
Blackburn Building,
University of Sydney, NSW 2006 Australia

MRC
MEDICAL RESEARCH COUNCIL
CLINICAL PHARMACOLOGY UNIT
UNIVERSITY DEPARTMENT OF CLINICAL PHARMACOLOGY — OXFORD

NEUROCHEMIST

Applications are invited for a MRC SHORT-TERM NON-CLINICAL SCIENTIFIC post in this MRC Unit, tenable for 3 years in the first instance. Candidates with some post-doctoral experience will be preferred.

The successful candidate will be required to study the neuro-chemical mechanisms by which neurotransmitter systems respond to the short- and long-term effects of psychotropic drugs. Knowledge and experience of the biochemical mechanisms of neuronal membrane function, neurotransmitter synthesis and release, and techniques of brain slice and synaptosome incubation and stimulation would be advantageous This work has strong links with an active clinical psychopharmacology section.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information and an application form may be obtained from Professor D.G. Grahame-Smith, University Department and MRC Unit of Clinical Pharmacology, Radcliffe Infirmary, Oxford OX2 6HE (Oxford (0865) 241091), with whom applications, including a full curriculum vitae and the names and addresses of two professional referees, should be lodged by 24th June 1985.

(6613)A

AN ACTIVE FERTILITY AND IN VITRO PROGRAMME IS DUE TO OPEN AT THIS HOSPITAL ON 1st AUGUST 1985

Applications are invited for the following position, for which date of commencement will be by mutual agreement

TECHNICAL ASSISTANT/EMBRYOLOGIST

The successful applicant will be expected to undertake both routine laboratory and research work. Research is currently undertaken in collaboration with MRC (Carshalton) and the Institute of Animal Physiology (Cambridge)

Experience in mammalian embryology would be desirable and a PhD or MSc in reproductive physiology or embryology would be an advantage, but is not essential

The Hospital offers a generous salary and excellent benefit package.

Applicants should forward a Curriculum vitae, including the names of three referees to: The Personnel Department, Humana Hospital Wellington, Wellington Place, London NW8

Closing Date 22nd June 1985. (6599)A

Humana Hospital Wellington

Wellington Place London NW8 9LE

UNIVERSITY OF WISCONSIN-MADISON AQUATIC BOTANIST

RESEARCH ASSOCIATE (postdoctoral) position available by 1 June, 1985, for laboratory and lake studies on integrated control of Eurasian watermilfoil and impact of control strategies on water quality. Additional experience in water chemistry, limnology, or mycology desirable. Funding for two years. Salary competitive and commensurate with qualifications.

Send résumé, including the names of three referees, to: Dr. John H. Andrews, Department of Plant Pathology, 1630 Linden Drive, Madison, Wisconsin 53706.

An affirmative action-equal opportunity employer.

(NW1781)A

POST DOCTORAL RESEARCH

position is available to study the molecular biology of the enzymes involved in connective tissue degradation. A research background in biochemistry or molecular biology is advantageous. Applicants should send curriculum vitae and three references to Gregory I. Goldberg, PhD, Washington University School of Medicine, Box 8123, St Louis, Missouri 63110

Equal Opportunity/Affirmative Action Employer.

(NW1788)A

MOLECULAR IMMUNOLOGY POST-DOCTORAL SCIENTIST

Salary from £9,000

Celltech, a leader in the field of biotechnology, has achieved its present success in the space of five years. Pioneers in several areas, our achievements are based on the foundations of scientific excellence, innovation and commercial expertise.

Celltech's Molecular Immunology group is expanding its activities in the molecular cloning and expression of immunological targets, principally antibodies. We are looking for a Molecular Biologist/Immunologist, either a post-doc or a graduate expecting soon to finish a PhD. Experience in molecular or cellular immunology would be desirable.

We are an ambitious and forward looking company, which places as much emphasis on its people as its products. You will work in a small friendly team, gaining invaluable broad-based experience, with plenty of opportunity for advancement.

Please send a detailed c.v. to Jane Walley, Celltech Ltd., 244–250 Bath Road, Slough, Berks SL1 4DY, quoting Ref. 268.

CELLTECH

Express Dairy UK Ltd., one of the country's largest Dairy Food organisations has a vacancy in the Research and Development Department.

DEVELOPMENT ANALYST

c. £8,100

Working in a small team, this position involves analytical instrument evaluation and method development. You will be reporting to the Technical Advisor — Rapid Analytical Method Development and should be a Graduate in Analytical Chemistry with at least one year's experience in modern techniques of analysis associated with the food industry

A current driving licence is essential.

In addition to the salary detailed, 22 days holiday and membership of the Company's pension scheme are available on completion of the necessary qualifying period.

Application forms obtainable from:

Mr. G. D. Evans,
Personnel Officer — Central Staff,
Express Dairy UK Ltd.,
Block I, 430 Victoria Road,
South Ruislip,
Middlesex, HA4 0HF.
Tel: 01-845 2345 Ext. 3551/3370.

Immunodiagnostics

Cambridge BioScience Corporation, a biotechnology company specializing in infectious disease diagnostics offers exciting positions in its Hopkinton, Massachusetts laboratories. We are seeking advanced level scientists as well as research associates

Molecular Biology

- All levels with extensive background in recombinant-DNA, cloning and expression, minimum of 2 years academic or industrial experience

Virology/ Immunology

- Ph D level with experience in clinical virology
- Experience in hybridoma development
- Working knowledge of molecular virology

Cambridge BioScience offers a unique and stimulating environment and close working associations with academic institutions. **Qualified applicants should send resume and salary requirement to: Cambridge BioScience Corporation, Personnel Department, 35 South Street, Hopkinton, MA 01748.**

(NW1806)A

Cambridge BioScience

Experimental Nuclear Physicists

There are vacancies for experimental physicists to join the Nuclear Structure Division at Daresbury Laboratory, an establishment of the Science and Engineering Research Council which operates major national facilities for scientific research

The group is involved in carrying out and supporting a research programme on the Nuclear Structure Facility (NSF), a large tandem accelerator which is operating at up to 20 MV on terminal.

Senior Scientific Officer

Ref. DL/911

The successful applicant will be required to organise and direct work necessary for the operation, maintenance and development of major equipment for charged particle identification and detection used in programmes aimed at studies of nuclear collision dynamics, spectroscopy, and nuclei far from stability. Candidates will be expected to carry out research in conjunction with university users on the NSF and to play an active role in initiating and developing new programmes. Other duties will involve the overall coordination and scheduling of the scientific programme and the assessment of future needs for instrumentation and other facilities on the NSF.

Applicants (male or female) should have a good honours degree (or equivalent qualification) in physics and several years postgraduate experience in experimental nuclear research. A Ph.D qualification in nuclear physics and a period of relevant post-doctoral experience would be an advantage.

Higher Scientific Officer

Ref. DL/913

The successful applicant will be required to liaise with university research teams using the NSF. Candidates will also be expected to collaborate in nuclear research programmes and to play an active role in initiating and developing new programmes. Other duties will involve work on the design and development of major equipment through to commissioning, operation and maintenance. As a member of the in-house team of scientists he/she will be expected to provide expertise in the methods of experimental nuclear physics to aid and direct the technical and scientific support staff in operating the NSF and for diagnosing problems as they arise.

Applicants (male or female) should have a good honours degree (or equivalent qualification) in an appropriate discipline with a period of relevant post-graduate experience. A Ph.D degree in nuclear physics and a period of post-doctoral experience in experimental nuclear research would be an advantage.

The salary scales according to qualifications and experience for the Higher Scientific Officer and Senior Scientific Officer posts are £7,435 to £10,039 per annum and £9,329 to £12,050 per annum respectively. These salary scales are currently under review.

There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

CLOSING DATE: 30th June 1985.

For further information please write or telephone Dr. J. S. Lilley on Warrington (0925) 65000, Ext 558.

Application forms may be obtained from and should be returned quoting the appropriate reference number to: The Personnel Officer, Science & Engineering Research Council, Daresbury, Warrington, WA4 4AD. (6624)A

Daresbury SCIENCE & ENGINEERING RESEARCH COUNCIL

Faculty Position available, tenure-track, in molecular genetics, with a special interest in membranes. Applicants should have research background in recombinant DNA technology (preferably also in somatic cell genetics) and working knowledge of membrane proteins. M.D. and/or Ph.D. in appropriate field required. Successful candidate will hold tenure-track appointment (Assistant or Associate Professor, depending upon qualifications) in Department of Physiology and Molecular Biophysics at Baylor College of Medicine. Joint appointments in relevant academic departments also possible. Laboratory space and basic equipment provided and initial laboratory support available. Successful candidate will devote majority of his/her effort to establishing and maintaining an independent research program related to the main interests of the Department. The Department is building a strong program in membrane biophysics with expertise in electrophysiology, membrane biochemistry, reconstitution, and modelling. **Send vita, a brief description of past and present research experience, and names of three or more references to**

Dr. A. M. Brown, Incoming Chairman,
Physiology and Molecular Biophysics Department

Baylor College of Medicine,
One Baylor Plaza,
Houston, Texas 77030.

An Equal Opportunity A/A Employer

(NW1814)A

SENIOR SCIENTIFIC PROGRAMMER

National Optical Astronomy Observatories

The National Optical Astronomy Obervatories

(NOAO) needs a senior level programmer for its Detector R&D Program in Tucson. Working with scientists and engineers, the position involves development of software to operate state-of-the-art infrared arrays and signal processing equipment for astronomical instrumentation. We require skills in the development of real-time software for data acquisition and process control applications and date reduction and analysis programs. Applicants should have experience in FORTRAN and one of the structured languages such as "C". Experience in a real-time programming environment and software signal procesing is required. Knowledge of FORTH, UNIX , and DEC computers is desirable. An Electrical Engineering or Computer Science degree and at least five years experience as a programmer are required. Other degree background will be considered with more extensive programming experience.

The NOAO, headquartered in Tucson, Arizona, operates Kitt Peak National Observatory near Tucson; National Solar Observatory sites at Sacramento Peak, New Mexico, and on Kitt Peak; Cerro Tololo Inter-American Observatory in Chile, and the Advanced Development Program in Tucson.

Offering forefront technology challenges, and unclassified workplace, and a Sunbelt location, we are an EEO/AA employer with an excellent compensation package, including 24 days annual vacation and, after one year, a fuly vested retirement plan.

Send résumé in confidence to: Judy Ruffino, Personnel Manager, P.O. Box 26732, Tucson, Arizona 85726.

Equal opportunity employer. (NW1804)A

MACROMOLECULAR CRYSTALLOGRAPHER

Three-year Postdoctoral Research Associate position. Seeking motivated, talented person with experience in experimental aspects of structure determination to conduct x-ray diffraction studies. Several ongoing projects at different stages under the overall theme of intermolecular interactions. Excellent facilities for data collection, reduction, and analysis: rotating anode generators, area detector, oscillation/precession cameras, 2 VAX 11-750s, node to CRAY, color vector and raster graphics. Exciting work environment within a strong departmental structure group including six faculty crystallographers. Salary negotiable. Superb working setting in new building located on cliffs overlooking ocean. Send C V and three references to:-

Elizabeth Getzoff or John Tainer, Department of Molecular Biology — MB3, Research Institute of Scripps Clinic, 10666 North Torrey Pines Road, La Jolla, CA 92037 (NW1799)A

THE ROYAL VETERINARY COLLEGE
University of London

Division of Preclinical Studies
Department of Physiology, Biochemistry and Pharmacology

Lecturer in Biochemistry

Applications are invited from veterinary, science, or medical graduates for a post involving both teaching and research which it is hoped to fill by 1st October 1985. An interest in metabolism and previous experience in lipid and lipoprotein biochemistry would be of advantage.

Salary Scale (under review): £8,753 to £16,158 including London Allowance. Universities Superannuation Scheme. Removal expenses up to £1,400 reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. (Tel: 01-387-2898).

Closing date for applications: 17 June 1985 (6630)A

UNIVERSITY OF NATAL
DEPARTMENT OF ZOOLOGY
ZOOLOGY

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin for appointment to the post of.

LECTURER IN BIOLOGY

Minimum qualifications would be a PhD in Zoology, Botany, Biology or a closely allied field and/or suitable academic or research experience.

The successful applicant will be responsible for teaching a first year introductory course, which is essentially a service for students in the Faculty of Agriculture. The four major areas covered by the course are Cell Biology, Plant Anatomy and Development, Animal Physiology, and the Ecology and Evolution of Animals and plants. No particular area of expertise is required beyond a sound and comprehensive knowledge of biology, but the appointee will be encouraged to actively participate in research and to supervise post-graduate students.

The appointment carries an attractive salary package, details of which are obtainable from the Staffing Section on request (telephone 0331-63320). The salary offered will be determined according to the qualifications and/or experience of the successful applicant.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, service bonus, staff bursary, housing loan, and subsidy schemes, long leave conditions and travelling expenses on first appointment, are available from the Registrar, University of Natal, PO Box 375, Pietermaritzburg, South Africa, 3200, with whom applications on the prescribed form must be lodged not later than 28 June 1985 quoting reference PMB 29/85.

Application forms for overseas applicants are available from the Secretary, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. (W1895)A

COMMONWEALTH AGRICULTURAL BUREAUX

THE LEADING WORLD AGRICULTURAL INFORMATION SERVICE FOR SCIENTISTS AND TECHNOLOGISTS

SCIENTIFIC INFORMATION OFFICER

REQUIRED AT THE
COMMONWEALTH BUREAU OF PLANT BREEDING AND GENETICS, CAMBRIDGE

Duties:
Preparing abstracts for the Journal *Plant Breeding Abstracts*, which covers world scientific literature in this field: indexing, and answering scientific enquiries.

Qualifications:
A degree in botany, genetics, or a related subject is essential, plus a reading knowledge of at least one European language (Slavonic languages preferred) and the ability to write good English. Applicants must be able to render the contents of scientific publications into concise, accurate and readable abstracts.

Salary:
In the scales £5,909—£8,153 p.a., £7,435—£10,039 p.a. Starting salary according to qualifications and experience.

Application forms and further particulars from
Commonwealth Bureau of Plant Breeding and Genetics
Department of Applied Biology
Pembroke Street, Cambridge CB2 3DX
Tel. No: Cambridge (0223) 358381, etxn.216.
Closing date for applications: 20th June, 1985.

(6689)A

Bureau of Mineral Resources
Geophysics Division
Canberra
GEOMAGNETISM SECTION MANAGER
A$34757 - A$37028

The Geomagnetism Section of the Division of Geophysics, Bureau of Mineral Resources, comprises a staff of 15. The Section is responsible for operating the magnetic observatories and conducting magnetic surveys in the Australian and Antarctic regions, and also runs a modern palaeomagnetic facility. Mission oriented research is carried out in the fields of solid-Earth geomagnetism and palaeomagnetism.

Duties:
The Manager, acting under the Section Head, is responsible for administration of the section, and the co-ordination of magnetic (including palaeomagnetic) observatory and survey operations. The person appointed will be expected to initiate and participate in aspects of the research program

Qualifications:
An appropriate degree or equivalent, ability to manage a scientific team, experience in magnetic (including palaeomagnetic) observatory and survey operations, the ability to carry out original research in geomagnetism.

Conditions:
The BMR is part of the Australian Public Service. To qualify for permanent appointment, applicants must be Australian citizens. Non-citizens may be appointed under a 3-year contract, with the expectation that they seek permanent appointment. Conditions of service (pension scheme, leave entitlement, etc.) are those pertaining to the Australian Public Service. Moving and settling-in allowances are paid to persons, and their dependent families, appointed from overseas.

Canberra, the national capital, is located approximately 280km southwest of Sydney and has excellent educational, recreational and sporting facilities.

Applications, including a curriculum vitae, statement of research interests, and names of professional referees should be addressed to: Staff Section, Bureau of Mineral Resources, P.O. Box 378 Canberra, A C.T. 2601, Australia.

Please quote reference: Position No. 2409, Geomagnetism. Applications should be submitted before 30th June 1985 (W1899)A

AUSTRALIA

Consejo Superior de Investigaciones Cientificas
INSTITUTO CAJAL
(Madrid, Spain)

Three permanent research positions will be available in 1985 at The Cajal Institute for Neurobiology. One of the positions is open for neurophysiologist and the other two for specialists in any other branch of Neuroscience. The appointments will be at the Research Associate level. Applicants must be Spanish citizens and have a M.D. or Ph.D. degree.

Further information may be obtained from:
The Director, Instituto Cajal, Veláquez 144, 28006-Madrid, Spain. (w1889)A

Postdoctoral or Research Associate Position

Available July 1, 1985. Project involves function of actin isoforms, post-translationally modified tubulin species, and microtubule-associated proteins. Biochemisty or molecular biology background is desirable; the lab uses these, as well as peptide antibody techniques, HPLC, cell culture, and immunostaining. Salary depends on experience. Send curriculum vitae and the names of three references to.

Dr. J.C. Bulinski, Department of Biology, University of California, Los Angeles, CA 90024. (NW1805)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following positions

Research School of Earth Sciences

POSTDOCTORAL FELLOW/RESEARCH FELLOW/ SENIOR RESEARCH FELLOW NOBLE GAS GEOCHEMISTRY

Applications are invited for an appointment in the School's Geochronology and Isotope Geochemistry Group, the field of interest being noble-gas geochemistry The appointee will work with Dr Ian McDougall, Senior Fellow, in developing research in this field, which is new to the School. The School wishes to make the appointment at the Research Fellow level, but will be prepared to consider applications at the level PDF or SRF

Noble gas investigations are being initiated to assist in elucidation of the geochemical evolution of the mantle, the mantle-crust system, and the atmosphere Research initially will concentrate on mantle-derived rocks, with subsequent development of studies on fluids in the crustal environment Provision of a suitable high-resolution gas-source mass spectrometer is in hand, and construction of appropriate extraction lines is planned.

Persons with suitable backgrounds in the physical sciences, and with particular interests in geochemistry, are encouraged to apply Experience in noble gas studies on geological samples would be a great advantage.

The appointee will assist in developing the laboratory facilities, and will be expected to undertake discrete projects within this broad field of study Active collaboration with other workers in isotope geochemistry is envisaged. Enquiries may be directed to Dr I McDougall (062 49 4136)

Closing date. **19 July 1985.** Rf: ES/1.5.1.

Faculty of Science
DEPARTMENT OF ZOOLOGY
POSTDOCTORAL FELLOW

The successful applicant will work on a NH & MRC funded project involving gene cloning of sheep parasites particularly larval tapeworms and liver fluke Particular interest will be centred on those genes which code for antigens that are involved either in resistance to reinfection or immunopathological phenomina. A principal objective will be to obtain expression of these antigens in prokaryotic systems Experience in gene cloning techniques is essential and some knowledge of immunological procedures would be highly desirable The successful applicant will work in the Centre for Recombinant DNA Research, Research School of Biological Sciences (Executive Director. Professor J A Pateman FRS). The position is funded for 3 years Previous applicants need not reapply as all applications will be considered

Further information is available from Dr M J Howell, (062) 49 3060 or (062) 49 4225

Closing date **15 July 1985.** Ref: FS/1 5.1

CONDITIONS OF APPOINTMENT: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow $A21,411-$24,528 pa; Research Fellow $A24,840-$32,634 pa; Senior Research Fellow $A34,699-$41,390 pa Current exchange rate is $A1 00 – Stg 0 48.

Grants are provided towards travel and removal, though special conditions may apply to persons appointed to externally funded positions Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities Maternity leave is available The University reserves the right not to make an appointment or to make an appointment by invitation at any time **Applicants should quote the advertisement reference when requesting further particulars and when submitting applications, which should be sent to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. General Information also available from the Secretary General, Association of Commonwealth Universities (Appts) 36 Gordon Square, London WC1H 0PF**

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER

(W1880)A

UNIVERSITY OF TORONTO
DEPARTMENT OF BOTANY
POSTDOCTORAL FELLOW

required to work in group studying molecular basis of metal-tolerance in micro-organisms and higher plants Applicants should have experience in recombinant DNA techniques; knowledge of microbial physiology and plant ecology an advantage. Salary is in range of $21,500 Canadian Position is available immediately. **Please send detailed letter and C.V., plus three letters of reference to Prof. T.C. Hutchinson, Department of Botany, University of Toronto, Toronto, Ontario, Canada M5S 1A1.** (NW1809)A

VICE PRESIDENT FOR RESEARCH
THE UNIVERSITY OF GEORGIA

The University of Georgia invites nominations and applications for the position of Vice President for Research.

Located in Athens, Georgia, The University of Georgia is the nation's oldest chartered state university. The University ranks among the top 50 research institutions in the country and operates with annual research expenditures in excess of $80 million across its 13 schools and colleges.

The Vice President for Research will administer the University's research resources, serve as an executive officer of the University and report to the President. He/she will facilitate and coordinate a vigorous expansion of competitively-funded research programs, and seek new avenues for creative partnerships with the private sector and government agencies She/he will exert strong leadership in the organisation and funding of new, interdisciplinary research programs, and will formulate reward and incentive systems for faculty participation in sponsored research

Nominees/applicants should have a record of executive-level accomplishments, knowledge of current R&D environments encompassing national and international perspectives in private, public, and governmental sectors, and should possess a working knowledge of higher education, including the nature and scope of university research activities. Candidates should have the terminal degree or equivalent experience in their discipline, and credentials suitable for appointment at the level of professor in the University.

Nominations should include the nominee's address and telephone number. Applications should include a letter of interest, a curriculum vitae, and the names and addresses of 5 persons who can serve as references. The closing date for receipt of completed applications is **July 15, 1985.** The position may be occupied as early as January 1, 1986

Address all nominations and applications to:

Vice President for Research Search Committee
c/o Dr Luis M. Proenza
Office of the President

SCOTTISH CROP RESEARCH INSTITUTE
DIRECTOR

The Governing Body of the Scottish Research Institute invites applications for the post of Director which will become vacant on the retirement of Professor C E Taylor CBE in March 1986.

SCRI, which is funded by an annual grant from the Department of Agriculture and Fisheries for Scotland, is a major crop research institute within the Agricultural and Food Research Service. It's research programme requires a wide range of scientific disciplines associated with the production and breeding of arable and horticultural crops.

Candidates should have an established record of scientific leadership and the capability to manage an organisation with over 300 staff.

Salary; £26,909 per annum non-contributary superannuation scheme

The Institute is an equal opportunities employer

Further particulars can be obtained from Mr N D Anderson, The Secretary to the Governing Body

Applications accompanied by a full curriculum vitae and the names and addresses of three referees should be lodged with the Secretary to the Governing Body, Scottish Crop Research Institute, Invergowrie, Dundee DD2 5DA.

Closing date 12 July 1985. (6679)A

DROSOPHILA DEVELOPMENT

University of Arizona

Two postdoctoral positions available to work on molecular aspects of pattern formation and morphogenesis in Drosophila. One position state-funded at the level of Visiting Lecturer, with opportunities for teaching. Salary commensurate with experience Send CV, statement, and names, addresses, and telephone numbers of at least three referees to. Dr. Danny Brower, Department of Molecular & Cellular Biology, Biosciences West Building, University of Arizona, Tucson, AZ 85721, USA Position to begin Fall 1985 An equal opportunity/affirmative action employer (NW1801)A

TWO RESEARCH ASSOCIATE POSITIONS

Available immediately. Experience in proteins and recombinant DNA. Salary $18,000 to $22,000
Send CV and three references to Dr O P. Bahl, Dept. of Biological Sciences, SUNY at Buffalo, Cooke Hall 347, Buffalo, NY 14260. Equal Opportunity/Affirmative Action Employer (NW1811)A

Post Doctoral Fellow Experimental Pathology

At Smith Kline & French we wish to appoint a Post Doctoral Fellow within a new laboratory of our expanding Pathology Department.

The work will be to apply cell and organ culture techniques to the investigation of cell pathology related to new and model compounds. Integrated projects with histopathologists, EM and clinical pathologists will also be involved.

A PhD and post doctoral experience in the use of *in vitro* techniques applied to experimental pathology is required. Experience in bone marrow CFU and lymphocyte culture would be an advantage.

We offer a competitive salary and benefits for this two year fixed term appointment.

Please write for an application form or send a detailed CV outlining your qualifications and experience quoting reference number N/123/JW to John Ward, Personnel Officer, Smith Kline & French Research Limited, The Frythe, Welwyn, Herts AL6 9AR.

SK&F

POSITION OPEN

RESEARCH ASSOCIATE POSITION

available immediately to study the dynamics of membrane phase transitions using a novel volume-perturbation kinetic calorimeter which we have developed We are seeking a person with a Ph.D in Biochemistry, Biophysics or related field for a Research Associate position to work on this project.
Our calorimeter measures the thermodynamic phenomenon associated with phase transitions in membrane systems via temperatures and pressure changes and optical properties. The person we seek must be able to synthesize artificial lipid membranes in pure form and mixed with other constituents, and be able to reconstitute protein recombinant systems so the proteins retain their native functions. This person will conduct experiments, do some hardware modification, and modify and use computer software for data acquisition and experimental analysis. The individual must have a working knowledge of membrane systems. He/she must also be experienced with computer hardware and software methods for data acquisition, instrument control, data analysis and modelling studies.
Send Curriculum Vitae and names of referees to Dr. Michael L. Johnson, Department of Pharmacology, University of Virginia, Charlottesville, Virginia 22908. An Equal Opportunity/Affirmative Action Employer. (NW1813)A

CELL BIOLOGIST

UNIVERSITY OF ALABAMA AT BIRMINGHAM

Applications are invited for two senior, tenured positions in the Department of Cell Biology at the level of Associate or Full Professor. Candidates must have achieved international recognition in cell or molecular biology, have a productive and well funded research program and be willing to move the program to Birmingham. Preference will be given to individuals employing molecular techniques to study the structure and function of cell components, growth control, regulation of gene expression, cell development or motility. Successful candidates will be offered nationally competitive salaries, excellent laboratory space and facilities, and an outstanding research environment in a rapidly expanding medical center Ample opportunities exist for teaching in the Schools of Medicine and Dentistry including gross anatomy, neuroanatomy, histology or in a new graduate program in cell biology.

Applicants should send a curriculum vitae and a brief description of past and present research experience and the names of three or more references by July 1, 1985 to: B. R. Brinkley, PhD, Professor and Chairman, Department of Cell Biology and Anatomy, Schools of Medicine and Dentistry, University of Alabama at Birmingham, University Station, Birmingham, Alabama 35294. An Equal Opportunity/Affirmative Action employer. (NW1785)A

Southampton THE UNIVERSITY

Department of Chemistry

Production and properties of Silicon-on-Insulator materials

A Postdoctoral position will be available from October 1985 for a Physical Chemist or Physicist to participate in a fundamental study of the production of new semiconductor materials. The project will employ a novel combination of techniques, including electrochemistry and in-situ ellipsometry applied to porous silicon substrates, which are being evaluated as the basis of the next generation of fast devices.

Previous experience in electrochemistry or spectroscopy would be an advantage, and some knowledge of computer programming or computerised instrumentation is necessary. The salary will be at a point on the SERC 1A scale commensurate with the age and experience of the appointee

Applications together with the names of two referees should be sent as soon as possible to: Dr. R. Greef, Chemistry Department, The University, Southampton SO9 5NH, UK, from whom further information can be obtained. (6670)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (UNIVERSITY OF LONDON)

DEPARTMENT OF MEDICAL PROTOZOOLOGY

MOLECULAR BIOLOGIST

A post-doctoral position will shortly become available in this Department for a 3-year period for a suitable individual who wishes to join a team investigating the mechanisms of drug-resistance in malaria, under the direction of the Head of the Department, Professor W Peters. The project will be carried out in close association with the members of the Wolfson Unit of Molecular Medical Microbiology and Parasitology who are based in this Department. Applicants must have training and experience in recombinant DNA technology and will work closely with other members of the team who are investigating the very practical problem of drug-resistant malaria from other points of view, including the evaluation in depth of promising new antimalarial compounds. The appointment, which will be for up to three years in the first instance, carries a starting salary in the range £8,543 to £13,173 per annum.

Candidates should send, as soon as possible, a full curriculum vitae describing their previous training, research experience and research interests, together with the names of three referees, to the Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1E 7HT. Please quote reference MP2.

(6632)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF BIOCHEMISTRY

Positions are available for a temporary lecturer, postdoctoral worker and SERC-CASE student. All posts are tenable from the 1st of October, 1985.

The temporary lectureship is available for 3 years and results from an MRC-replacement scheme award to Dr H C Nimmo. The appointee would be encouraged to undertake research and to collaborate with existing groups within the Department.

The postdoctoral position is available for 2 years to work with Professor Houslay's group on guanine nucleotide regulatory proteins and their interaction with adenylate cyclase. This appointment is funded by the MRC and will be made within the first three points of the 1A salary scale for research workers.

An SERC-CASE studentship award for the study of a PhD is available to work jointly with Professor Houslay at Glasgow and Dr Baxter at Glaxo. This project is aimed at understanding the physiological importance of the tyrosine kinase activity associated with the insulin receptor. The conditions of this award are as generally applicable to research council studentships.

Further information may be obtained from, and informal enquiries may be made to, Professor M D Houslay, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ, to whom application (3 copies), should be made by 30th June, 1985. (6691)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ZOOLOGY

POSTDOCTORAL RESEARCH ASSOCIATE IN NEUROBIOLOGY

Applications are invited for a postdoctoral Research Associate to work with a small group, supported by the SERC investigating the physiology and structure of insect brain neurones. Interests are both in the operation of synapses which identified visual neurones make amongst each other, and in the function of these neurones in the control of behaviour. In particular, we plan to compare the membrane properties and synaptic structure of different neurones, with the aim of understanding more about the roles of spikes in regulating transmitter release from neurones. Applicants should have experience in ultrastructural or in electrophysiological techniques, and are required either to have or to be close to completing a PhD. The appointment is for 3 years tenable from 1st July 1985 (deferable for up to 6 months).

Salary will be up to £8,450 per annum on the Range 1A scale (£7,520 - £12,150) according to age, qualifications and experience.

Applications (2 copies of curriculum vitae and research experience), plus names of 2 referees, or enquiries to: Dr P J Simmons, Department of Zoology, University of Newcastle upon Tyne NE1 7RU not later than 13th June 1985.

(6627)A

NATURE CONSERVANCY COUNCIL

(Commissioned Research —)

(Contract Post)

DEPARTMENT OF ENTOMOLOGY

HIGHER SCIENTIFIC OFFICER DATA HANDLING/ ENTOMOLOGIST

Applications are invited for a one year contract post funded by the Nature Conservancy Council, to be based in the Entomology Department, Rothamsted Experimental Station, Harpenden, Herts. The successful applicant will be responsible for analysing light trap data for moths gathered by the Rothamsted Insect Survey. The project will investigate whether any long term trends are apparent for the polulations of particular moth species, or for the fauna of selected sites. The RIS moth data is stored on computer file and so previous computing experience is essential, and some familiarity with the British moth fauna would be an advantage.

Qualifications. Candidates should have a first or second class honours degree, or equivalent, in computing studies or in zoology and with at least two years relevant postgraduate experience.

Salary depending on age and qualifications Higher Scientific Officer £7,435 rising to £10,039 per annum.

Application forms and further details are available from Miss B A Meredith, Personnel 1, Nature Conservancy Council, Northminster House, Peterborough PE1 1AU.

The closing date for receipt of completed application forms is 21 June 1985 The Nature Conservancy Council is an equal opportunity employer. (6653)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY PATHOLOGY

MOLECULAR VIROLOGY UNIT

A molecular virology unit has been established to develop novel vectors for the expression of viral antigens in mammalian systems. This unit works in close collaboration with virilogists and molecular biologists in this department and at the Beatson Institute.

Three positions, supported by the National Institutes of Health, are immediately available. Applications are invited for 2 post-doctoral fellows (salary range £8,450 to £10,720 per annum) and a research assistant (£6,600 per annum). The research assistant may apply to register for a higher degree.

The applicants should have experience in recombinant DNA technology and a background in virology would be an advantage. Applications should be sent to, and further particulars may be obtained from, Professor W F H Jarrett, FRS, University of Glasgow Veterinary School, Bearsden, Glasgow G61 1QH (telephone number 041-942 2301). (6692)A

UNIVERSITY OF LONDON THE CARDIOTHORACIC INSTITUTE

DEPARTMENT OF MEDICINE

NEW BLOOD APPOINTMENT

Applications are invited for a "New Blood" appointment in the Department of Medicine. The successful candidate is likely to be a clinical or non-clinical scientist with experience in the application of immunological and cell biological methods to study of the pulmonary macrophage. He or she will be expected to be sufficiently experienced to contribute new basic scientific ideas in this area and to carry these through experimentally in the current programme of research being conducted in the Department of Medicine into the cellular, biochemical and host defence aspects of pulmonary disease. A clinical appointee would be expected to co-ordinate the programme of laboratory research as it is applied to in-patients and out-patients, and to participate in the teaching activities of the Department.

Candidates should not hold a permanent University appointment in the UK. Appointment will be on the Clinical or non-Clinical Lecturer scale. A London Allowance is payable.

Applicants should apply by letter, enclosing 8 copies of their curriculum vitae, a statement of not more than 500 words on why they are applying for this post, and naming 3 referees to The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP from who further particulars can be obtained. Closing date for application 21 June 1985.(6645)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF CHEMICAL AND BIOCHEMICAL ENGINEERING

POSTDOCTORAL AND POSTGRADUATE RESEARCH ASSISTANTS RESEARCH TECHNICIAN

Applications are invited from biochemical and chemical engineers, biochemists and microbiologists for four posts in the Department of Chemical and Biochemical Engineering to work on two research programmes.

(1) Biocatalytic reaction involving water-insoluable organic compounds (supported by SERC).

(2) Extended use of biocatalysts (supported by DTI and seven companies through The Institute for Biotechnological Studies).

Appointments for three years starting as soon as possible will be made on the 1A and 1B scale for research assistants, and grade 3 scale for the technician.

Applications including CV and names and addresses of two referees should be sent to Professor M D Lilly, Department of Chemical & Biochemical Engineering, University College London, Torrington Place, London, WC1E 7JE. (6652)A

THE NATURE CONSERVANCY COUNCIL

SENIOR SCIENTIFIC OFFICER

Co-ordinator for remote sensing of the environment

The successful candidate will be required to assist with the management and co-ordination of the National Countryside Monitoring Scheme. The duties will include advising NCC staff on digital cartography and the development of NCC's use of satellite imagery for monitoring purposes. Other responsibilities will include liaising with the Department of Environment, Countryside Commission, Countryside Commission (Scotland), Institute of Terrestrial Ecology and other organisations concerned with the monitoring of countryside feature through remote sensing.

Candidates should have a degree in an appropriate subject and at least four years post graduate experience. Essential experience will include digital cartography, photogrammetry, statistical analysis and sampling strategies involving remote sensing, the ability to write and edit the necessary computer software and management experience of remote sensing programmes.

Salary range: £9,329 to £12,050.

For further details and an application form, please contact Mr S Woodfield, Personnel 1, Nature Conservancy Council, Northminster House, Peterborough PE1 1AU to whom completed forms should be returned by the 19 June 1985.

The Nature Conservancy Council is an equal opportunity employer (6654)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GEOLOGY

Applications are invited for the post of

RESEARCH ASSISTANT/ SENIOR RESEARCH ASSISTANT/ RESEARCH ASSOCIATE

to work on a study of fault geometry and mechanics using data from colliery plans and records. Applicants should be graduates in a branch of Earth Sciences and have a good grounding in either structural geology or geophysics. An interest in computing and/or quantitative methods in geology would be an advantage. There will be no opportunity to register for a higher degree. A candidate currently registered for a higher degree will only be considered if thesis submission is imminent.

Appointment will be from 1st July, 1985, initially for one year. Initial salary will be within the range £6,600 — £9,390 per annum.

Applications, together with the names of three referees, should be received not later than 14th June, 1985, by The Registrar, The University, PO Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained.

Quote ref RV/294/N. (6662)A

VICTORIA UNIVERSITY OF WELLINGTON

DEPARTMENT OF BIOCHEMISTRY

TEMPORARY LECTURER IN BIOCHEMISTRY

Applications are invited for the above position, which is available from 1 February 1986. Applicants should have recently obtained a PhD in contemporary biochemistry. The most desirable areas of expertise are those of molecular biology (in particular recombinant DNA technology), molecular enzymology or protein chemistry. The research interest of the Department lie in mechanistic studies in biochemical pharmacology and toxicology with a bias towards projects of agricultural significance The appointeee will be expected either to redirect his or her expertise into existing projects or to initiate new research compatible with departmental interests. Experience in relevant fields such as biochemical pharmacology or insect biochemistry or toxicology would therefore be advantageous

Salary will be the range NZ$23,622 — NZ$27,928 per annum. The appointment will initially be for a period of two years. Extension for a third year may be possible depending on the outcome of a review of the Life Sciences at Victoria University.

Conditions of Appointment and method of application are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or the Administrative Assistant (Appointments), Victoria University of Wellington, Private Bag, Wellington, New Zealand, with whom applications close on 26 July 1985. (W1901)A

THE SCHOOL OF PHARMACY

University of London

DEPARTMENT OF PHARMACEUTICAL CHEMISTRY

POSTGRADUATE Research Opportunities in Pharmaceutical Chemistry

Applications are invited for a number of positions for postgraduate research leading to higher degrees Candidates should have or expect to have a good honours degree in pharmacy, chemistry, biochemistry or biophysics.

Research Council and industrially sponsored projects on offer include.

(a) Diffusion and light scattering of biopolymer systems
(b) Applications of fast atom bombardment mass spectrometry in pharmaceutical and biological chemistry
(c) Chemical and biological NMR spectroscopy; and
(d) Synthesis and structure of natural products and peptides.

Applications should indicate area(s) of interest, giving names of two academic referees and two copies of CV and, to be sent to: Personnel Officer, The School of Pharmacy, 29/39 Brunswick Square, London, WC1N 1AX (6674)A

MICROBIOLOGIST

Molecular Immunology Division

The Molecular Immunology Division of Allelix Inc. is seeking a microbiologist with experience in the culture, maintenance and isolation of clinically important infectious agents for the Product Development Group. The successful candidate will work in a team developing rapid diagnostic immunoassays for the diagnosis of infectious diseases. This individual will possess a Ph.D. in microbiology and at least two years' post-doctoral experience in clinical microbiology. Experience in immunoassay and protein chemistry techniques will be advantageous.

Allelix provides the opportunity to learn from and interact with experienced staff scientists, in addition to the immediate project leader, in a well-equipped laboratory. Salaries and benefits are at fully competitive levels.

Interested candidates are asked to send complete resumés, including three references and quoting file number MI001, to:

Dr. J.G.R. Hurrell

Allelix INC

6850 Goreway Drive
Mississauga, Canada

(NW1810)A

UNIVERSITY OF LEICESTER

DEPARTMENTS OF ZOOLOGY AND OBSTETRICS AND GYNAECOLOGY

SENIOR DEMONSTRATOR IN REPRODUCTIVE PHYSIOLOGY

Applicants are invited for a post of Senior Demonstrator in Reproductive Physiology. This will be a joint appointment in the Department of Zoology and Obstetrics and Gynaecology Applicants should have experience in tissue culture and/or the culturing of mammalian embryos, and should preferably be post-doctoral. The appointee will be required to assist in collaboration with the two departments in developing a programme of extracorporeal fertilisation There will also be a teaching commitment in the area of cell and developmental biology in the Department of Zoology. The appointment will be for two years.

Initial salary will depend on age and experience on the scale £7,520 to £12,150 (under review).

Further particulars from the Registrar (Appointments), University of Leicester, University Road, Leicester LE1 7RH (telephone 0533 554455 ext 233), to whom applications on the form provided should be sent by 17 June 1985. Informal enquiries can be made to Professor H C Macgregor, Department of Zoology Telephone 0533 554455 ext 115 (6642)A

UNIVERSITY OF THE WEST INDIES

St Augustine, Trinidad

DEPARTMENT OF MECHANICAL ENGINEERING, INDUSTRIAL ENGINEERING PROGRAMME

LECTURER/ ASSISTANT LECTURER

Applications are invited for the post of Supernumerary Lecturer/Assistant Lecturer in the Department of Mechanical Engineering, Industrial Engineering Programme, specialising in Operations Research and Production/Investment Planning. The appointment will be two years.

Salary scales: Lecturer: TT$54,708 × 1,908 – $66,156 (Bar) × 1,908 – $77,604; Assistant Lecturer: TT$45,480 × 1,908 – $49,296. FSSU Unfurnished accommodation if available at 10% or furnished at 12% or housing allowance of 20% of pensionable salary. Up to five full economy passages on appointment and on normal termination. Study and Travel Grant

Detailed applications giving qualifications and experience and naming three referees to the Campus Registrar, University of West Indies, St Augustine, Trinidad, West Indies. Details of post sent to all applicants, but also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1902)A

CANCER RESEARCH

The AMC Cancer Research Center seeks to expand its laboratory and clinical research programs. Individuals at all levels, from Post-doctoral Fellows to Department Chairmen, will be considered. Current interests include tumor cell biology, tumor immunology, experimental hematology, monoclonal antibodies, cell kinetics, nucleic acid metabolism, nuclear magnetic resonance imaging, as well as clinical and national community research and control programs. Scientists (Assistant Professor equivalent) will be expected to vigorously develop independent research. Senior Faculty must be of national prominence and hold significant external funding. Opportunities exist for collaboration and growth Facilities, equipment and initial research support are available. Clinical resources on campus include a 32 bed inpatient unit, outpatient clinics and services. Individuals with interests bridging laboratory and clinical cancer research are particularly sought. Send Curriculum vitae and other pertinent information to:

Dr. Philip Furmanski
Associate Director
AMC Cancer Research Center
1600 Pierce Street
Denver, Colorado 80214

(NW1798)A

UNIVERSITY OF THE WEST INDIES MONA, JAMAICA

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the following posts in the University of the West Indies

LECTURER/ASSISTANT LECTURER

It is desirable for teaching purposes that the successful applicant should have a broad training in Biochemistry. Certain areas of research interest are particularly welcome, eg plant biochemistry, toxicology, nutrition, immunology, biotechnology. Duties to be assumed as soon as possible.

Salary scales (under review): Lecturer (non-medical) J$23,688×768 - 28,296 (B)×825-33,246. Assistant Lecturer (non-medical) J$20,379×717-21,813.

Up to five full economy class passages plus baggage allowance up to US$900 on appointment and normal termination. Special allowance up to US$900 on appointment and normal termination. Special allowance up to US$300 for shipment of academic books and teaching/research equipment on appointment. Unfurnished accomodation at 10% of pensionable salary or housing allowance of 20% of pensionable salary. UWI contribution of equivalent of 10% of salary to Superannuation Scheme. Subsidized Health Service. Annual Book Allowance. Annual Study and Travel Grant for self, spouse and three children. Transportation allowance to persons who own and operate a motor vehicle.

Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status, and the names and addresses of three referees should be sent as soon as possible to the Campus Registrar, UWI, Mona, Kingston 7, Jamaica. Applicants in the UK should also send one copy to the Assistant Secretary General (Appointments), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. Further details obtainable from either source. (W1905)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
London W1P 6DB
(University of London)

DEPARTMENT OF ANATOMY AND BIOLOGY AS APPLIED TO MEDICINE

POST-DOCTORAL RESEARCH ASSISTANT 1A

Applications are invited for this SERC supported post, tenable from October 1, 1985 (or earlier), to work for 3 years on cell contact and movement using advanced fluorescence methods.

Written applications, including the names of two referees, should be sent to Professor D Gingell at the above address. (6650)A

TECHNICAL UNIVERSITY OF GRAZ, AUSTRIA

The Chemistry Department of the Technical University of Graz invites applications for the position of a

FULL PROFESSOR OF PHYSICAL CHEMISTRY

at the Institute of Physical and Theoretical Chemistry. Applicants are expected to be internationally recognized researchers having appropriate teaching experience to teach the full course program of Physical Chemistry. Willingness to cooperate with existing research groups at the institute (crystal structure, theoretical chemistry, spectroscopy and magnetochemistry, solid-state chemistry, quantum chemistry) and interest in interdisciplinary team work is expected. Candidates are asked to send their resume (curriculum vitae, teaching experience, list of publications etc) and reprints of five of their most important publications.

Application deadline is September 16, 1985. Submit your application and resume to: Dekan der Technisch-Naturwissenschaftlichen Fakultät der Technischen Universität Graz, Petersgasse 16, A 8010 Graz, Austria, where also additional information may be requested. (W1891)A

UNIVERSITY OF CALIFORNIA

DEPARTMENT OF PHYSICS

ENDOWED CHAIR PROFESSOR OF PHYSICS

The UCLA Physics Department has an open Endowed Chair position. An appointment will be considered in any field of experimental or theoretical physics. The successful candidate will have a regular University of California tenured faculty position; the endowment income will support the candidates' program.

The successful candidate will be expected to lead an internationally recognized research program, and to teach at the graduate and undergraduate level.

Applicants should send a curriculum vitae, a brief statement of past, present, and future research interests, and the names of 5-10 referees to C Kennel, Chair, Department of Physics, University of California, Los Angeles, CA 90024.

The department is especially interested in identifying women and minority candidates.

The University of California is an affirmative action/equal opportunity employer. (NW1435)A

UNIVERSITY OF SOUTHAMPTON

CHAIR OF OCEANOGRAPHY

Applications are invited for the Chair of Oceanography which will become vacant on the retirement of Professor H Charnock, FRS, on 30 September 1986. Applicants should have research interests in the physically-related marine sciences and the ability to foster work in a multi-disciplinary field.

Further details may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH, to whom applications (10 copies from persons in the UK) should be sent before 12 July 1985. (6626)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF PHYSIOLOGY

RESEARCH ASSISTANT

Applications are invited for the above post, tenable for up to three years, to work on a project concerned with thermal changes in the immersed human body. This phase of the work is a theoretical study and will involve mathematical modelling. Applicants should have, or expect to get, a good honours degree, ideally with some experience of modelling biological systems but ability and enthusiasm could offset lack of experience.

Salary within range £6,600 — £7,520 on the 1B Scale for Research and Analogous Staff, with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University Aberdeen, with whom applications (2 copies) should be lodged by 28 June 1985. (6622)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following position:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF DEVELOPMENTAL BIOLOGY

POSTDOCTORAL FELLOW - MOLECULAR ANALYSIS OF DEVELOPMENT PROJECT

A Postdoctoral Fellow is required in the Department of Developmental Biology for a project on genetic analysis of events in the cell cycle of Chlamydomonas. A background in genetics, biochemistry and ultrastructural analysis would be advantageous. The position will commence on 1 January 1986.

Further particulars can be obtained from Professor B Gunning, Head of Department (062) 49 2372, or from Dr P C L John (address until 31 July 1985, Department of Botany, Queen's University of Belfast, Belfast BT7 1NN, UK).

Closing date: 31 July 1985. Ref: BS 15/5/1.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow $A22,614 - $25,905 pa.

Appointment, unless otherwise stated, will be: Postdocotral Fellow normally two years, with the possibility of extension to maximum of three years.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote the advertisement reference when requesting further particulars, and when submitting applications, which should be sent to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. Further information also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The University is an equal opportunity employer. (W1904)A

POSTDOCTORAL POSITION

Is available immediately to study functional role of insulin in the brain at the cellular level with Drs. D.W. Clarke and M.K. Raizada. Experience in cell culture and biochemical techniques is a disirable. Experience with immunocyto-chemistry would be helpful. **Contact Dr. Mohan K Raizada, Dept of Physiology, J274, Univ of Fla Gvl, FL 32610 or telephone 904 392-3791.**

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER (85/17)

ASSISTANT SCIENTIFIC OFFICER (85/19)

SHORT TERM CONTRACTS (3 YEARS)

Applications are invited for 2 short term contracts (3 years) to examine gaseous forms of preslaughter anaesthesia in pigs and poultry. The project is aimed at resolving some of the humanitarian problems associated with the slaughtering of livestock

Salary SO/HSO £5,909 — £10,039. ASO £4,456 — £6,315.

Qualifications SO/HSO (Post 85/17) Degree in a Biological Science with relevant post-graduate research experience

ASO (Post 85/19) HNC in Biology.

Further particulars and an application form from the Personnel Officer at the above address.

The Agricultural and Food Research Council is an equal opportunities employer (6649)A

UNIVERSITY OF GLASGOW

DEPARTMENTS OF BIOCHEMISTRY AND PHARMACOLOGY

WELLCOME LECTURESHIP IN MOLECULAR PHARMACOLOGY

Applications are invited for a Wellcome Lectureship in Molecular Pharmacology to be held jointly in the Departments of Biochemistry and Pharmacology. The appointment will be for three years: it may be renewed for a further two years subject to satisfactory progress. Applicants should not be more than 35 years of age and persons having a permanent University post in the UK are ineligible.

The successful applicant will contribute to the teaching in both departments and in research will become part of an active interdepartmental group. The departments are in the process of appointing a 'New Blood' lecturer to the same group.

The salary will be within the range of £7,520 — £14,925 per annum of the Lecturer's scale, with placement according to age, qualifications and experience.

Those wishing to be considered should send eight copies of a statement of their qualifications and experience, including a list of publications and the names and addresses of not more than three persons to whom reference may be made, to Professor R M S Smellie, Department of Biochemistry, University of Glasgow, Glasgow, G12 8QQ, not later than 21st June, 1985, from whom further particulars may be obtained. The applications must be accompanied by a summary of not more than 500 words outlining the proposed research. (6666)A

HEINRICH-PETTE-INSTITUT FÜR EXPERIMENTELLE VIROLOGIE UND IMMUNOLOGIE
AN DER UNIVERSITÄT HAMBURG

Applications are invited for the Tenure Position of

HEAD OF DEPARTMENT OF MOLECULAR BIOLOGY

Candidates with extensive scientific experience are expected to lead a research group in the general field of molecular biology. Budget and tenure positions are available. The Heinrich-Pette-Institut is an independent research establishment, active in the fields virology, immunology, and cell biology. Administrative experience and willingness to participate in running affairs of the institute are required. Teaching at the University of Hamburg is on voluntary basis. The salary is according to BAT I and depends on age and family status.

Applications including curriculum vitae and list of publications should be sent: An das Direktorium, Heinrich-Pette-Institut, Martinistraße 52, D-2000 Hamburg 20, Federal Republic of Germany. Closing date 31 August 1985. (W1892)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
(University of London)
DEPARTMENT OF ENTOMOLOGY

LECTURER OR SENIOR LECTURER

Applications are invited from medical entomologists for a tenured post in the Entomology Department. Preference will be given to applicants combining tropical experience with an outstanding record in research, preferably in biochemistry, ecology, population dynamics, or insect behaviour, but experience in any field within entomology applied to human health will be considered.

The person appointed will be expected to develop active research programmes, with overseas connections, and the extensive facilities of the London School will be available for this.

Appointment will carry a salary in the range £8,753 to £18,938 (inclusive of London Weighting) on the Universities' Lecturer or Senior Lecturer scale according to age, qualifications and experience, with membership of USS.

Further information may be obtained from Professor A N Clements (01-636 8636 ext 348). Applications with full curriculum vitae and the names of three referees should be sent to the Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT.

Closing date: 5 July 1985 (6635)A

We are a major Italian pharmaceutical company with a growing interest in biotechnology.
We are looking for an experienced

BIOCHEMIST/ IMMUNOCHEMIST

For a newly created laboratory of biochemistry and immunology, located in the urban area of Milan, Italy.

Potential candidates should have a doctorate degree and post-doctoral training Previous experience in hybridoma technology for diagnostic purposes would be considered an advantage

We Offer:
- career opportunities based on performance;
- a competitive salary in accordance with experience and qualifications;
- a stimulating, dynamic work environment;
- assistance in relocation expenses

Candidates from EEC Countries are encouraged to apply.

MOLECULAR VIROLOGY UNIT

A molecular virology unit has been established to develop novel vectors for the expression of viral antigens in mammalian systems. This unit works in close collaboration with virologists and molecular biologists in this department and at the Beatson Institute.

Three positions, supported by the National Institutes of Health, are immediately available. Applications are invited for 2 post-doctoral fellows (salary range £8,450 to £10,720 per annum) and a research assistant (£6,600 per annum). The research assistant may apply to register for a higher degree.

The applicants should have experience in recombinant DNA technology and a background in virology would be an advantage. Applications should be sent to, and further particulars may be obtained from, Professor W F H Jarrett, FRS, University of Glasgow, Veterinary School, Bearsden, Glasgow, G61 1QH (telephone number 041-942-2301). (6658)A

BIOTECHNOLOGISTS!

What's going on in the world's fastest-growing scientific discipline?

To find out, send for a sample copy of BIO/TECHNOLOGY, the International Monthly for Biology and Industry, to

Felicity Parker, Macmillan Journals, Houndmills, Basingstoke, Hants. RG21 2XS, UK

or

Paul Siman, Bio/Technology, 65 Bleecker St., New York, NY 10012.

MOLECULAR BIOLOGIST

Applications for an assistant professorship are invited from individuals with major commitment toward research and whose interests are in the structure, regulation or expression of viral, or mammalian, genes. Expertise in genetic engineering of enzymology-protein chemistry, an asset. Knowledge of or readiness to learn French essential. Send applications to: Dr Pierre Bourgaux, Directeur, Département de Microbiologie, Faculté de Médecine, Centre Hospitalier Universitaire, Université de Sherbrooke, Sherbrooke, Québec, Canada J1H 5N4.

(NW1790)A

CHARING CROSS AND WESTMINSTER MEDICAL SCHOOL

(University of London)

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

required to investigate the organisation of Campylobacter DNA, particularly the structure and expression of toxin genes. Previous experience, preferably postdoctoral, in prokaryotic molecular genetics and recombinant DNA techniques is essential. Experience with expression vectors is desirable The successful applicant will join a group working on various applications of molecular biology to clinical problems.

The post is available immediately for a fixed term period of up to three years. Salary will be on Scale 1A for Research and Analogous staff, (£7,520 — £12,150 pa) at a point appropriate to age and experience plus £1,233 pa London Allowance.

For further information concerning the project or the department, telephone Dr L Archard, 01-741 1858.

Applications on forms obtainable from The Secretary, Charing Cross and Westminster Medical School, The Reynolds Building, St Dunstan's Road, London, W6 8RP, to be submitted within three weeks of the appearance of this advertisement.

(6625)A

UNIVERSITY OF LONDON

RANK CHAIR OF PHYSIOLOGICAL BIOCHEMISTRY TENABLE AT IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

The Senate invite applications for the above Chair, tenable in the Department of Biochemistry at Imperial College of Science and Technology.

Candidates should have demonstrated an interest in cellular biochemistry and/or control of integrated physiological processes. They should have significant research accomplishments and an interest in the teaching of these aspects of biochemistry in advanced undergraduate courses.

Applications (10 copies) must be received not later than 15 July 1985 by the Academic Registrar (N.), University of London, Malet Street, London WC1E 8HU, from whom further particulars should first be obtained

(6631)A

NEUROENDOCRINE RESEARCH GROUP

DEPARTMENT OF ANATOMY

UNIVERSITY OF CAMBRIDGE

We are seeking a postdoctoral physiological psychologist, or relevantly qualified zoologist or clinical graduate to join a multidisciplinary research tea investigating the neuroendocrine basis of social behaviour and anxiety in an experimental setting. The position is funded by the MRC and available immediately; the initial appointment is for 1 year, renewable for up to 5 years in total

Please send applications (including CV) to Mrs J Penton, Department of Anatomy, University of Cambridge, Downing Street, Cambridge CB2 3DY by July 1st, and arrange for references to be sent direct from 2 referees.

(6686)A

THE ANIMAL VIRUS RESEARCH INSTITUTE

POST-DOCTORAL MOLECULAR BIOLOGIST

Applications are invited for a 3 year appointment to work on analysis of the genome structure of classical swine fever (hog cholera) virus and its relationship to bovine virus diarrhoea. The work will involve molecular cloning of the genome RNA and nucleotide sequence determination. The successful applicant will work with Dr Charles Penn in the Division of Molecular Biology He/she should have a degree in biochemistry, microbiology or a related subject and a PhD. Experience in gene cloning would be an advantage.

The salary will be in the scale of £7,435 - £10,039 (Higher Scientific Officer grade) pay award pending. Sick leave and non-contributory superannuation schemes, 22 days annual leave. Accomodation may be available. The AVRI is an equal opportunity employer.

Application to include a curriculum vitae and the names of two referees should be sent as soon as possible to the Secretary, Animal Virus Research Institute, Ash Road, Pirbright, Woking Surrey GU24 0NF. Tel: 0483 232441. (6640)A

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF BIOCHEMISTRY

TEMPORARY LECTURESHIP

A vacancy exists for a Temporary Lecturer as a result of Dr J R Burton being awarded a five-year Research Fellowship by the Lister Institute. Candidates with research interests in any area of Biochemistry are eligible to apply for preference may be given to those with experience of recombinant-DNA technology or immunology. It is expected that the successful candidates will be appointed for a period of three years with the possibility of extension for a further two years.

Salary within the range £7,520 — £11,675 on the non-clinical lecturers salary scale.

Applications including the names of three referees should be sent to the Personnel Department (Academic Staffing), the University, Sheffield S10 2TN by 14 June 85 from whom further particulars are available. Quote ref: R275/G (6617)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

RESEARCH ASSISTANT

Applications are invited for the above post, tenable immediately for up to two years, to work on the isolation of cNDA clones for the structural glycoprotein present in human aorta. A range of microbiological, immunological and gene cloning techniques will be involved. Applicants should have an honours degree in an appropriate discipline.

The appointment is funded by the Maitland Ramsay Trust. Starting salary within the range £6,600 to £7,980 per annum (under review) according to age and experience, on the 1B scale, plus USS.

Further information can be obtained by writing or by telephone from professor Serafini-Fracassini (tel 0334-76161, ext 275).

Applications (2 copies preferably in typescript) enclosing a full curriculum vitae and the names of 2 referees should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ to arrive not later than 20 June 1985.

(6661)A

UNIVERSITY OF OXFORD

DEPARTMENT OF NUCLEAR PHYSICS

APPOINTMENT OF RESEARCH OFFICER

The department will shortly appoint a Research Officer in Particle Physics. Whilst mainly a research appointment, the appointee will be required to undertake seventy-two hours a year of laboratory demonstrating and he/she will be encouraged to give graduate lectures. The research programme of the experimental particle physics group includes the Soudan II search for proton decay, a major contribution to the DELPHI detector for LEP (CERN), preparation for an experiment at HERA (DESY), and development of an indium detector for solar neutrinos.

The appointment will be for three years with possible extension to five years. Salary will be on the Lecture scale £7,520 - £15,930 (under review).

Applications with the names and addresses of two referees should be sent to Mr M S Gautrey, Department of Nuclear Physics, Keble Road, Oxford from whom further particulars may be obtained. The closing date is September 5th 1985.

(6676)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY DIVISION OF IMMUNOLOGY

SCIENTIST

A Scientist with a post-graduate qualification in Biochemistry or Organic Chemistry is required to join in a project investigating the development of immunoassay systems using red cell-labelled antibodies. Experience in protein chemistry or immuno-chemistry desirable The appointment is for two years in the first instance, possibilities of an extension.

Enquiries to Professor R R A Coombs, Division of Immunology, New Adenbrooke's Hospital, Hills Road, Cambridge. Tel Cambridge 0223 245171 ext 336. Age up to 30

Salary range: University scales age related.

Formal applications together with curriculm vitae and the names and addresses of two referees to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. (6667)A

UNIVERSITY OF LEICESTER/DARESBURY LABORATORY

POST-DOCTORAL RESEARCH ASSOCIATE IN EXPERIMENTAL X-RAY DIFFRACTION AT HIGH PRESSURES

Applications are invited for the above post, funded by SERC, tenable from 1st October 1985, or as soon as possible thereafter, for up to three years.

The successful candidate will be expected to pursue research at the Synchrotron Radiation Source at Daresbury into structural changes in solids at very high pressures, on the newly commissioned Power Diffraction Station on the Wiggler beam line. The project involves application of novel high-resolution powder diffraction techniques to materials at very high pressures, and is backed by a major theoretical programme of molecular dynamics simulations.

Applicants should hold a PhD in experimental science. Experience with X-ray or neutron crystallography, and computing would be an advantage. The starting salary will be in the range £7,520 to £8,450 according to age and experience.

Applications, together with a full curriculum vitae and the names of two referees to Dr D M Adams, Department of Chemistry, University of Leicester, Leicester LE1 7RH by 15th July 1985. (6682)A

SANDWELL HEALTH AUTHORITY

The Midland Centre for Neurosurgery and Neurology

DEPARTMENT OF PATHOLOGY

ELECTRON MICROSCOPIST in charge of Section

(Basic/Senior Science Graduate)

required on a Locum basis (available grading up to Senior as defined by Whitley Council PTA regulations). Well housed department with two other staff, two Siemens microscopes, several ultramicrotomes. Successful applicant will be required to continue and develop service in Muscle, Central and Periperal Nervous System Pathology, to Hospital and Region. Collaboration with current research projects will be expected and there is an excellent opportunity to develop a personal research programme on the readily available material.

Intending applicants are welcome to visit by appointment with Dr M V Salmon (Neuropathologist) - 021-558 3232 ext 314.

Job description and application form from the Administrator, Midland Centre for Neurosurgery and Neurology, Holly Lane, Smethwick, Warley, West Midlands B67 7JX. Tel: 021-558 3232 ext 251. (6677)A

Cell Biologist/Biochemist/ Neurobiologist

Postdoctoral research position is immediately available for PhD with experience in cell biology, biochemistry, or neurobiology to investigate hereditary neuromuscular disorders. Initial research will focus on mechanisms of regulation of cell growth and the developmental expression of surface proteins in nerve, muscle, and related tissues. Applicants should have a PhD and experience in: cell biology and biochemistry, culture of nerve, muscle and fibroblasts; immunological methods for the study of cell proteins. Extensive possibilities exist for collaboration with expert neuromuscular morphologists and with active molecular genetics/recombinant DNA laboratory. Excellent support; salary commensurate with experience. Direct inquiries to Dr. Robert H Brown, Jr , Day Neuromuscular Research Center, Massachusetts General Hospital Warren 370/374, Boston, MA 02114. (NW1792)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

ENDOCYTOSIS

A post-doctoral research assistant is required to work on a cell-free assay for studying the pathway of adsorptive endocytosis. The aim is to understand the molecular basis of this process. Preference will be given to candidates with training in membrane biochemistry and/or enzymology.

This project is funded by the MRC and the position is for three years commencing 1st January 1986. The salary will be in the range £7,520-£12,150 per annum.

Applications, including a curriculum vitae, research summary and the names and addresses of three referees, should be sent to the Personnel Officer, The University, Dundee, DD1 4HN, Scotland as soon as possible. Informal enquiries concerning this project should be addressed to Professor Graham Warren, who is presently at the European Molecular Biology Laboratory, Postfach 10 2209, 6900 Heidelberg, West Germany. Tele phone number 010 49 6221 387324. Please quote Ref EST/66/85J. (6466)A

RESEARCH ASSOCIATE POSITION

Opportunity exists to work on a project concerned with the biochemical mechanisms of hormone (insulin) action to control phosphorylation and redox state Applications are invited from qualified candidates with a Ph D or M.D. degree. Submit a resume of research interests, curriculum vitae and three letters of recommendation to Dr Joseph Larner, Department of Pharmacology, Box 448, University of Virginia School of Medicine, Charlottesville, Virginia 22908. An affirmative Action/Equal Opportunity Employer (NW1812)A

AGROGEN BIOTECHNOLOGIES SENIOR SCIENTISTS — PLANT TISSUE CULTURE

Agrogen Biotechnologies Inc , a Vancouver, BC based Canadian company interested in plant tissue culture, micropropagation of woody ornamentals and forest tree species and related biotechnologies is seeking Senior Scientists in plant tissue culture to provide project leadership and research support to its micropropagation program.

The positions require a PhD with a strong background in plant physiology, cell biology, genetics or biochemistry with several years research experience in plant tissue culture. Agrogen offers the opportunity to join an energetic interdisciplinary research team, excellent research facilities, competitive salary and fringe benefits.

Please forward your curriculum vitae and other pertinent information in confidence to: Dr. D. Paul Webb, Director of Research, Agrogen Biotechnologies, Inc. 1710-1066 West Hastings Street, Vancouver, BC V6E 3X2. (NW1793)A

THE UNITED MEDICAL AND DENTAL SCHOOLS

ST THOMAS'S CAMPUS

RESEARCH ASSISTANT

(post-doctoral)

required to work on project on the role of Coxsackie-B Viruses in the pathogenesis of insulin-dependent diabetes mellitus (type 1).

Sound virological experience essential; experience with such techniques as ELISA, monoclonal antibody production and PAGE an advantage. Funding is being sought for one year appointment from 1 September 1985 in the first instance Salary not less than £7,520 plus £1,233 LWA pa (grant application pending).

For further information, contact Professor J E Banatvala, Dept of Virology, tel: 01 928 9292 ext 2405.

Applications giving full cv and names and addresses of 2 referees to Staffing Officer, Dean's Office, St Thomas's Hospital Medical School, London SE1 7EH by 13 June 1985. (6664)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF GEOLOGY

POST-DOCTORAL/ POST-GRADUATE RESEARCH ASSISTANT IN SEISMOLOGICAL COMPUTING

To work on the acquisition, digitisation processing and interpretation of the data from an international seismic refraction experiment to be carried out in Kenya in August 1985 The data processing will require the development, maintenance and operation of Fortran 77 programmes on VAX 11/70-8600 system. The anpointment will be for two years from July 1985 with a salary of £6,600 — £7,055

Applications, including a CV and the names of two referees, should be sent by June 7 to Dr M A Khan, Department of Geology, The University, Leicester LE1 7RH from whom further particulars may be obtained. (6641)A

UNIVERSITY COLLEGE LONDON

RESEARCH TECHNICIAN

Grade 4

Cell Biology

Applications are invited for the above post to assist in the development of a new project on the intracellular transport of membrane proteins, funded for 3 years by the MRC.

The person selected to join our small friendly group will have an interest in research and be qualified to at least HNC standard. Experience with tissue culture, cell fractionation or protein purification would be an advantage.

Salary £6,106 — £6,837 + £1,250 London Weighting.

Applications, including CV and the names of 2 referees should be sent to Personnel Officer (Technical Staff GE6), University College London, Gower Street, London WC1E 6BT. (6651)A

ROYAL HOLLOWAY AND BEDFORD COLLEGES

RESEARCH ASSISTANT

Applications are invited from Physicists, Engineers or Applied Mathematicians, to join a team engaged in a range of projects on fundamental aspects of Electromagnetic Antennas for Millimetric Wavelengths This project involves both theoretical work (using analytical and computational techniques) and supporting experimental studies in one or more of the following areas:-

(1) Electromagnetic Theory
(2) Numerical Control Engineering
(3) Applied Optics

Candidates should have an aptitude for research and a good degree or a postgraduate qualification in a relevant subject. Salary scale £9,863 — £11,093 (under review).

Applications (2 copies) with curriculum vitae and names and addresses of 2 referees should be sent immediately to the Personnel Officer, Royal Holloway and Bedford Colleges, Egham Hill, Egham, Surrey TW20 0EX. (6648)A

FACULTY POSITION

The Psychology Department of the Massachusetts Institute of Technology announces the opening of a faculty tenure-track position in neuroscience. Applicants with a PhD or equivalent degree are sought with training and research background in mammalian brain-morphology and function

Interested applicants should send a letter of inquiry with curriculum vitae and three references by July 31, 1985, to:

Dr. Peter H. Schiller
Psychology Department
Search Committee
Massachusetts Institute of Technology, E25-634
77 Massachusetts Ave.
Cambridge, MA 02139.

Qualified minorities and women are encouraged to apply. MIT is an affirmative action/equal opportunity employer. (NW1791)A

MIT

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF PHYSIOLOGY

WELLCOME LECTURESHIP

Applications for the above post are invited from candidates in the field of neuroscience with expertise and interest in pursuing research involving the use of an in-vitro brain slice. Candidates wishing to visit the department or make provisional enquiries should contact Professor A M Sillito (0222)-44211 ext 2062.

Candidates should be less than 35 years old and must not currently hold a permanent university appointment. The post is tenable for five years (subject to a review after three years) and should commence on the 1st October 1985, although this date could be negotiated for a suitably qualified date. Appointment will be made at the appropriate point on the lecturer scale (scale is £7,520-£14,925).

Applications (three copies) with curriculum vitae, 500 word synopsis of the proposed research and the names and addresses of three referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P O Box 78, Cardiff CF1 1XL from whom further particulars may be obtained. Closing date 24th June 1985 Reference 2967 (6678)A

UNIVERSITY OF DUBLIN
Trinity College

TEMPORARY LECTURER IN ZOOLOGY

Applications are invited for the above post in the Department of Zoology at Trinity College, Dublin. The appointment will be tenable from 1st October, 1985 for one year, and may be renewed for a further year. Preference will be given to candidates having interests in Invertebrate Reproduction

Salary IR £9,302 per annum

Application forms and further particulars relating to this appointment may be obtained from.

Establishment Officer
Staff Office
Trinity College, Dublin 2
Tel 772941 Ext 1775

to whom completed application forms should be returned by **not later than Tuesday, 11th June, 1985** (6638)A

UNIVERSITY OF ZUERICH
DEPARTMENT OF PHYSIOLOGY
A MOLECULAR BIOLOGIST

is required for a three year postdoctoral position, to work on the regulation of mRNA by oxygen availability in cultured kidney cells Applicants should have PhD or equivalent in Biochemistry/molecular Biology and a minimum of two years of postdoctoral experience in these areas Knowledge in cell culture techniques would be an advantage Salalry in range sFr 47 000-60 000/yr, depending on experience and qualification. The position is available now, starting date to be agreed

Application with the names and addresses of two referees should be sent to Professor C. Bauer, Dept. of Physiology, University of Zuerich, Winterthurerstr 190, 8057 Zuerich, Switzerland. (W1894)A

PROFESSOR & HEAD
Biological Sciences
Carnegie-Mellon University

The Department of Biological Sciences invites applications from qualified individuals to serve as Professor and Chairperson We seek an individual with an established reputation in any field of biological research and an ability to provide leadership in the continuing growth of this department We expect to appoint the successful candidate by 30 June 1986 or before

Applications or inquiries should be sent to Professor W R McClure, Chairman, Search Committee, Carnegie-Mellon University, 4400 Fifth Ave , Pittsburgh, PA 15213
Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer.
(NW1765)A

CONFERENCES and COURSES

UNIVERSITY COLLEGE, LONDON:
SCHOOL OF MEDICINE

PART TIME COURSE IN TOXICOLOGY

A course in toxicology consisting of lectures and practical classes will be given weekly for 30 weeks, on Wednesdays at 15:45-19 00 hrs, starting on 2nd October 1985

A broad treatment of topics in toxicology will be presented, including basic histopathology, biochemical and genetic aspects and methodology. Regulatory aspects of toxicology will also be discussed The course is intended (1) for graduates with some experience in a relevant field; (2) for postdoctoral and other scientists wishing to broaden their knowledge of toxicology

The fee for the 30 week course is £600. Numbers will be restricted to a maximum of 25 participants Some assisted places where all or part of the course fees are waived are available to suitable applicants whose fees are not paid by their employer (e g persons working in Universities or similar institutions and holding non-tenured posts) Further details and application forms may be obtained from: —

Dr. I.C. Shaw
Toxicology Laboratory
Department of Clinical Pharmacology
University College London
5 University Street
London WC1E 6JJ, England
(01) 388-2411 Ext 212

Closing date for applications — 1st July 1985 (6656)C

Royal Postgraduate Medical School
(University of London)

A specialist scheme of study for graduates in medicine and biology leading to the award of:

DIPLOMA in ENDOCRINOLOGY

This is a one academic year, full-time, intensive laboratory-based training course open to graduates in medicine and biology who wish to develop skills in modern endocrinological investigative methods The selected applicants, who must be experienced in light or electron microscopical morphology, biochemistry or a related discipline, will undertake a series of research projects during their training period in recognised laboratories within this Medical School Award of the Diploma will depend on successful completion of an examination or by thesis

Further details and application forms may be obtained by writing to:

The School Office, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS

Completed application forms must be received before 31 July 1985 for registration on the 1985-86 Diploma course (6681)C

GRANTS and SCHOLARSHIPS

Research Award in Immunoregulation

Centocor, Inc., will award a $10,000 unrestricted research grant for the most outstanding human Interferon-Gamma scientific paper published (or accepted for publication) between 1/1/85 and 6/30/86.

For details, write to Centocor customer service.

FELLOWSHIPS

THE UNIVERSITY OF SHEFFIELD

Faculty of Medicine

J G GRAVES MEDICAL RESEARCH FELLOWSHIP

Applications are invited for the above Fellowship tenable for a period of three years from 1 October 1985. The Fellow will be required to undertake full-time medical research in one of the medical or dental departments or hospital. Initial salary according to qualifications and experience within the range £7,520 — £8,920 a year, a higher salary may be offered to a candidate with appropriate experience and seniority. Additional funds may be available for the Provsision of laboratory assistance and materials.

Further particulars from the Personnel Department (Academic Staffing), the University, Sheffield S1Q 2TN to whom applications (10 copies), including the names and addresses of three referees, (indicating the line of research proposed), should be made by 17 June 1985. Quote refs R269/G. (6665)E

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

Supported by the British Gas Corporation. The work will be concerned with "Development of Membranes with Improved Selectivity" and will be directed mainly towards synthesis of novel polymers suitable for fabrication into membranes showing improved selectivity in gaseous diffusion processes combined with high stability at elevated temperatures.

The post will initially be for one year with a salary of up to £8,920 per annum depending on age, qualifications and experience. Superannuation is under USS conditions.

Applications are invited in the form of a curriculum vitae (3 copies) including the names and addresses of two referees, and should be sent to the Personnel Office (JLG), University of Surrey, Guildford, Surrey GU2 5XH as soon as possible, quoting reference 375. (6646)E

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Cell Culture of Marine Algae

Applications are invited for a Post-Doctoral Research Fellowship funded by the University of Aberdeen to work with Drs S B Wilson, F B Williamson and W F Long. The project will involve the development of continuous cultures of marine red algal cells primarily to produce materials with commerical value.

The post has initially been funded for one year but scope exists to obtain further financial support giving an appointee with flair and imagination a chance to share in the longer term future of this exciting new field. Applicants should preferably have a PhD and some experience in cell culture.

Salary on Range IA Scale for Research and Analogous Staff up to £8,920 per annum, with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by 30 June 1985. (6668)E

POSTDOCTORAL FELLOWSHIP

In Molecular Biology/Biochemistry Position available Sept. 1, 1985 in Department of Microbiology at SUNY Stony Brook to study adeno-associated virus genetics, vector construction immunology or DNA replication. Send CV and references to Dr. Nicholas Muzyczka, University of Florida, College of Medicine, Box J-266 JHMHC, Gainesville, Florida 32610. (NW1797)E

POSTDOCTORAL FELLOWSHIP POSITIONS

Molecular Biology

Well-established cardiovascular research laboratory studying the molecular biology of lipoproteins and receptors is seeking molecular biologists with experience in cloning and DNA sequencing

Candidates with a Ph.D. in molecular biology or biochemistry are eligible

Send curriculum vitae and three letters of reference to: Personnel, c/o Dr. Brian McCarthy, The Gladstone Foundation Laboratories for Cardiovascular Disease, University of California, San Francisco, P.O. Box 40608, San Francisco, CA 94140-0608.

(NW1803)E

POSTDOCTORAL FELLOWSHIPS

California Biotechnology Inc. invites applications from recently qualified Ph.D.'s to join its postdoctoral research program. CBI is an established biotechnology company located in the Palo Alto area forty miles south of San Francisco. The company, which has about eighty scientific employees, is dedicated to applying the techniques of molecular biology, protein chemistry and cell biology to develop novel human and veterinary pharmaceuticals. It currently has major research programs in hypertension, atherosclerosis, inflammation, lung disease, reproductive biology, growth factors and polypeptide hormones. Recent graduates, who have experience in areas such as recombinant DNA technology, protein and peptide chemistry, cell biology and pharmacology, would join established research teams in one of the above areas. The postdoctoral fellowship would for a minimum of two years.

(NW1800)E

Please send applications, including a complete curriculum vitae to:

CBI

Dr. John Shine
Director of Research
California Biotechnology Inc.

Mountain View, CA 94043

ESF PROGRAMME OF RESEARCH FELLOWSHIPS IN TOXICOLOGY

Short-term (up to 6 months) and Long-term (6-12 months) Research Fellowships (deadline: 30 September 1985) and Short-term (up to 1 month) Visiting Fellowships (no deadline) are offered to scientists working in European countries. No formal condition of age, level or field of training, provided the project contributes to furthering research in TOXICOLOGY in Europe. Information and application forms can be obtained from: Dr John Smith, European Science Foundation, 1, quai Lezay-Marnésia, F-67000 STRASBOURG, France; tel (88) 35 30 63; telex 890440. (W1890)E

EMBO
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
Autumn 1985 — Awards
Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R. Germany.

STUDENTSHIPS

THE POLYTECHNIC OF CENTRAL LONDON

Faculty of Engineering & Science

RESEARCH POSTS IN THE SCHOOL OF BIOTECHNOLOGY

A. GENERAL AND MOLECULAR GENETICS OF FILAMENTOUS MICROORGANISMS

Post 1. SERC Research Studentship

Post 2 Research Assistantship

B. MICROBIAL PHYSIOLOGY/ BIOCHEMISTRY

Post. 3 SERC Biotechnology Research Studentship for a project entitled "Beta-lactum biosynthesis in free and immobilized Streptomycetes.

Post 4. Research Assistantship — candidates should have an interest in analytical biochemistry and particularly HPLC techniques.

Posts 1, 2 and 3 are tenable for three years from 1st October 1985. Applicants should hold or expect to gain a first or upper second class honours degree in a relevant discipline. The successful candidates will be expected to register for a PhD Degree.

Post 4 is available immediately or as soon as possible and applicants should hold or expect to hold a degree in an appropriate subject and is tenable for a minimum of three years. For suitably qualified and motivated candidates there may be an opportunity to register for an M Phil degree.

Salaries for posts 1 and 3 will be according to SERC current regulations. Salaries for posts 2 and 4 will be according to University Research Assistant Scales since the project "Extended Use of Biocatalysts" is undertaken by PCL jointly with University of Kent at Canterbury and University College London under the auspices of the Institute for Biotechnological Studies. The programme is financially supported by the Department of Trade and Industry and seven major industries.

Please send a curriculum vitae and the names of two referees to the Personnel Officer, The Polytechnic of Central London, 309 Regent Street, London W1R 8AL, as soon as possible.

PCL is an equal opportunities employer. (6615)F

OXFORD UNIVERSITY

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF NEUROLOGY

POSTGRADUATE RESEARCH STUDENTSHIP

Applications are invited for a research studentship tenable in the Muscular Dystrophy Group Research Laboratories, Newcastle General Hospital. The successful applicant will read for the degree of PhD Two topics are available. (i) intermediary metabolism in skeletal muscle and the origin of metabolic myopathies; (ii) the use of cytochemical techniques to study the molecular differentiation of the muscle cell surface during development and regeneration of the neuromuscular junction

Candidates should be qualified in an appropriate discipline (biochemistry, physiology, etc) and should possess or expect to obtain a First Class or Upper Second Class Honours degree.

Application should be made within two weeks of the appearance of this advertisement in the form of a curriculum vitae, and candidates should include the names of two academic referees The project for which application is being made should also be identified. All correspondence should be sent to Professor J B Harris, Muscular Dystrophy Group Research Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne NE4 6BE, from whom further information may be obtained. (6643)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GEOGRAPHY

POSTGRADUATE STUDENTSHIP

Applications are invited for a postgraduate studentship to work with Dr Ann Henderson-Sellers on Synthesis of cloud climatologies.

This project builds on previous work in the department and is a contributory part of the International Satellite Cloud Climatology Project (ISCCP). The student will be expected to have, or aquire, a sound knowledge of meteorology. Much of the data analysis is computer-based so that previous experience of computer programming would be useful. The project is funded by a grant from the US Air Force and will involve the student collaborative work with US and European scientists. It is anticipated that applicants will hold, or hope to gain, at least an upper second class honours degreem in physics, mathematics or physical geography or a similar science subject.

Applications, together with the names of two referees should be received not later than 20 June, 1985, by The Registrar, The University, PO Box 147, Liverpool L69 3BX Quote ref RV/291/N. (6620)F

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMISTRY

Applications are invited from Chemistry graduates, or those about to graduate for the following research studentships which will become available as from 1st October, 1985.

(1) A CASE studentship in conjunction with ICI Pharmaceuticals to study A Thermodynamically-Based Scale of Hydrogen Bond Basicities. (Dr M H Abraham).

(2) A CASE studentship in conjunction with the Imperial Cancer Research Fund to study Mechanisms of Aromatic Hydroxylations. (Dr J R Jones).

(3) A Ministry of Defence sponsored studentship to study Aromatic Amine Cure of Epoxy Resins. (Drs G J Buist and J R Jones).

(4) A CASE studentship in conjunction with ICI to study The Synthesis of Polysulphones from Arylsulphonic Acids and PCl_5. (Professor J B Rose).

Interested persons should send their curriculum vitae and the names and addresses of two referees to Dr J R Jones, Chemistry Department, University of Surrey, Guildford GU2 5XH, as soon as possible (6647)F

GEORGE HENRY LEWES STUDENTSHIP

Applications are invited for this Studentship to pursue original investigations in Physiology. Appointment may be from 1 October 1985 for one year with a possibility of renewal for up to two further years. The award will provide an annual maintenance grant in line with the maintenance element of a Research Council research studentship; and the trustees will pay University and College fees for the holder at the rates charged to science research students from the UK.

Candidates should by 28 June 1985 send (a) a statement of their qualifications and their need for pecuniary help, (b) the subject of their proposed research, and (c) the names and addresses of two referees, to Professor R D Keynes, Physiological Laboratory, Downing Street, Cambridge CB2 3EG, from whom further particulars may be obtained. (6639)F

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF MICROBIOLOGY

RESEARCH STUDENTSHIP IN MOLECULAR BIOLOGY

Applications are invited from persons possessing or expecting to obtain at least an Upper Second Class Honours degree in a Biological Science.

The successful applicant will join a group involved in the study of microbial pathogenesis using molecular genetic techniques.

Further details may be obtained by contacting Dr I N Clarke on Southampton 0703 777222 ext 3853. Please quote reference number AJS/85/37/N. (6671)F

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

SERC RESEARCH STUDENTSHIP

Photosensitization of Tumours

Applications are invited for the above studentship, tenable from October 1985, to study fundamental biochemical aspects of photochemotherapy, a new approach to cancer treatment, involving photosensitization of tumours by porphyrin-containing drugs.

Candidates should have, or expect to obtain, a good Honours degree in Biochemistry or an appropriate related discipline.

Further information may be obtained from Dr S B Brown, Department of Biochemistry, University of Leeds, LS2 9JT (0532 431751 ext 7500), to whom applications (including the names of two referees) should be sent. (6663)F

UNIVERSITY OF SHEFFIELD

DEPARTMENTS OF BIOCHEMISTRY AND MICROBIOLOGY

SERC EARMARKED STUDENTSHIP FOR PROTEIN ENGINEERING

A studentship is available for three years from October 1985 to work for a PhD on in vitro mutagenesis of a bacterial glutamate dehydrogenase. The student would join an interdisciplinary team headed by Professor J R Guest (DNA manipulation), Dr P C Engel (enzymology) and Dr D W Rice (crystallography) but would primarily be involved in the DNA aspects of the project.

Applicants should have or expect to obtain a First or Upper, Second Class Honours Degree in Biochemistry or Microbiology.

Applicants naming two referees should be sent to Dr P C Engel, Department of Biochemistry, University of Sheffield, Western Bank, Sheffield S10 2TN by 14 June 1985. Quote ref: R247/G. (6616)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ZOOLOGY AND COMPARATIVE ANATOMY

SERC CASE STUDENTSHIP

Applications are invited for a SERC CASE Studentship to work in collaboration with Dr F Y Liew (Wellcome Research Laboratories, Beckenham) on the protection potential of T cell responses in mice to genetically engineered specific HSV glycoprotein peptide fragments.

Applicants should have at least 2.1 Honours degree in Biochemistry, Biology, Immunology or Genetics.

Applications, together with the names of 2 referees should be made by 30 June 1985 to Dr W L Chan, Dept of Zoology and Comparative Anatomy, University College London, Gower Street, London WC1E 6BT Tel: (01) 387 7050 ext 428 (6675)F

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY

SERC STUDENTSHIP

Applications are invited for a 3 year studentship to work on the structure of squid rhodopsin and its role in activation of the photoreceptor enzyme cascade, using electron microscope image analysis and biochemical methods. Applicants should have, or expect to obtain, a good Honours degree in Biophysics, Biochemistry or related subjects.

Applications with a curriculum vitae and names of 2 referees should be sent as soon as possible to Dr H R Saibil, Department of Zoology, South Parks Road, Oxford OX1 3PS, to whom further enquiries may be made (Tel (0865) 56789 ext 317). (6657)F

UNIVERSITY OF READING

SUB DEPARTMENT OF HORTICULTURE

SERC CASE STUDENTSHIP IN PLANT PHYSIOLOGY

Applicants are invited for a CASE studentship tenable from 1 October 1985 to study genetic and environmental effects on the physiology and biochemistry of pod development in cocoa, in collaboration with Cadbury Schweppes plc.

Candidates should possess, or expect to obtain, a first or upper second class honours degree in Plant Sciences, Biochemistry or a closely related subject.

Further details may be obtained from Dr P Hadley, Sub Department of Horticulture, University of Reading, Earley Gate, Reading RG6 2AU. Applicants should send a curriculum vitae with the names of two referees not later than 10 June 1985 (6618)F

IMPERIAL COLLEGE (University of London)

CENTRE FOR BIOTECHNOLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited from candidates, preferably with a background in molecular biology, who hold, or expect to be awarded, at least two: one honours in biochemistry or biology for SERC research studentship. The award is for three years commencing October 1985. The project will involve the supression of gene expression in plants by anti-message RNA.

Informal inquiries may be made to Doctor Conrad Lichtenstein, Tel: (01) 589 5111 Ext 4112/7094.

Applications (cv and two academic referees) should be sent to me no later than June 30th 1985.

To: Centre for Biotechnology, Imperial College, London SW7 2AZ. (6690)F

UNIVERSITY OF ABERDEEN

DEPARTMENTS OF CHEMICAL PATHOLOGY AND THERAPEUTICS AND CLINICAL PHARMACOLOGY

POSTGRADUATE STUDENTSHIP

Applications are invited from graduates to work on a research project involving the use of isolated renal proximal tubular cells to investigate mechanisms of drug-induced nephrotoxicity. Candidates should have a good Honours degree in Biochemistry, Pharmacology or a related subject.

The studentship is initially for one year and the student will be registered for an MSc. Applicants, with a full curriculum vitae and the names of two academic referees, should be sent to Dr P Whiting, Department of Chemical Pathology, University Medical Buildings, Foresthill, Aberdeen AB9 2ZD as soon as possible. Further details are avalable from Dr Whiting (telephone 0224-681818, ext 2822) or Dr G Hawksworth (ext 2463). (6685)F

UNIVERSITY OF WARWICK

DEPARTMENT OF CHEMISTRY

SERC CASE AWARD

Solution Chemistry of Technetium : Redox and Extraction Properties

Applications are invited from graduates or those expecting to graduate this Summer with at least a class II-1 honours degree in chemistry, for this studentship. The project, carried out in collaboration with British Nuclear Fuels plc, will be concerned with kinetics of chain reaction of TcO_4^- with hydrazine and with the co-extraction of Tc with UO_2^{2+} ion. Normal SERC rates will be supplemented by £600 pa.

Further details may be obtained on application to the Personnel Office, University of Warwick, Coventry CV4 7AL. Please quote Ref No 42/A/85/O. Closing date for applications 21st June 1985. (6672)F

UNIVERSITY OF GLASGOW

BIOTECHNOLOGY UNIT

SERC CASE STUDENTSHIP — ICI

To clone and study expression of resistance and production genes from Streptomyces for an antibiotic of interest to ICI. The project is supervised jointly by Dr I S Hunter (Glasgow) and Dr P Groves (ICI, Corporate Lab, Runcorn).

Applicants should have, or expect to obtain, a first or upper second class honours degree in a related biological science. Interviews will be conducted towards the end of June.

Applications (CV and names of two referees) should be sent to Dr I S Hunter, Institute of Genetics, Church Street, Glasgow G11 5JS, before June 13th, 1985. (6596)P

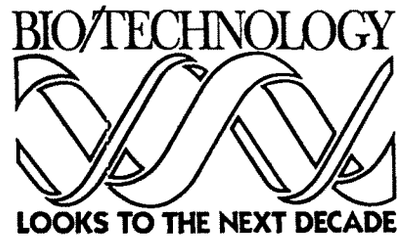
AWARDS

ROSENSTIEL AWARD IN OCEANOGRAPHIC SCIENCE

Nominations are invited for the 1985 Rosenstiel Award in Oceanographic Science.

This award, administered on behalf of the Rosenstiel Foundation by the Rosenstiel School of Marine and Atmospheric (RSMAS) at the University of Miami recognizes outstanding contributions to marine science, including oceanographically relevant aspects of atmospheric science, and fundamental developments in ocean engineering. The award consists of a cash prize, currently $5,000, and a medal. The recipient of the award will be invited to spend a week at RSMAS for discussions with faculty and students. The award will be presented at that time.

To accumulate the multidisciplinary value of oceanographic science, the award recognizes, on a rotating basis, achievements in four broad disciplinary areas. In 1985 the emphasized discipline will be physical oceanography and air-sea interaction The achievements recognized may consist of contributions towards the development of ocean science in general, or of more focussed individual research of recognized impact on our understanding of the marine environment.



Nominations for the 1985 award for outstanding achievement in physical oceanography or air-sea interaction should be directed to Dean Alan Berman, Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149-1098, before August 15, 1985 Nominations should include a brief justification together with relevant reference The selection panel would especially welcome nominations of outstanding younger scientists, whose early contributions suggest a continuing role of leadership in the field. (NW1796)N

CONFERENCES and COURSES

ATTENTION SCIENTISTS AND RESEARCHERS

Posters are now being accepted for BIO/TECHNOLOGY's premier conference

BIO/TECHNOLOGY

LOOKS TO THE NEXT DECADE

January 20-22, 1986, Clarion Hotel, New Orleans

You are invited to submit abstracts of work with commercial implications to:

Research Editor
BIO/TECHNOLOGY Conference
65 Bleecker Street, New York, NY 10012

Ideas suitable for support from corporate or venture funding are particularly welcome.

Conference Themes:

Day 1: The Molecular Biology of Plants & Animals
Day 2: Commercial Production Processes
Day 3: Innovations in Pharmaceuticals & Immunology

ASSOCIATESHIPS

Research Associateship in Experimental Nuclear Physics

There is a vacancy for an experimental physicist to join the nuclear physics group as a Research Associate at the Daresbury Laboratory, an establishment of the Science and Engineering Research Council situated in the north Cheshire countryside

The group is involved in a research programme on the Nuclear Structure Facility, a large tandem accelerator which currently is operating at up to 20 MV on terminal.

Currently, the principle areas of study are: direct reactions with light and heavy ions, production of exotic nuclei far from stability, nuclei with very high angular momentum, nuclear breakup and fragmentation and studies of isotope shifts and hyperfine structure using laser-induced resonance fluorescence Experimental equipment includes a Q3D magnetic spectrometer, advanced gamma-ray and neutron detection apparatus, and a 1m diameter scattering chamber An isotope separator with an associated dilution refrigerator and a beam line for laser studies has recently been brought into full operation, a recoil separator is in an advanced commissioning stage, and a heavy-ion polarised source is under construction

Applicants (male/female) should possess a PhD degree or expect to obtain one during 1985

An appointment will be made at a salary between £9,977 and £11,220 per annum depending on age, ability and experience The post is available for a fixed term of three years and is superannuable.

CLOSING DATE: Sunday 30th June, 1985

For further information please write or telephone.
Dr. J. Lilley on Warrington (0925) 65000 Ext 558

Application forms may be obtained from and should be returned quoting reference DL/912 to:

ASSISTANTSHIPS

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
COURTAULD INSTITUTE OF BIOCHEMSITRY
A POST DOCTORAL RESEARCH ASSISTANTSHIP IN MOLECULAR BIOLOGY

financed by The Cancer Research Campaign is available for work in a Molecular Toxicology group examining the role of glutathione and glutathione transferases in carcinogenesis, the cancer cell and cancer chemotherapy. The successful applicant would join several other molecular biologists from this group who work in association with Professor Roger Craig's Medical Molecular Biology Unit. The post is tenable for three years and the salary will be on the 1A scale according to age and experience.

Applications, in writing with curriculum vitae together with the names of two referees should be sent to: Professor Brian Ketterer, Cancer Research Campaign Molecular Toxicology Group, Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London W1P 7PN. (6621)P

THE SCHOOL OF PHARMACY
University of London
DEPARTMENT OF PHARMACEUTICAL CHEMISTRY
POSTGRADUATE AND POSTDOCTORAL RESEARCH ASSISTANTSHIPS
in Chemical and Biological NMR Spectroscopy

Candidates should have shown scholarly achievement in chemistry, biochemistry, biophysics or pharmaceutical chemistry. Research in the department includes synthetic and medicinal chemistry, peptide and protein chemistry, recombinant DNA, receptor structure and function, enzyme structure and function, metabolism, surface and colloid chemistry, electroanalytical chemistry, mass spectroscopy, NMR spectroscopy, light scattering and diffusion

Emphasis is placed upon applications of chemistry and biochemistry to the pharmaceutical sciences.

Salaries offered (Research Assistants) range from £6,600 — £12,150 pa plus £1,233 pa London Allowance.

Applications, which should include the names of two referees and two copies of CV should be sent to Personnel Officer, The School of Pharmacy 29/39 Brunswick Square, London WC1N 1AX. (6673)P

DURHAM UNIVERSITY
DEPARTMENT OF PHYSICS
Applications are invited for a SERC funded
POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

Tenable for 3 years from 1 October 1985 for work in Observational Cosmology using machine measured photographic data, spectroscopic and CCD photometric data for large samples of galaxies and QSOs.

Initial salary £7,520 — £8,920 per annum on Range 1A plus superannuation

Applications (3 copies), naming three referees should be sent by 24 June 1985 to the Registrar, Science Laboratories, Durham DH1 3LE from whom further particulars may be obtained. (6644)P

SEMINARS and SYMPOSIA

FIRST INTERNATIONAL SYMPOSIUM ON CELLULAR ENDOCRINOLOGY

"From Embryos to Cells. Hormonal Control of Differentiation," **12 to 16 August 1985, Lake Placid, New York.** Sponsopred by the W. Alton Jones Cell Science Center, Inc Symposium co-chairmen, Drs. Gorden H. Sato, Ginette Serrero, and Jun Hayashi. Symposium will include lectures and afternoon poster sessions. **For further information and registration forms, please call: Carla Cheyne, Symposium Secretary, telephone. 518-523 1252** (NW1789)M

ACCOMMODATION

PROFESSOR OF Pharmacology at Catholic University Rome in London for Academic Year Sept 1985 to July 1986. Will be working with Prof Gv Born, FRS, King's College, Strand & with Prof A Maseri, Royal Postgrad Med Sch, Hammersmith Hospital Seeking accommodation for himself wife & 1 child for above period Requirement 2/3 bedroom flat/small house to rent up to £140 p/wk. Please reply urgently Gvr Born, Pharmacology, King's College, Strand London WC2R 2LS. (6655)S

CONVENIENT·INFORMATIVE·TIMELY·PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1 ■ You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2 ■ You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences. . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3 ■ You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4 ■ You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

7A5C

Why this magazine and more than 1,000 others let us go over their books once a year.

Some magazines, we're sorry to say, keep their readers undercover. They steadfastly refuse to let BPA (Business Publications Audit of Circulation, Inc.) or any other independent, not-for-profit organization audit their circulation records.

On the other hand, over 1,000 publications (like this one) belong to BPA. Once a year, BPA auditors examine and verify the accuracy of our circulation records.

This audit provides the name, company, industry and job title of every reader each publication reaches. The information helps advertisers to determine if they are saying the right thing to the right people in the right place.

It also helps somebody else important: you. Because the more a publication and its advertisers know about you, the better they can provide you with articles and advertisements that meet your informational needs.

BPA. For readers it stands for meaningful information. For advertisers it stands for meaningful readers. Business Publications Audit of Circulation, Inc.

DEPARTMENT OF BIOCHEMISTRY

CHAIR OF BIOCHEMISTRY

Applications are invited from suitably qualified Biochemists for the post of Professor of Biochemistry which will carry with it in the first instance the Headship of the Department of Biochemistry & Soil Science. The appointment will be from as early a date as can be arranged. The salary will be in the professorial range (minimum £18,070).

Further particulars can be obtained from the Secretary and Registrar, UC NW, Bangor, Gwynedd, LL57 2DG.

Ten copies of the application (one from overseas applicants), together with the names and addresses of three referees, should be sent to reach the Secretary and Registrar by 1st July 1985. (6669)A

MARIE CURIE MEMORIAL FOUNDATION
Research Institute

GROUP LEADERS

As part of a planned expansion of these laboratories we invite applications for newly created scientific posts at group leader lelvel. We seek independent scientists with proven expertise in molecular and/or cellular biology to establish groups investigating fundamental aspects of malignant phenotype in human cancer.

Salaries and research expenditure are internally funded. Equipment and technical support are readily available. These posts are tenable for 5 years in the first instance (subsequent tenure will be dependent upon peer review). Salary, starting date etc are negotiable.

Send CV to Dr G Currie, Marie Curie Memorial Foundation, Research Institute, The Chart, Oxted, Surrey RH8 0TL. Telephone 088388-2306/7. (6614)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
BIOPHYSICS GROUP

RESEARCH ASSISTANT IN PROTEIN CRYSTALLOGRAPHY

to be appointed for structure determination work on the industrially-important enzyme xylosse isomerase, on a project sponsored by the SERC Protein Engineering Steering Group. This is an opportunity for a trained crystallographer to gain experience in protein structure determination, and to participate in a protein engineering programme.

Applications including curriculum vitae and names of two referees should be sent to Mrs A Varsey, Biophysics Group, Blackett Laboratory, Imperial College, London SW7 2AZ. (6634)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

DEPARTMENT OF IMMUNOLOGY

POSTDOCTORAL RESEARCH FELLOW

Required for a three year position funded by The Wellcome Trust to join an existing team characterising the effects of various chemical enzyme inhibitors on the immune system with the eventual aim of modulating immune responses clinically. Applicants should have a background of the biosciences, preferably with some immunological experience.

Scientific enquiries to Dr A Johnstone (01-672 1255 ext 4756) and further particulars and application forms from the Personnel Officer, St. George's Hospital Medical School, Cranmer Terrace, Tooting, London SW17 0RE (ext 4873). Closing date 27 June 1985. (6628)A

RESEARCH CENTER DIRECTOR

Applications and nominations are invited for a Director, Center for Atmospheric and Biospheric Effects of Combustion, located in the Applied Science Division. The scope of the Center is interdisciplinary and includes four major areas: Combustion and Abatement, Atmospheric Pathways and Chemistry, Radiative Balance, and Ecosystem Pathways and Effects. The Director will coordinate the efforts of a number of scientists, including chemists, physicists, engineers, biologists, geologists, meteorologists, and energy analysts to carry out the objectives of the Center; will be responsible for obtaining research support from governmental and non-governmental organizations; will represent the Laboratory at various related national and international meetings; and will also carry out research within the Center. This position requires a Ph.D., and a record of distinguished leadership, outstanding research accomplishments and an international reputation in one or more of the above areas. Experience and background in program planning, development, implementation, administration and evaluation is required. The incumbent should also have experience in obtaining research funds and have a familiarity with organizations that provide these research funds. Salary will be negotiable. The successful candidate will be appointed a Senior Staff Scientist at the Lawrence Berkeley Laboratory.

Applications and/or nominations should be forwarded to: Lawrence Berkeley Laboratory, One Cyclotron Road, Employment Office 90-1042, Berkeley, CA 94720. Please specify Job A/3330. An Equal Opportunity Employer M/F/H. (NW1777)A

LAWRENCE BERKELEY LABORATORY

Cardiovascular Group Leader

Roche is a major multinational pharmaceutical company with a firm commitment to the research and development of novel drugs.

A senior vacancy has arisen in the recently restructured department of Biology for an innovative and enthusiastic scientist to form and lead a new group within the Cardiovascular section.

The successful candidate will play a key role in the cardiovascular research programme, reporting to the Head of Cardiovascular Biology. He/she will have a high degree of scientific autonomy, but will also be expected to interact effectively with Chemists, Biochemists and other Pharmacologists as part of a multidisciplinary approach to drug research.

Ideal qualifications for the post would be a PhD in pharmacology plus a few years experience of industrial Cardiovascular research encompassing both in vivo and in intro techniques.

Research facilities at the Hertfordshire based UK Research Division Headquarters are outstanding as are the company benefits/salary we can offer you.

To take things further, call **Mrs Ann Judge** on **Welwyn Garden City 328128** or write to her, enclosing details, at

Roche Products Ltd,
PO Box 8,
Welwyn Garden City, Herts. AL7 3AY.

ROCHE

(6684)A

NORTH EAST BIOTECHNOLOGY CENTRE

Applications are invited for the following posts which will be based at:

TEESSIDE POLYTECHNIC

in the Department of Chemical Engineering.

READER IN BIOTECHNOLOGY

To lead research teams and supervise research students and develop research projects in areas of interest to the NEBC. The major strengths of the Centre are in Fermentation, Microbial Physiology and Downstream Processing of biological products.

Applicants should be well qualified academically in a discipline related to Biotechnology or Biochemical Engineering and will be expected to hold a PhD and have made a significant contribution to the literature relevant to the post.

Industrial experience would be preferable and membership of a professional institution an advantage.

Salary: £13,095 – £16,467 per annum.

PRINCIPAL LECTURER IN BIOCHEMICAL ENGINEERING

To take responsibility for the operation and further development of the Biochemical Engineering content of courses in process engineering run jointly by the department of Chemical Engineering and the North East Biotechnology Centre.

It is expected that the successful candidate will also undertake research projects, especially in aspects of downstream process design.

Applicants should be well qualified in Biochemical Engineering or a discipline of fundamental importance to this subject area. They will have demonstrated a proven research record in a relevant area, an effective approach to student teaching and appropriate industrial experience. Members of an appropriate professional institution would be an advantage.

Salary: £13,095 – £14,580 (work bar) – £16,467 per annum.

The salary on appointment will be no greater than £14,580 per annum.

LECTURER II/SENIOR LECTURER BIOCHEMICAL ENGINEERING

A Biochemical Engineer to join a team of Biotechnologists promoting research, teaching and consultancy in the North East Biotechnology Centre. The team will be expected to develop teaching and research programmes in one or more of the following areas: Downstream Processing, Control of Fermentation Processes, and the Application of Microbial Physiology to Fermenter Design.

Applicants should be well qualified academically in or a discipline related to Biotechnology or Biochemical Engineering; preferably with some industrial experience; membership of a professional institution would be an advantage.

Salary: £7,548 – £12,099 (efficiency bar) – £13,128 (work bar) – £14,061 per annum.

An appointment will be made at Lecturer II level and the salary on appointment will be no greater than £12,099 per annum.

Closing date for applications in respect of all posts: 24 June 1985.

An Equal Opportunity Employer.

Application forms and further particulars from: Personnel Section, Teesside Polytechnic, Borough Road, Middlesbrough, Cleveland TS1 3BA. Tel: 0642 218121 Extension 4114. (6636)A

THE UNIVERSITY OF ALBERTA

invites applications for the

CANADIAN PACIFIC – ALBERTA AGRICULTURE CHAIR IN PLANT BIOTECHNOLOGY

The University of Alberta is seeking an established scientist to occupy the Canadian Pacific – Alberta Agriculture Chair in Plant Biotechnology. The occupant of the chair will be expected to carry out research related to the improvement of agriculture in Western Canada, to provide leadership within the area of plant biotechnology in the Faculties of Agriculture and Forestry, and Science, and to communicate actively with the agricultural sectors of industry and government. Candidates presently located outside the scientific university community will be given serious consideration, although scientific credentials will be of paramount importance.

The successful candidate will be a member of the Department of Plant Science, in the Faculty of Agriculture and Forestry. The Faculty of Agriculture and Forestry has ninety academic members housed in a modern, well-equipped research complex. In addition, within the Facilty of Science, members of the Departments of Botany, Genetics, and Microbiology are currently involved in basic and applied plant research. The University of Alberta (approximately 25,000 students) is located in the capital city of Alberta. **Please send curriculum vitae, names and addresses of at least three referees, and an outline of research interests, including reprints of relevant publications, to:**

Dr. Mary Spencer
Department of Plant Science
Faculty of Agriculture and Forestry
University of Alberta
Edmonton, Alberta T6G 2P5
Canada

Closing date for receipt of applications is August 31, 1985. Salary will be by negotiation. Appointment will commence on January 1, 1986, or as soon as possible thereafter.

The University of Alberta is an equal opportunity employer but, in accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada. (NW1794)A

KAROLINSKA INSTITUTE, STOCKHOLM, SWEDEN

Invites applications for a position as

FULL PROFESSOR IN MOLECULAR BIOLOGY

The Karolinska Institute is seeking an outstanding Molecular Biologist to join the newly formed Biotechnology Center located at Huddinge University Hospital in Stockholm. The successful candidate is expected to develop a vigorous independent research program. He will be expected to interact with other research teams within the center and in other departments as Karolinska Institute working in related fields. Funding for 3 Post-Doctoral positions, 3 graduate students, 1 Secretary, 4 Technicians and Instruments as well as supplies will be available for the successful candidate.

Application including C.V., a short summary of previous scientific and educational experience, proposal for future research, list of publications as well as reprints or copies of publications or manuscripts (four copies of each) should be received at Karolinska Institutes Registratorskontor, Solnavagen 1,S-104 01 Stockholm, no later than Thursday June 13th, 1985. Applicants who wish to have a later deadline may submit material so that it reaches the above address no later than July 4th, 1985, provided that they, no later than June 13th, make clear to the Karolinska Institute (same address as above) that they wish to apply for the position, and that they state what material they will submit later.

Further information can be obtained from Professor Jan-Oke Gustafsson (Tel. No. 8/7463351) and Dr. Rune Toftgord (Tel. No. 8/7463361). (W1897)A

Tenure track Assistant Professor positions are available in the Department of Pharmacology, University of Iowa, College of medicine. Applications are invited from well-trained individuals who possess the Ph.D. and/or M.D. degree and who are active in an area suitable for development of a vigorous research program related to molecular and cellular pharmacology or more traditional pharmacological disciplines. The University of Iowa is an equal opportunity/affirmative action employer. Submit curriculum vitae and names of three references to:

Search Committee
Department of Pharmacology
Bowen Science Building
University of Iowa
Iowa City, IA 52242
(NW1762)A

ENDOCRINOLOGY BIOCHEMISTRY/ PHYSIOLOGY

Postdoctoral Opportunities

Broad range of Endocrine research projects: (i) isolation and identification of pituitary and lung peptides; (ii) physiologic and pharmacologic action; (iii) growth and control of function of fetal adrenals; (iv) role of growth factors in fetal development.

Send curriculum vitae, bibliography, three letters of recommendation, and short statement regarding career goals, interests and experience to: Dr Samuel Solomon, Endocrine Laboratory, Royal Victoria Hospital, 687 Pine Ave. West, Montreal, Quebec H3A 1A1. (NW1772)A

SPECIAL RESEARCH INITIATIVES

1. **Research Fellow**
   Analytical Atomic Spectroscopy
2. **Research Assistant**
   Cretaceous Micropalaeontology
3. **Research Technician**
   Fish Disease/Cell Culture

For further details and an application form, please contact Personnel Officer at the address below or telephone (0752) 264639.

Closing date for applications: 21 June 1985.

Bureau of Mineral Resources, Geology & Geophysics

Canberra

MARINE RESEARCH GEOPHYSICISTS

The Division of Marine Geosciences and Petroleum Geology in the Australian Bureau of Mineral Resources, Canberra, has vacancies for two Marine geophysicists, one being at senior level.

The principal research aims of the Marine Division are to define the regional geological framework, petroleum prospectivity and evolution of the sedimentary basins of Australia's extensive continental shelf and margins; further to develop new scientific concepts of basin structures and evolution of passive margins and also the active margins of the South Pacific. The main objective is the stimulation of ongoing programs of offshore petroleum exploration. The Division has recently acquired a research vessel with full multichannel seismic capability and seismic processing centre.

SENIOR MARINE GEOPHYSICIST:

to initiate and lead research and resource assessment programs on the Australian Continental Margins and in Australian Territorial waters.

The successful candidate should have a strong background of research experience and an international reputation. He/she should be experienced in multichannel seismic operations, seismic structural and stratigraphic interpretation and in aspects of geohistory analysis as well as have associated experience in other fields of marine geophysics and petroleum. **(Salary at SPRS/PRS level depending on qualifications and experience.)**

MARINE GEOPHYSICIST:

to undertake research and resource assessment programs on the Australian Continental Margins and in Australian Territorial Waters.

The successful candidates should have a history of research, be experienced in multichannel seismic operations, in seismic structural and stratigraphic interpretation and in at least some aspects of geohistory analysis. Associated experience in other fields of marine geophysics and petroleum would be valuable. **(Salary at SRS/RS level depending on qualifications and experience.)**

Qualifications for Both Positions:

A Ph.D (or equivalent) in marine geophysics together with demonstrated research ability.

Salary:

Research Scientist (RS) A$26001-32083
Senior Research Scientist (SRS) A$33209-38243
Principal Research Scientist (PRS) A$39692-45083
Senior Principal Research Scientist (SPRS) A$47501-52212

Conditions:

Conditions of service include superannuation for appointees, long service leave, cumulative sick leave, four weeks annual leave and assistance with removal expenses to Canberra. Permanent appointment is available to Australian Citizens. A term engagement will be considered for persons not meeting this criterion.

Canberra, the national capital, is located approximately 280km southwest of Sydney and has excellent educational, recreational and sporting facilities.

Applications together with full personal and professional details and the names of at least three referees should be sent to:

The Director,
Bureau of Mineral Resources,
GPO Box 378, Canberra ACT
2601, AUSTRALIA.

Applications close 21 June, 1985.

AUSTRALIA

Cell Biologist (PhD)

elf bio recherches

Elf Bio Recherches, a subsidiary of Elf Aquitaine and Sanofi, specialises in biotechnology. It is looking for a Cell Biologist for its laboratory of animal cell physiology and fermentation. This laboratory (2 scientists and 3 technicians) forms part of the recombinant animal cell technology unit. The position is to investigate the role of physiological factors involved in the expression of genes cloned into animal cells. Candidates should have a profound knowledge of animal cell physiology. Experience in medium or large-scale tissue culture will be an advantage. Knowledge of French would be appreciated. Elf Bio Recherches R&D facilities are located in the Toulouse area, in Southern France. Curriculum vitae and list of publications, together with a handwritten letter of application, should be sent to M. Fabre quoting reference **B/T 2018N.**

NATIONAL OPTICAL ASTRONOMY OBSERVATORIES

Associate Director-NOAO and Director-Cerro Tololo Inter-American Observatory — Applications and nominations are invited for the position of Director, Cerro Tololo Inter-American Observatory. The position reports to the Director NOAO and carries the added designation of Associate Director, NOAO. The incumbent will be a key member of a management team who plans and guides the development of NOAO as a program characterized by authoritative in-house science and imaginative and effective support to the user community. The position will be located in La Serena, Chile, and will carry explicit responsibilities for the planning, implementation, and oversight of AURA's program in Chile. The post offers excitement, challenge, and the promise of deep personal satisfaction derived from direct participation in the growth of an institution dedicated to the highest standards of in-house research, service to the astronomical community, and innovative approaches to astonomy. Applicants must have an earned doctorate in astronomy, or a closely related physical science, and a distinguished record of achievement in astronomy; evidence of leadership ability of a high order will also be sought. Interested individuals who feel that their background and temperament match the opportunities and inherent challenge of this position are invited to forward applications, with names of at least three people from whom a confidential evaluation can be sought to The Chair, Search Committee for Director CTIO, National Optical Astronomy Observatories, 1002 North Warren Avenue, Tucson, AZ 85719. Closing date for applications is July 31, 1985.

Further information can be obtained from Dr. John T. Jefferies, Director NOAO, at 602/881-1960. An EEO/AA Employer.

(NW1786)A

LUDWIG INSTITUTE FOR CANCER RESEARCH
UNIVERSITY OF SYDNEY

Post Doctoral Research Fellow

Applications are invited from Post Doctoral Scientists for a Research Fellow to join a group studying in vivo growth regulation of solid tumours, microenvironment and the effects of cytotoxic drugs. Techniques currently in use employ tissue culture, syngeneic and xenogeneic animal tumours, and clinical material, with an excellent flow cytometry facility.

Applicants should possess a good background in cellular biology, and some experience in tumour growth kinetics would be an advantage.

An attractive salary within the range A$22,614-A$25,246 p.a. will be negotiated.

Further information from Dr. D. Hedley, (02) 692 3675/76.

Applilcations should be addressed to:

The Administrator,
LUDWIG INSTITUTE FOR CANCER RESEARCH,
Blackburn Building,
University of Sydney, NSW 2006. Australia.

(W1896)A

MRC
MEDICAL RESEARCH COUNCIL
CLINICAL PHARMACOLOGY UNIT
UNIVERSITY DEPARTMENT OF CLINICAL PHARMACOLOGY — OXFORD

NEUROCHEMIST

Applications are invited for a MRC SHORT-TERM NON-CLINICAL SCIENTIFIC post in this MRC Unit, tenable for 3 years in the first instance. Candidates with some post-doctoral experience will be preferred.

The successful candidate will be required to study the neuro-chemical mechanisms by which neurotransmitter systems respond to the short- and long-term effects of psychotropic drugs. Knowledge and experience of the biochemical mechanisms of neuronal membrane function, neurotransmitter synthesis and release, and techniques of brain slice and synaptosome incubation and stimulation would be advantageous. This work has strong links with an active clinical psychopharmacology section.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information and an application form may be obtained from Professor D.G. Grahame-Smith, University Department and MRC Unit of Clinical Pharmacology, Radcliffe Infirmary, Oxford OX2 6HE (Oxford (0865) 241091), with whom applications, including a full curriculum vitae and the names and addresses of two professional referees, should be lodged by 24th June 1985.

(6613)A

AN ACTIVE FERTILITY AND IN VITRO PROGRAMME IS DUE TO OPEN AT THIS HOSPITAL ON 1st AUGUST 1985

Applications are invited for the following position, for which date of commencement will be by mutual agreement.

TECHNICAL ASSISTANT/EMBRYOLOGIST

The successful applicant will be expected to undertake both routine laboratory and research work. Research is currently undertaken in collaboration with MRC (Carshalton) and the Institute of Animal Physiology (Cambridge).
Experience in mammalian embryology would be desirable and a PhD or MSc in reproductive physiology or embryology would be an advantage, but is not essential.
The Hospital offers a generous salary and excellent benefit package.
Applicants should forward a Curriculum vitae, including the names of three referees to: The Personnel Department, Humana Hospital Wellington, Wellington Place, London NW8
Closing Date 22nd June 1985. (6599)A

Humana Hospital Wellington
Wellington Place London NW8 9LE

UNIVERSITY OF WISCONSIN-MADISON AQUATIC BOTANIST

RESEARCH ASSOCIATE (postdoctoral) position available by 1 June, 1985, for laboratory and lake studies on integrated control of Eurasian watermilfoil and impact of control strategies on water quality. Additional experience in water chemistry, limnology, or mycology desirable. Funding for two years. Salary competitive and commensurate with qualifications.

Send résumé, including the names of three referees, to: Dr. John H. Andrews, Department of Plant Pathology, 1630 Linden Drive, Madison, Wisconsin 53706.

An affirmative action-equal opportunity employer.

(NW1781)A

POST DOCTORAL RESEARCH

position is available to study the molecular biology of the enzymes involved in connective tissue degradation. A research background in biochemistry or molecular biology is advantageous. Applicants should send curriculum vitae and three references to Gregory I. Goldberg, PhD, Washington University School of Medicine, Box 8123, St. Louis, Missouri 63110.

Equal Opportunity/Affirmative Action Employer.

(NW1788)A

MOLECULAR IMMUNOLOGY POST-DOCTORAL SCIENTIST

Salary from £9,000

Celltech, a leader in the field of biotechnology, has achieved its present success in the space of five years. Pioneers in several areas, our achievements are based on the foundations of scientific excellence, innovation and commercial expertise.

Celltech's Molecular Immunology group is expanding its activities in the molecular cloning and expression of immunological targets, principally antibodies. We are looking for a Molecular Biologist/Immunologist, either a post-doc or a graduate expecting soon to finish a PhD. Experience in molecular or cellular immunology would be desirable.

We are an ambitious and forward looking company, which places as much emphasis on its people as its products. You will work in a small friendly team, gaining invaluable broad-based experience, with plenty of opportunity for advancement.

Please send a detailed c.v. to Jane Walley, Celltech Ltd., 244–250 Bath Road, Slough, Berks SL1 4DY, quoting Ref. 268.

CELLTECH

Express Dairy UK Ltd., one of the country's largest Dairy Food organisations has a vacancy in the Research and Development Department.

DEVELOPMENT ANALYST

c.£8,100

Working in a small team, this position involves analytical instrument evaluation and method development. You will be reporting to the Technical Advisor — Rapid Analytical Method Development and should be a Graduate in Analytical Chemistry with at least one year's experience in modern techniques of analysis associated with the food industry.

A current driving licence is essential.

In addition to the salary detailed, 22 days holiday and membership of the Company's pension scheme are available on completion of the necessary qualifying period.

Application forms obtainable from:

Mr. G. D. Evans,
Personnel Officer — Central Staff,
Express Dairy UK Ltd.,
Block I, 430 Victoria Road,
South Ruislip,
Middlesex, HA4 0HF.
Tel: 01-845 2345 Ext. 3551/3370.

Immunodiagnostics

Cambridge BioScience Corporation, a biotechnology company specializing in infectious disease diagnostics offers exciting positions in its Hopkinton, Massachusetts laboratories. We are seeking advanced level scientists as well as research associates.

Molecular Biology

- All levels with extensive background in recombinant-DNA, cloning and expression, minimum of 2 years academic or industrial experience.

Virology/ Immunology

- Ph.D. level with experience in clinical virology
- Experience in hybridoma development
- Working knowledge of molecular virology

Cambridge BioScience offers a unique and stimulating environment and close working associations with academic institutions. **Qualified applicants should send resume and salary requirement to: Cambridge BioScience Corporation, Personnel Department, 35 South Street, Hopkinton, MA 01748.**

(NW1806)A

Cambridge BioScience

Experimental Nuclear Physicists

There are vacancies for experimental physicists to join the Nuclear Structure Division at Daresbury Laboratory, an establishment of the Science and Engineering Research Council which operates major national facilities for scientific research.

The group is involved in carrying out and supporting a research programme on the Nuclear Structure Facility (NSF), a large tandem accelerator which is operating at up to 20 MV on terminal.

Senior Scientific Officer

Ref. DL/911

The successful applicant will be required to organise and direct work necessary for the operation, maintenance and development of major equipment for charged particle identification and detection used in programmes aimed at studies of nuclear collision dynamics, spectroscopy, and nuclei far from stability. Candidates will be expected to carry out research in conjunction with university users on the NSF and to play an active role in initiating and developing new programmes. Other duties will involve the overall coordination and scheduling of the scientific programme and the assessment of future needs for instrumentation and other facilities on the NSF.

Applicants (male or female) should have a good honours degree (or equivalent qualification) in physics and several years postgraduate experience in experimental nuclear research. A Ph.D qualification in nuclear physics and a period of relevant post-doctoral experience would be an advantage.

Higher Scientific Officer

Ref. DL/913

The successful applicant will be required to liaise with university research teams using the NSF. Candidates will also be expected to collaborate in nuclear research programmes and to play an active role in initiating and developing new programmes. Other duties will involve work on the design and development of major equipment through to commissioning, operation and maintenance. As a member of the in-house team of scientists he/she will be expected to provide expertise in the methods of experimental nuclear physics to aid and direct the technical and scientific support staff in operating the NSF and for diagnosing problems as they arise.

Applicants (male or female) should have a good honours degree (or equivalent qualification) in an appropriate discipline with a period of relevant post-graduate experience. A Ph.D degree in nuclear physics and a period of post-doctoral experience in experimental nuclear research would be an advantage.

The salary scales according to qualifications and experience for the Higher Scientific Officer and Senior Scientific Officer posts are £7,435 to £10,039 per annum and £9,329 to £12,050 per annum respectively. These salary scales are currently under review.

There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

CLOSING DATE: 30th June 1985.

For further information please write or telephone Dr. J. S. Lilley on Warrington (0925) 65000, Ext. 558.

Application forms may be obtained from and should be returned quoting the appropriate reference number to: The Personnel Officer, Science & Engineering Research Council, Daresbury, Warrington, WA4 4AD. (6624)A

Daresbury SCIENCE & ENGINEERING RESEARCH COUNCIL

Faculty Position available, tenure-track, in molecular genetics, with a special interest in membranes. Applicants should have research background in recombinant DNA technology (preferably also in somatic cell genetics) and working knowledge of membrane proteins. M.D. and/or Ph.D. in appropriate field required. Successful candidate will hold tenure-track appointment (Assistant or Associate Professor, depending upon qualifications) in Department of Physiology and Molecular Biophysics at Baylor College of Medicine. Joint appointments in relevant academic departments also possible. Laboratory space and basic equipment provided and initial laboratory support available. Successful candidate will devote majority of his/her effort to establishing and maintaining an independent research program related to the main interests of the Department. The Department is building a strong program in membrane biophysics with expertise in electrophysiology, membrane biochemistry, reconstitution, and modelling. **Send vita, a brief description of past and present research experience, and names of three or more references to**

Dr. A. M. Brown, Incoming Chairman,
Physiology and Molecular Biophysics Department

Baylor College of Medicine,
One Baylor Plaza,
Houston, Texas 77030.

An Equal Opportunity A/A Employer

(NW1814)A

SENIOR SCIENTIFIC PROGRAMMER

National Optical Astronomy Observatories
The National Optical Astronomy Obervatories

(NOAO) needs a senior level programmer for its Detector R&D Program in Tucson. Working with scientists and engineers, the position involves development of software to operate state-of-the-art infrared arrays and signal processing equipment for astronomical instrumentation. We require skills in the development of real-time software for data acquisition and process control applications and date reduction and analysis programs. Applicants should have experience in FORTRAN and one of the structured languages such as "C". Experience in a real-time programming environment and software signal procesing is required. Knowledge of FORTH, UNIX , and DEC computers is desirable. An Electrical Engineering or Computer Science degree and at least five years experience as a programmer are required. Other degree background will be considered with more extensive programming experience.

The NOAO, headquartered in Tucson, Arizona, operates Kitt Peak National Observatory near Tucson; National Solar Observatory sites at Sacramento Peak, New Mexico, and on Kitt Peak; Cerro Tololo Inter-American Observatory in Chile, and the Advanced Development Program in Tucson.

Offering forefront technology challenges, and unclassified workplace, and a Sunbelt location, we are an EEO/AA employer with an excellent compensation package, including 24 days annual vacation and, after one year, a fuly vested retirement plan.

Send résumé in confidence to: Judy Ruffino, Personnel Manager, P.O. Box 26732, Tucson, Arizona 85726.

Equal opportunity employer. (NW1804)A

MACROMOLECULAR CRYSTALLOGRAPHER

Three-year Postdoctoral Research Associate position. Seeking motivated, talented person with experience in experimental aspects of structure determination to conduct x-ray diffraction studies. Several ongoing projects at different stages under the overall theme of intermolecular interactions. Excellent facilities for data collection, reduction, and analysis: rotating anode generators area detector, oscillation/precession cameras, 2 VAX 11-750s, node to CRAY, color vector and raster graphics. Exciting work environment within a strong departmental structure group including six faculty crystallographers. Salary negotiable. Superb working setting in new building located on cliffs overlooking ocean. Send C.V. and three references to:-

Elizabeth Getzoff or John Tainer, Department of Molecular Biology — MB3, Research Institute of Scripps Clinic, 10666 North Torrey Pines Road, La Jolla, CA 92037. (NW1799)A

THE ROYAL VETERINARY COLLEGE
University of London

Division of Preclinical Studies
Department of Physiology, Biochemistry and Pharmacology

Lecturer in Biochemistry

Applications are invited from veterinary, science, or medical graduates for a post involving both teaching and research which it is hoped to fill by 1st October 1985. An interest in metabolism and previous experience in lipid and lipoprotein biochemistry would be of advantage.

Salary Scale (under review): £8,753 to £16,158 including London Allowance. Universities Superannuation Scheme, Removal expenses up to £1,400 reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. (Tel: 01-387-2898).

Closing date for applications: 17 June 1985. (6630)A

UNIVERSITY OF NATAL
DEPARTMENT OF ZOOLOGY
ZOOLOGY

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin for appointment to the post of:

LECTURER IN BIOLOGY

Minimum qualifications would be a PhD in Zoology, Botany, Biology or a closely allied field and/or suitable academic or research experience.

The successful applicant will be responsible for teaching a first year introductory course, which is essentially a service for students in the Faculty of Agriculture. The four major areas covered by the course are Cell Biology, Plant Anatomy and Development, Animal Physiology, and the Ecology and Evolution of Animals and plants. No particular area of expertise is required beyond a sound and comprehensive knowledge of biology, but the appointee will be encouraged to actively participate in research and to supervise post-graduate students.

The appointment carries an attractive salary package, details of which are obtainable from the Staffing Section on request (telephone 0331-63320). The salary offered will be determined according to the qualifications and/or experience of the successful applicant.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, service bonus, staff bursary, housing loan, and subsidy schemes, long leave conditions and travelling expenses on first appointment, are available from the Registrar, University of Natal, PO Box 375, Pietermaritzburg, South Africa, 3200, with whom applications on the prescribed form must be lodged not later than 28 June 1985 quoting reference PMB 29/85.

Application forms for overseas applicants are available from the Secretary, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. (W1895)A

COMMONWEALTH AGRICULTURAL BUREAUX

THE LEADING WORLD AGRICULTURAL INFORMATION SERVICE FOR SCIENTISTS AND TECHNOLOGISTS

SCIENTIFIC INFORMATION OFFICER

REQUIRED AT THE
COMMONWEALTH BUREAU OF PLANT BREEDING AND GENETICS, CAMBRIDGE

Duties:
Preparing abstracts for the Journal *Plant Breeding Abstracts*, which covers world scientific literature in this field: indexing, and answering scientific enquiries.

Qualifications:
A degree in botany, genetics, or a related subject is essential, plus a reading knowledge of at least one European language (Slavonic languages preferred) and the ability to write good English. Applicants must be able to render the contents of scientific publications into concise, accurate and readable abstracts.

Salary:
In the scales £5,909–£8,153 p.a., £7,435–£10,039 p.a. Starting salary according to qualifications and experience.

Application forms and further particulars from
Commonwealth Bureau of Plant Breeding and Genetics
Department of Applied Biology
Pembroke Street, Cambridge CB2 3DX
Tel. No: Cambridge (0223) 358381, etxn.216.
Closing date for applications: 20th June, 1985.

(6689)A

Bureau of Mineral Resources
Geophysics Division
Canberra
GEOMAGNETISM SECTION MANAGER
A$34757 - A$37028

The Geomagnetism Section of the Division of Geophysics, Bureau of Mineral Resources, comprises a staff of 15. The Section is responsible for operating the magnetic observatories and conducting magnetic surveys in the Australian and Antarctic regions, and also runs a modern palaeomagnetic facility. Mission oriented research is carried out in the fields of solid-Earth geomagnetism and palaeomagnetism.

Duties:
The Manager, acting under the Section Head, is responsible for administration of the section, and the co-ordination of magnetic (including palaeomagnetic) observatory and survey operations. The person appointed will be expected to initiate and participate in aspects of the research program.

Qualifications:
An appropriate degree or equivalent, ability to manage a scientific team, experience in magnetic (including palaeomagnetic) observatory and survey operations, the ability to carry out original research in geomagnetism.

Conditions:
The BMR is part of the Australian Public Service. To qualify for permanent appointment, applicants must be Australian citizens. Non-citizens may be appointed under a 3-year contract, with the expectation that they seek permanent appointment. Conditions of service (pension scheme, leave entitlement, etc.) are those pertaining to the Australian Public Service. Moving and settling-in allowances are paid to persons, and their dependent families, appointed from overseas.

Canberra, the national capital, is located approximately 280km southwest of Sydney and has excellent educational, recreational and sporting facilities.

Applications, including a curriculum vitae, statement of research interests, and names of professional referees should be addressed to: Staff Section, Bureau of Mineral Resources, P.O. Box 378 Canberra, A.C.T. 2601, Australia.

Please quote reference: Position No. 2409, Geomagnetism. Applications should be submitted before 30th June 1985. (W1899)A

AUSTRALIA

Consejo Superior de Investigaciones Cientificas
INSTITUTO CAJAL
(Madrid, Spain)

Three permanent research positions will be available in 1985 at The Cajal Institute for Neurobiology. One of the positions is open for neurophysiologist and the other two for specialists in any other branch of Neuroscience. The appointments will be at the Research Associate level. Applicants must be Spanish citizens and have a M.D. or Ph.D. degree.

Further information may be obtained from:
The Director, Instituto Cajal, Velâquez 144, 28006-Madrid, Spain. (w1889)A

Postdoctoral or Research Associate Position

Available July 1, 1985. Project involves function of actin isoforms, post-translationally modified tubulin species, and microtubule-associated proteins. Biochemisty or molecular biology background is desirable; the lab uses these, as well as peptide antibody techniques, HPLC, cell culture, and immuno-staining. Salary depends on experience. Send curriculum vitae and the names of three references to:

Dr. J.C. Bulinski, Department of Biology, University of California, Los Angeles, CA 90024. (NW1805)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following positions:

Research School of Earth Sciences
POSTDOCTORAL FELLOW/RESEARCH FELLOW/ SENIOR RESEARCH FELLOW
NOBLE GAS GEOCHEMISTRY

Applications are invited for an appointment in the School's Geochronology and Isotope Geochemistry Group, the field of interest being noble-gas geochemistry. The appointee will work with Dr Ian McDougall, Senior Fellow, in developing research in this field, which is new to the School. The School wishes to make the appointment at the Research Fellow level, but will be prepared to consider applications at the level PDF or SRF.

Noble gas investigations are being initiated to assist in elucidation of the geochemical evolution of the mantle, the mantle-crust system, and the atmosphere. Research initially will concentrate on mantle-derived rocks, with subsequent development of studies on fluids in the crustal environment. Provision of a suitable high-resolution gas-source mass spectrometer is in hand, and construction of appropriate extraction lines is planned.

Persons with suitable backgrounds in the physical sciences, and with particular interests in geochemistry, are encouraged to apply. Experience in noble gas studies on geological samples would be a great advantage.

The appointee will assist in developing the laboratory facilities, and will be expected to undertake discrete projects within this broad field of study. Active collaboration with other workers in isotope geochemistry is envisaged. Enquiries may be directed to Dr I McDougall (062 49 4136).

Closing date: **19 July 1985.** Rf: ES/1.5.1.

Faculty of Science
DEPARTMENT OF ZOOLOGY
POSTDOCTORAL FELLOW

The successful applicant will work on a NH & MRC funded project involving gene cloning of sheep parasites particularly larval tapeworms and liver fluke. Particular interest will be centred on those genes which code for antigens that are involved either in resistance to reinfection or immunopathological phenomina. A principal objective will be to obtain expression of these antigens in prokaryotic systems. Experience in gene cloning techniques is essential and some knowledge of immunological procedures would be highly desirable. The successful applicant will work in the Centre for Recombinant DNA Research, Research School of Biological Sciences (Executive Director: Professor J A Pateman FRS). The position is funded for 3 years. Previous applicants need not reapply as all applications will be considered.

Further information is available from Dr M J Howell, (062) 49 3060 or (062) 49 4225.

Closing date: **15 July 1985.** Ref: FS/1.5.1

CONDITIONS OF APPOINTMENT: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow $A21,411-$24,528 pa; Research Fellow $A24,840-$32,634 pa; Senior Research Fellow $A34,699-$41,390 pa. Current exchange rate is $A1.00 = Stg 0.48.

Grants are provided towards travel and removal, though special conditions may apply to persons appointed to externally funded positions. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. **Applicants should quote the advertisement reference when requesting further particulars and when submitting applications, which should be sent to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. General Information also available from the Secretary General, Association of Commonwealth Universities (Appts) 36 Gordon Square, London WC1H 0PF.**

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER

(W1880)A

UNIVERSITY OF TORONTO
DEPARTMENT OF BOTANY
POSTDOCTORAL FELLOW

required to work in group studying molecular basis of metal-tolerance in micro-organisms and higher plants. Applicants should have experience in recombinant DNA techniques; knowledge of microbial physiology and plant ecology an advantage. Salary is in range of $21,500 Canadian. Position is available immediately. **Please send detailed letter and C.V., plus three letters of reference to Prof. T.C. Hutchinson, Department of Botany, University of Toronto, Toronto, Ontario, Canada M5S 1A1.** (NW1809)A

VICE PRESIDENT FOR RESEARCH
THE UNIVERSITY OF GEORGIA

The University of Georgia invites nominations and applications for the position of Vice President for Research.

Located in Athens, Georgia, The University of Georgia is the nation's oldest chartered state university. The University ranks among the top 50 research institutions in the country and operates with annual research expenditures in excess of $80 million across its 13 schools and colleges.

The Vice President for Research will administer the University's research resources, serve as an executive officer of the University and report to the President. He/she will facilitate and coordinate a vigorous expansion of competitively-funded research programs, and seek new avenues for creative partnerships with the private sector and government agencies. She/he will exert strong leadership in the organisation and funding of new, interdisciplinary research programs, and will formulate reward and incentive systems for faculty participation in sponsored research.

Nominees/applicants should have a record of executive-level accomplishments, knowledge of current R&D environments encompassing national and international perspectives in private, public, and governmental sectors, and should possess a working knowledge of higher education, including the nature and scope of university research activities. Candidates should have the terminal degree or equivalent experience in their discipline, and credentials suitable for appointment at the level of professor in the University.

Nominations should include the nominee's address and telephone number. Applications should include a letter of interest, a curriculum vitae, and the names and addresses of 5 persons who can serve as references. The closing date for receipt of completed applications is **July 15, 1985.** The position may be occupied as early as January 1, 1986.

Address all nominations and applications to:

Vice President for Research Search Committee
c/o Dr Luis M. Proenza
Office of the President
The University of Georgia
Athens, Georgia 30602

The University of Georgia is an Equal Opportunity/Affirmative Action Employer

(NW1795)A

MAMMALIAN CELL BIOLOGIST

A Ph.D. with academic or industrial post-doctoral experience is sought for a position in a multidisciplinary group studying high density mammalian cell culture in the Biotechnology Laboratory of Central Research at The Dow Chemical Company. The successful candidate will have experience in handling multiple cell lines and associated analytical techniques and will have responsibility for the planning, organization and execution of a high priority program in the development of optimal culture conditions.

For further information, please contact:

Dr. Kerr Anderson
Central Research
Biotechnology Laboratory
1701 Building
The Dow Chemical Company
Midland, MI 48674

(NW1808)A

SCOTTISH CROP RESEARCH INSTITUTE
DIRECTOR

The Governing Body of the Scottish Research Institute invites applications for the post of Director which will become vacant on the retirement of Professor C E Taylor CBE in March 1986.

SCRI, which is funded by an annual grant from the Department of Agriculture and Fisheries for Scotland, is a major crop research institute within the Agricultural and Food Research Service. It's research programme requires a wide range of scientific disciplines associated with the production and breeding of arable and horticultural crops.

Candidates should have an established record of scientific leadership and the capability to manage an organisation with over 300 staff.

Salary; £26,909 per annum non-contributary superannuation scheme.

The Institute is an equal opportunities employer.

Further particulars can be obtained from Mr N D Anderson, The Secretary to the Governing Body.

Applications accompanied by a full curriculum vitae and the names and addresses of three referees should be lodged with the Secretary to the Governing Body, Scottish Crop Research Institute, Invergowrie, Dundee DD2 5DA.

Closing date 12 July 1985. (6679)A

DROSOPHILA DEVELOPMENT

University of Arizona

Two postdoctoral positions available to work on molecular aspects of pattern formation and morphogenesis in Drosophila. One position state-funded at the level of Visiting Lecturer, with opportunities for teaching. Salary commensurate with experience. Send CV, statement, and names, addresses, and telephone numbers of at least three referees to: Dr. Danny Brower, Department of Molecular & Cellular Biology, Biosciences West Building, University of Arizona, Tucson, AZ 85721, USA. Position to begin Fall 1985. An equal opportunity/affirmative action employer. (NW1801)A

TWO RESEARCH ASSOCIATE POSITIONS

Available immediately. Experience in proteins and recombinant DNA. Salary $18,000 to $22,000.
Send CV and three references to Dr. O.P. Bahl, Dept. of Biological Sciences, SUNY at Buffalo, Cooke Hall 347, Buffalo, NY 14260. Equal Opportunity/Affirmative Action Employer. (NW1811)A

Post Doctoral Fellow Experimental Pathology

At Smith Kline & French we wish to appoint a Post Doctoral Fellow within a new laboratory of our expanding Pathology Department.

The work will be to apply cell and organ culture techniques to the investigation of cell pathology related to new and model compounds. Integrated projects with histopathologists, EM and clinical pathologists will also be involved.

A PhD and post doctoral experience in the use of *in vitro* techniques applied to experimental pathology is required. Experience in bone marrow CFU and lymphocyte culture would be an advantage.

We offer a competitive salary and benefits for this two year fixed term appointment.

Please write for an application form or send a detailed CV outlining your qualifications and experience quoting reference number N/123/JW to John Ward, Personnel Officer, Smith Kline & French Research Limited, The Frythe, Welwyn, Herts AL6 9AR.

SK&F

UNIVERSITY OF MANITOBA
Department of Plant Science

POSTDOCTORAL POSITION PLANT CYTOGENETICS

Applications are invited for a position available September 1 to carry out research on wheat-rye chromosome substitutions in triticale. These studies concern the use of chromosome banding techniques for the identification and establishment within an isogenic background, disomic substitution lines involving individual chromosomes of rye and their homoeologues from wheat. Experience with chromosome banding techniques and electrophoretic analysis of plant proteins in desirable. The appointment is initially for one year with a maximum of two years. Starting salary from $18,500 to $20,500 per annum according to experience.
Send curriculum vitae with names and addresses of two referees to:- **Dr. E.N. Larter, Department of Plant Science, University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2.**(NW1807)A

DEVELOPMENTAL BIOLOGIST

CORNELL UNIVERSITY MEDICAL COLLEGE

Applications are invited for a senior or junior tenure-track faculty position. Applicants should have at least two years of postdoctoral experience and maintain a research program in early development or morphogenesis, using genetic, recombinant DNA, biochemical, immunological, and/or cell biological tools to explore mechanisms of pattern specification and determination in a vertebrate or invertebrate system. The position includes supervision of graduate students and teaching in a related area.

Send curriculum vitae, research summary, and three letters of reference to: Dr. Rosemary Bachvarova, Developmental Search Committee, Department of Cell Biology and Anatomy, Cornell University Medical College, 1300 York Avenue, New York, NY10021. An Equal Opportunity/Affirmative Action Employer. (NW1767)A

POSITION OPEN

RESEARCH ASSOCIATE POSITION

available immediately to study the dynamics of membrane phase transitions using a novel volume-perturbation kinetic calorimeter which we have developed. We are seeking a person with a Ph.D. in Biochemistry, Biophysics or related field for a Research Associate position to work on this project.
Our calorimeter measures the thermodynamic phenomenon associated with phase transitions in membrane systems via temperatures and pressure changes and optical properties. The person we seek must be able to synthesize artificial lipid membranes in pure form and mixed with other constituents, and be able to reconstitute protein recombinant systems so the proteins retain their native functions. This person will conduct experiments, do some hardware modification, and modify and use computer software for data acquisition and experimental analysis. The individual must have a working knowledge of membrane systems. He/she must also be experienced with computer hardware and software methods for data acquisition, instrument control, data analysis and modelling studies.
Send Curriculum Vitae and names of referees to Dr. Michael L. Johnson, Department of Pharmacology, University of Virginia, Charlottesville, Virginia 22908. An Equal Opportunity/Affirmative Action Employer. (NW1813)A

CELL BIOLOGIST

UNIVERSITY OF ALABAMA AT BIRMINGHAM

Applications are invited for two senior, tenured positions in the Department of Cell Biology at the level of Associate or Full Professor. Candidates must have achieved international recognition in cell or molecular biology, have a productive and well funded research program and be willing to move the program to Birmingham. Preference will be given to individuals employing molecular techniques to study the structure and function of cell components, growth control, regulation of gene expression, cell development or motility. Successful candidates will be offered nationally competitive salaries, excellent laboratory space and facilities, and an outstanding research environment in a rapidly expanding medical center. Ample opportunities exist for teaching in the Schools of Medicine and Dentistry including gross anatomy, neuroanatomy, histology or in a new graduate program in cell biology.

Applicants should send a curriculum vitae and a brief description of past and present research experience and the names of three or more references by July 1, 1985 to: B. R. Brinkley, PhD, Professor and Chairman, Department of Cell Biology and Anatomy, Schools of Medicine and Dentistry, University of Alabama at Birmingham, University Station, Birmingham, Alabama 35294. An Equal Opportunity/ Affirmative Action employer. (NW1785)A

Southampton THE UNIVERSITY

Department of Chemistry

Production and properties of Silicon-on-Insulator materials

A Postdoctoral position will be available from October 1985 for a Physical Chemist or Physicist to participate in a fundamental study of the production of new semiconductor materials. The project will employ a novel combination of techniques, including electrochemistry and in-situ ellipsometry applied to porous silicon substrates, which are being evaluated as the basis of the next generation of fast devices.

Previous experience in electrochemistry or spectroscopy would be an advantage, and some knowledge of computer programming or computerised instrumentation is necessary. The salary will be at a point on the SERC 1A scale commensurate with the age and experience of the appointee.

Applications together with the names of two referees should be sent as soon as possible to: Dr. R. Greef, Chemistry Department, The University, Southampton SO9 5NH, UK, from whom further information can be obtained. (6670)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (UNIVERSITY OF LONDON)

DEPARTMENT OF MEDICAL PROTOZOOLOGY

MOLECULAR BIOLOGIST

A post-doctoral position will shortly become available in this Department for a 3-year period for a suitable individual who wishes to join a team investigating the mechanisms of drug-resistance in malaria, under the direction of the Head of the Department, Professor W. Peters. The project will be carried out in close association with the members of the Wolfson Unit of Molecular Medical Microbiology and Parasitology who are based in this Department. Applicants must have training and experience in recombinant DNA technology and will work closely with other members of the team who are investigating the very practical problem of drug-resistant malaria from other points of view, including the evaluation in depth of promising new antimalarial compounds. The appointment, which will be for up to three years in the first instance, carries a starting salary in the range £8,543 to £13,173 per annum.

Candidates should send, as soon as possible, a full curriculum vitae describing their previous training, research experience and research interests, together with the names of three referees, to the Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1E 7HT. Please quote reference MP2.

(6632)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF BIOCHEMISTRY

Positions are available for a temporary lecturer, postdoctoral worker and SERC-CASE student. All posts are tenable from the 1st of October, 1985.

The temporary lectureship is available for 3 years and results from an MRC-replacement scheme award to Dr H C Nimmo. The appointee would be encouraged to undertake research and to collaborate with existing groups within the Department.

The postdoctoral position is available for 2 years to work with Professor Houslay's group on guanine nucleotide regulatory proteins and their interaction with adenylate cyclase. This appointment is funded by the MRC and will be made within the first three points of the 1A salary scale for research workers.

An SERC-CASE studentship award for the study of a PhD is available to work jointly with Professor Houslay at Glasgow and Dr Baxter at Glaxo. This project is aimed at understanding the physiological importance of the tyrosine kinase activity associated with the insulin receptor. The conditions of this award are as generally applicable to research council studentships.

Further information may be obtained from, and informal enquiries may be made to, Professor M D Houslay, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ, to whom application (3 copies), should be made by 30th June, 1985. (6691)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ZOOLOGY

POSTDOCTORAL RESEARCH ASSOCIATE IN NEUROBIOLOGY

Applications are invited for a postdoctoral Research Associate to work with a small group, supported by the SERC investigating the physiology and structure of insect brain neurones. Interests are both in the operation of synapses which identified visual neurones make amongst each other, and in the function of these neurones in the control of behaviour. In particular, we plan to compare the membrane properties and synaptic structure of different neurones, with the aim of understanding more about the roles of spikes in regulating transmitter release from neurones. Applicants should have experience in ultrastructural or in electrophysiological techniques, and are required either to have or to be close to completing a PhD. The appointment is for 3 years tenable from 1st July 1985 (deferable for up to 6 months).

Salary will be up to £8,450 per annum on the Range 1A scale (£7,520 - £12,150) according to age, qualifications and experience.

Applications (2 copies of curriculum vitae and research experience), plus names of 2 referees, or enquiries to: Dr P J Simmons, Department of Zoology, University of Newcastle upon Tyne NE1 7RU not later than 13th June 1985. (6627)A

NATURE CONSERVANCY COUNCIL

(Commissioned Research —)

(Contract Post)

DEPARTMENT OF ENTOMOLOGY

HIGHER SCIENTIFIC OFFICER DATA HANDLING/ ENTOMOLOGIST

Applications are invited for a one year contract post funded by the Nature Conservancy Council, to be based in the Entomology Department, Rothamsted Experimental Station, Harpenden, Herts. The successful applicant will be responsible for analysing light trap data for moths gathered by the Rothamsted Insect Survey. The project will investigate whether any long term trends are apparent for the polulations of particular moth species, or for the fauna of selected sites. The RIS moth data is stored on computer file and so previous computing experience is essential, and some familiarity with the British moth fauna would be an advantage.

Qualifications. Candidates should have a first or second class honours degree, or equivalent, in computing studies or in zoology and with at least two years relevant postgraduate experience.

Salary depending on age and qualifications. Higher Scientific Officer £7,435 rising to £10,039 per annum.

Application forms and further details are available from Miss B A Meredith, Personnel 1, Nature Conservancy Council, Northminster House, Peterborough PE1 1AU.

The closing date for receipt of completed application forms is 21 June 1985. The Nature Conservancy Council is an equal opportunity employer. (6653)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY PATHOLOGY

MOLECULAR VIROLOGY UNIT

A molecular virology unit has been established to develop novel vectors for the expression of viral antigens in mammalian systems. This unit works in close collaboration with virilogists and molecular biologists in this department and at the Beatson Institute.

Three positions, supported by the National Institutes of Health, are immediately available. Applications are invited for 2 post-doctoral fellows (salary range £8,450 to £10,720 per annum) and a research assistant (£6,600 per annum). The research assistant may apply to register for a higher degree.

The applicants should have experience in recombinant DNA technology and a background in virology would be an advantage. Applications should be sent to, and further particulars may be obtained from, Professor W F H Jarrett, FRS, University of Glasgow Veterinary School, Bearsden, Glasgow G61 1QH (telephone number 041-942 2301). (6692)A

UNIVERSITY OF LONDON THE CARDIOTHORACIC INSTITUTE

DEPARTMENT OF MEDICINE

NEW BLOOD APPOINTMENT

Applications are invited for a "New Blood" appointment in the Department of Medicine. The successful candidate is likely to be a clinical or non-clinical scientist with experience in the application of immunological and cell biological methods to study of the pulmonary macrophage. He or she will be expected to be sufficiently experienced to contribute new basic scientific ideas in this area and to carry these through experimentally in the current programme of research being conducted in the Department of Medicine into the cellular, biochemical and host defence aspects of pulmonary disease. A clinical appointee would be expected to co-ordinate the programme of laboratory research as it is applied to in-patients and out-patients, and to participate in the teaching activities of the Department.

Candidates should not hold a permanent University appointment in the UK. Appointment will be on the Clinical or non-Clinical Lecturer scale. A London Allowance is payable.

Applicants should apply by letter, enclosing 8 copies of their curriculum vitae, a statement of not more than 500 words on why they are applying for this post, and naming 3 referees to The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP from who further particulars can be obtained. Closing date for application 21 June 1985.(6645)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF CHEMICAL AND BIOCHEMICAL ENGINEERING

POSTDOCTORAL AND POSTGRADUATE RESEARCH ASSISTANTS RESEARCH TECHNICIAN

Applications are invited from biochemical and chemical engineers, biochemists and microbiologists for four posts in the Department of Chemical and Biochemical Engineering to work on two research programmes.

(1) Biocatalytic reaction involving water-insoluable organic compounds (supported by SERC).

(2) Extended use of biocatalysts (supported by DTI and seven companies through The Institute for Biotechnological Studies).

Appointments for three years starting as soon as possible will be made on the 1A and 1B scale for research assistants, and grade 3 scale for the technician.

Applications including CV and names and addresses of two referees should be sent to Professor M D Lilly, Department of Chemical & Biochemical Engineering, University College London, Torrington Place, London, WC1E 7JE. (6652)A

THE NATURE CONSERVANCY COUNCIL

SENIOR SCIENTIFIC OFFICER

Co-ordinator for remote sensing of the environment.

The successful candidate will be required to assist with the management and co-ordination of the National Countryside Monitoring Scheme. The duties will include advising NCC staff on digital cartography and the development of NCC's use of satellite imagery for monitoring purposes. Other responsibilities will include liaising with the Department of Environment, Countryside Commission, Countryside Commission (Scotland), Institute of Terrestrial Ecology and other organisations concerned with the monitoring of countryside feature through remote sensing.

Candidates should have a degree in an appropriate subject and at least four years post graduate experience. Essential experience will include digital cartography, photogrammetry, statistical analysis and sampling strategies involving remote sensing, the ability to write and edit the necessary computer software and management experience of remote sensing programmes.

Salary range: £9,329 to £12,050.

For further details and an application form, please contact Mr S Woodfield, Personnel 1, Nature Conservancy Council, Northminster House, Peterborough PE1 1AU to whom completed forms should be returned by the 19 June 1985.

The Nature Conservancy Council is an equal opportunity employer (6654)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GEOLOGY

Applications are invited for the post of

RESEARCH ASSISTANT/ SENIOR RESEARCH ASSISTANT/ RESEARCH ASSOCIATE

to work on a study of fault geometry and mechanics using data from colliery plans and records. Applicants should be graduates in a branch of Earth Sciences and have a good grounding in either structural geology or geophysics. An interest in computing and/or quantitative methods in geology would be an advantage. There will be no opportunity to register for a higher degree. A candidate currently registered for a higher degree will only be considered if thesis submission is imminent.

Appointment will be from 1st July, 1985, initially for one year. Initial salary will be within the range £6,600 — £9,390 per annum.

Applications, together with the names of three referees, should be received not later than 14th June, 1985, by The Registrar, The University, PO Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained.

Quote ref RV/294/N. (6662)A

VICTORIA UNIVERSITY OF WELLINGTON

DEPARTMENT OF BIOCHEMISTRY

TEMPORARY LECTURER IN BIOCHEMISTRY

Applications are invited for the above position, which is available from 1 February 1986. Applicants should have recently obtained a PhD in contemporary biochemistry. The most desirable areas of expertise are those of molecular biology (in particular recombinant DNA technology), molecular enzymology or protein chemistry. The research interest of the Department lie in mechanistic studies in biochemical pharmacology and toxicology with a bias towards projects of agricultural significance. The appointeee will be expected either to redirect his or her expertise into existing projects or to initiate new research compatible with departmental interests. Experience in relevant fields such as biochemical pharmacology or insect biochemistry or toxicology would therefore be advantageous.

Salary will be the range NZ$23,622 — NZ$27,928 per annum. The appointment will initially be for a period of two years. Extension for a third year may be possible depending on the outcome of a review of the Life Sciences at Victoria University.

Conditions of Appointment and method of application are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or the Administrative Assistant (Appointments), Victoria University of Wellington, Private Bag, Wellington, New Zealand, with whom applications close on 26 July 1985. (W1901)A

THE SCHOOL OF PHARMACY

University of London

DEPARTMENT OF PHARMACEUTICAL CHEMISTRY

POSTGRADUATE Research Opportunities in Pharmaceutical Chemistry

Applications are invited for a number of positions for postgraduate research leading to higher degrees. Candidates should have or expect to have a good honours degree in pharmacy, chemistry, biochemistry or biophysics.

Research Council and industrially sponsored projects on offer include.

(a) Diffusion and light scattering of biopolymer systems.
(b) Applications of fast atom bombardment mass spectrometry in pharmaceutical and biological chemistry.
(c) Chemical and biological NMR spectroscopy; and
(d) Synthesis and structure of natural products and peptides.

Applications should indicate area(s) of interest, giving names of two academic referees and two copies of CV and, to be sent to: Personnel Officer, The School of Pharmacy, 29/39 Brunswick Square, London, WC1N 1AX. (6674)A

MICROBIOLOGIST

Molecular Immunology Division

The Molecular Immunology Division of Allelix Inc. is seeking a microbiologist with experience in the culture, maintenance and isolation of clinically important infectious agents for the Product Development Group. The successful candidate will work in a team developing rapid diagnostic immunoassays for the diagnosis of infectious diseases. This individual will possess a Ph.D. in microbiology and at least two years' post-doctoral experience in clinical microbiology. Experience in immunoassay and protein chemistry techniques will be advantageous.

Allelix provides the opportunity to learn from and interact with experienced staff scientists, in addition to the immediate project leader, in a well-equipped laboratory. Salaries and benefits are at fully competitive levels.

Interested candidates are asked to send complete resumés, including three references and quoting file number MI001, to:

Dr. J.G.R. Hurrell

Allelix INC

6850 Goreway Drive
Mississauga, Canada
L4V 1P1

(NW1810)A

UNIVERSITY OF LEICESTER

DEPARTMENTS OF ZOOLOGY AND OBSTETRICS AND GYNAECOLOGY

SENIOR DEMONSTRATOR IN REPRODUCTIVE PHYSIOLOGY

Applicants are invited for a post of Senior Demonstrator in Reproductive Physiology. This will be a joint appointment in the Department of Zoology and Obstetrics and Gynaecology. Applicants should have experience in tissue culture and/or the culturing of mammalian embryos, and should preferably be post-doctoral. The appointee will be required to assist in collaboration with the two departments in developing a programme of extracorporeal fertilisation. There will also be a teaching commitment in the area of cell and developmental biology in the Department of Zoology. The appointment will be for two years.

Initial salary will depend on age and experience on the scale £7,520 to £12,150 (under review).

Further particulars from the Registrar (Appointments), University of Leicester, University Road, Leicester LE1 7RH (telephone 0533 554455 ext 233), to whom applications on the form provided should be sent by 17 June 1985. Informal enquiries can be made to Professor H C Macgregor, Department of Zoology. Telephone 0533 554455 ext 115. (6642)A

UNIVERSITY OF THE WEST INDIES

St Augustine, Trinidad

DEPARTMENT OF MECHANICAL ENGINEERING, INDUSTRIAL ENGINEERING PROGRAMME

LECTURER/ ASSISTANT LECTURER

Applications are invited for the post of Supernumerary Lecturer/Assistant Lecturer in the Department of Mechanical Engineering, Industrial Engineering Programme, specialising in Operations Research and Production/Investment Planning. The appointment will be two years.

Salary scales: Lecturer: TT$54,708 × 1,908 – $66,156 (Bar) × 1,908 – $77,604; Assistant Lecturer: TT$45,480 × 1,908 – $49,296. FSSU. Unfurnished accommodation if available at 10% or furnished at 12% or housing allowance of 20% of pensionable salary. Up to five full economy passages on appointment and on normal termination. Study and Travel Grant.

Detailed applications giving qualifications and experience and naming three referees to the Campus Registrar, University of West Indies, St Augustine, Trinidad, West Indies. Details of post sent to all applicants, but also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1902)A

CANCER RESEARCH

The AMC Cancer Research Center seeks to expand its laboratory and clinical research programs. Individuals at all levels, from Post-doctoral Fellows to Department Chairmen, will be considered. Current interests include tumor cell biology, tumor immunology, experimental hematology, monoclonal antibodies, cell kinetics, nucleic acid metabolism, nuclear magnetic resonance imaging, as well as clinical and national community research and control programs. Scientists (Assistant Professor equivalent) will be expected to vigorously develop independent research. Senior Faculty must be of national prominence and hold significant external funding. Opportunities exist for collaboration and growth. Facilities, equipment and initial research support are available. Clinical resources on campus include a 32 bed inpatient unit, outpatient clinics and services. Individuals with interests bridging laboratory and clinical cancer research are particularly sought. Send Curriculum vitae and other pertinent information to:

Dr. Philip Furmanski
Associate Director
AMC Cancer Research Center
1600 Pierce Street
Denver, Colorado 80214

(NW1798)A

UNIVERSITY OF THE WEST INDIES MONA, JAMAICA

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the following posts in the University of the West Indies

LECTURER/ASSISTANT LECTURER

It is desirable for teaching purposes that the successful applicant should have a broad training in Biochemistry. Certain areas of research interest are particularly welcome, eg plant biochemistry, toxicology, nutrition, immunology, biotechnology. Duties to be assumed as soon as possible.

Salary scales (under review): Lecturer (non-medical) J$23,688 × 768 - 28,296 (B) × 825-33,246. Assistant Lecturer (non-medical) J$20,379 × 717-21,813.

Up to five full economy class passages plus baggage allowance up to US$900 on appointment and normal termination. Special allowance up to US$900 on appointment and normal termination. Special allowance up to US$300 for shipment of academic books and teaching/research equipment on appointment. Unfurnished accomodation at 10% of pensionable salary or housing allowance of 20% of pensionable salary. UWI contribution of equivalent of 10% of salary to Superannuation Scheme. Subsidized Health Service. Annual Book Allowance. Annual Study and Travel Grant for self, spouse and three children. Transportation allowance to persons who own and operate a motor vehicle.

Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status, and the names and addresses of three referees should be sent as soon as possible to the Campus Registrar, UWI, Mona, Kingston 7, Jamaica. Applicants in the UK should also send one copy to the Assistant Secretary General (Appointments), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. Further details obtainable from either source. (W1905)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
London W1P 6DB
(University of London)

DEPARTMENT OF ANATOMY AND BIOLOGY AS APPLIED TO MEDICINE

POST-DOCTORAL RESEARCH ASSISTANT 1A

Applications are invited for this SERC supported post, tenable from October 1, 1985 (or earlier), to work for 3 years on cell contact and movement using advanced fluorescence methods.

Written applications, including the names of two referees, should be sent to Professor D Gingell at the above address. (6650)A

TECHNICAL UNIVERSITY OF GRAZ, AUSTRIA

The Chemistry Department of the Technical University of Graz invites applications for the position of a

FULL PROFESSOR OF PHYSICAL CHEMISTRY

at the Institute of Physical and Theoretical Chemistry. Applicants are expected to be internationally recognized researchers having appropriate teaching experience to teach the full course program of Physical Chemistry. Willingness to cooperate with existing research groups at the institute (crystal structure, theoretical chemistry, spectroscopy and magnetochemistry, solid-state chemistry, quantum chemistry) and interest in interdisciplinary team work is expected. Candidates are asked to send their resume (curriculum vitae, teaching experience, list of publications etc) and reprints of five of their most important publications.

Application deadline is September 16, 1985. Submit your application and resume to: Dekan der Technisch-Naturwissenschaftlichen Fakultät der Technischen Universität Graz, Petersgasse 16, A 8010 Graz, Austria, where also additional information may be requested. (W1891)A

UNIVERSITY OF CALIFORNIA

DEPARTMENT OF PHYSICS

ENDOWED CHAIR PROFESSOR OF PHYSICS

The UCLA Physics Department has an open Endowed Chair position. An appointment will be considered in any field of experimental or theoretical physics. The successful candidate will have a regular University of California tenured faculty position; the endowment income will support the candidates' program.

The successful candidate will be expected to lead an internationally recognized research program, and to teach at the graduate and undergraduate level.

Applicants should send a curriculum vitae, a brief statement of past, present, and future research interests, and the names of 5-10 referees to C Kennel, Chair, Department of Physics, University of California, Los Angeles, CA 90024.

The department is especially interested in identifying women and minority candidates.

The University of California is an affirmative action/equal opportunity employer. (NW1435)A

UNIVERSITY OF SOUTHAMPTON

CHAIR OF OCEANOGRAPHY

Applications are invited for the Chair of Oceanography which will become vacant on the retirement of Professor H Charnock, FRS, on 30 September 1986. Applicants should have research interests in the physically-related marine sciences and the ability to foster work in a multi-disciplinary field.

Further details may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH, to whom applications (10 copies from persons in the UK) should be sent before 12 July 1985. (6626)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF PHYSIOLOGY

RESEARCH ASSISTANT

Applications are invited for the above post, tenable for up to three years, to work on a project concerned with thermal changes in the immersed human body. This phase of the work is a theoretical study and will involve mathematical modelling. Applicants should have, or expect to get, a good honours degree, ideally with some experience of modelling biological systems but ability and enthusiasm could offset lack of experience.

Salary within range £6,600 — £7,520 on the 1B Scale for Research and Analogous Staff, with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University Aberdeen, with whom applications (2 copies) should be lodged by 28 June 1985. (6622)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following position:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF DEVELOPMENTAL BIOLOGY

POSTDOCTORAL FELLOW - MOLECULAR ANALYSIS OF DEVELOPMENT PROJECT

A Postdoctoral Fellow is required in the Department of Developmental Biology for a project on genetic analysis of events in the cell cycle of Chlamydomonas. A background in genetics, biochemistry and ultrastructural analysis would be advantageous. The position will commence on 1 January 1986.

Further particulars can be obtained from Professor B Gunning, Head of Department (062) 49 2372, or from Dr P C L John (address until 31 July 1985, Department of Botany, Queen's University of Belfast, Belfast BT7 1NN, UK).

Closing date: 31 July 1985. Ref: BS 15/5/1.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow $A22,614 - $25,905 pa.

Appointment, unless otherwise stated, will be: Postdocotral Fellow normally two years, with the possibility of extension to maximum of three years.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote the advertisement reference when requesting further particulars, and when submitting applications, which should be sent to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. Further information also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The University is an equal opportunity employer. (W1904)A

POSTDOCTORAL POSITION

Is available immediately to study functional role of insulin in the brain at the cellular level with Drs. D.W. Clarke and M.K. Raizada. Experience in cell culture and biochemical techniques is a disirable. Experience with immunocyto-chemistry would be helpful. **Contact Dr. Mohan K Raizada, Dept of Physiology, J274, Univ of Fla Gvl, FL 32610 or telephone 904 392-3791.**

(NW1802)A

AFRC FOOD RESEARCH INSTITUTE — BRISTOL

LANGFORD,
BRISTOL BS18 7DY

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER (85/17)

ASSISTANT SCIENTIFIC OFFICER (85/19)

SHORT TERM CONTRACTS (3 YEARS)

Applications are invited for 2 short term contracts (3 years) to examine gaseous forms of preslaughter anaesthesia in pigs and poultry. The project is aimed at resolving some of the humanitarian problems associated with the slaughtering of livestock.

Salary SO/HSO £5,909 — £10,039. ASO £4,456 — £6,315.

Qualifications SO/HSO (Post 85/17) Degree in a Biological Science with relevant post-graduate research experience.

ASO (Post 85/19) HNC in Biology.

Further particulars and an application form from the Personnel Officer at the above address.

The Agricultural and Food Research Council is an equal opportunities employer. (6649)A

UNIVERSITY OF GLASGOW

DEPARTMENTS OF BIOCHEMISTRY AND PHARMACOLOGY

WELLCOME LECTURESHIP IN MOLECULAR PHARMACOLOGY

Applications are invited for a Wellcome Lectureship in Molecular Pharmacology to be held jointly in the Departments of Biochemistry and Pharmacology. The appointment will be for three years: it may be renewed for a further two years subject to satisfactory progress. Applicants should not be more than 35 years of age and persons having a permanent University post in the UK are ineligible.

The successful applicant will contribute to the teaching in both departments and in research will become part of an active interdepartmental group. The departments are in the process of appointing a 'New Blood' lecturer to the same group.

The salary will be within the range of £7,520 — £14,925 per annum of the Lecturer's scale, with placement according to age, qualifications and experience.

Those wishing to be considered should send eight copies of a statement of their qualifications and experience, including a list of publications and the names and addresses of not more than three persons to whom reference may be made, to Professor R M S Smellie, Department of Biochemistry, University of Glasgow, Glasgow, G12 8QQ, not later than 21st June, 1985, from whom further particulars may be obtained. The applications must be accompanied by a summary of not more than 500 words outlining the proposed research. (6666)A

HEINRICH-PETTE-INSTITUT FÜR EXPERIMENTELLE VIROLOGIE UND IMMUNOLOGIE

AN DER UNIVERSITÄT HAMBURG

Applications are invited for the Tenure Position of

HEAD OF DEPARTMENT OF MOLECULAR BIOLOGY

Candidates with extensive scientific experience are expected to lead a research group in the general field of molecular biology. Budget and tenure positions are available. The Heinrich-Pette-Institut is an independent research establishment, active in the fields virology, immunology, and cell biology. Administrative experience and willingness to participate in running affairs of the institute are required. Teaching at the University of Hamburg is on voluntary basis. The salary is according to BAT I and depends on age and family status.

Applications including curriculum vitae and list of publications should be sent: An das Direktorium, Heinrich-Pette-Institut, Martinistraße 52, D-2000 Hamburg 20, Federal Republic of Germany. Closing date 31 August 1985. (W1892)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)

DEPARTMENT OF ENTOMOLOGY

LECTURER OR SENIOR LECTURER

Applications are invited from medical entomologists for a tenured post in the Entomology Department. Preference will be given to applicants combining tropical experience with an outstanding record in research, preferably in biochemistry, ecology, population dynamics, or insect behaviour, but experience in any field within entomology applied to human health will be considered.

The person appointed will be expected to develop active research programmes, with overseas connections, and the extensive facilities of the London School will be available for this.

Appointment will carry a salary in the range £8,753 to £18,938 (inclusive of London Weighting) on the Universities' Lecturer or Senior Lecturer scale according to age, qualifications and experience, with membership of USS.

Further information may be obtained from Professor A N Clements (01-636 8636 ext 348). Applications with full curriculum vitae and the names of three referees should be sent to the Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT.

Closing date: 5 July 1985. (6635)A

We are a major Italian pharmaceutical company with a growing interest in biotechnology.
We are looking for an experienced

BIOCHEMIST/ IMMUNOCHEMIST

For a newly created laboratory of biochemistry and immunology, located in the urban area of Milan, Italy.

Potential candidates should have a doctorate degree and post-doctoral training. Previous experience in hybridoma technology for diagnostic purposes would be considered an advantage.

We Offer:
- career opportunities based on performance;
- a competitive salary in accordance with experience and qualifications;
- a stimulating, dynamic work environment;
- assistance in relocation expenses.

Candidates from EEC Countries are encouraged to apply.

Please contact in confidence:
P.O. Box 10119
Personnel Dept.
20110 Milan, Italy (W1898)A

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY

(University of London)

HAMMERSMITH HOSPITAL

RESEARCH ASSISTANT

Applications are invited for the post of research assistant for up to 3 years to work on arachidonic acid metabolism in fetal growth retardation. Candidates should have or expect to obtain a 1st class or upper 2nd class honours degree in Biochemistry. The successful applicant will be expected to register for a PhD in London University.

Further information from and applications to Professor M G Elder Institute of Obstetrics and Gynaecology, Hammersmith Hospital, Du Cane Road, London W12 0HS. (6633)A

THE UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

BIOCHEMISTRY LABORATORY

WELLCOME LECTURESHIP IN BIOCHEMISTRY

Applications are invited for the Wellcome Lectureship in Biochemistry. Applicants should have research experience, preferably in the area of the biochemistry of secretion of polypeptide hormones, growth factors or neuropeptides. Those holding tenured positions are not eligible for consideration, and applicants should not normally be over 35 years in age.

Appointments will be for 3 years in the first instance, renewable for a further 2 years, subject to a satisfactory review. The salary will be on the University Lecturer scale (£7,520 to £14,925 pa).

Send self addressed envelope (6" x 9") for further particulars and an application form to Mrs L Vivian, Personnel Office, Sussex House, The University of Sussex, Falmer, Brighton BN1 9RH, Sussex. Closing date for applications 10th June 1985. (6629)A

UNIVERSITY OF BATH

SCHOOL OF CHEMISTRY

POST DOCTORAL RESEARCH OFFICER

Applications are invited for a Research Officer to work with Dr S Mann for three years beginning October 1985 to investigate the structural and mechanistic properties of magnetic solids formed in bacteria. Applicants should have a strong interest in structural inorganic chemistry and have some experience in electron microscopy and electron diffraction.

Starting salary up to £7,980 pa (under review).

Application forms from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting ref no: 85/79. Closing date: 13/6/85. (6619)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY PATHOLOGY

MOLECULAR VIROLOGY UNIT

A molecular virology unit has been established to develop novel vectors for the expression of viral antigens in mammalian systems. This unit works in close collaboration with virologists and molecular biologists in this department and at the Beatson Institute.

Three positions, supported by the National Institutes of Health, are immediately available. Applications are invited for 2 post-doctoral fellows (salary range £8,450 to £10,720 per annum) and a research assistant (£6,600 per annum). The research assistant may apply to register for a higher degree.

The applicants should have experience in recombinant DNA technology and a background in virology would be an advantage. Applications should be sent to, and further particulars may be obtained from, Professor W F H Jarrett, FRS, University of Glasgow, Veterinary School, Bearsden, Glasgow, G61 1QH (telephone number 041-942-2301). (6658)A

BIOTECHNOLOGISTS!

What's going on in the world's fastest-growing scientific discipline?

To find out, send for a sample copy of BIO/TECHNOLOGY, the International Monthly for Biology and Industry, to

Felicity Parker, Macmillan Journals, Houndmills, Basingstoke, Hants. RG21 2XS, UK

or

Paul Siman, Bio/Technology, 65 Bleecker St., New York, NY 10012.

MOLECULAR BIOLOGIST

Applications for an assistant professorship are invited from individuals with major commitment toward research and whose interests are in the structure, regulation or expression of viral, or mammalian, genes. Expertise in genetic engineering of enzymology-protein chemistry, an asset. Knowledge of or readiness to learn French essential. Send applications to: Dr Pierre Bourgaux, Directeur, Département de Microbiologie, Faculté de Médecine, Centre Hospitalier Universitaire, Université de Sherbrooke, Sherbrooke, Québec, Canada J1H 5N4.

(NW1790)A

CHARING CROSS AND WESTMINSTER MEDICAL SCHOOL

(University of London)

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

required to investigate the organisation of Campylobacter DNA, particularly the structure and expression of toxin genes. Previous experience, preferably postdoctoral, in prokaryotic molecular genetics and recombinant DNA techniques is essential. Experience with expression vectors is desirable. The successful applicant will join a group working on various applications of molecular biology to clinical problems.

The post is available immediately for a fixed term period of up to three years. Salary will be on Scale 1A for Research and Analogous staff, (£7,520 — £12,150 pa) at a point appropriate to age and experience plus £1,233 pa London Allowance.

For further information concerning the project or the department, telephone Dr L Archard, 01-741 1858.

Applications on forms obtainable from The Secretary, Charing Cross and Westminster Medical School, The Reynolds Building, St Dunstan's Road, London, W6 8RP, to be submitted within three weeks of the appearance of this advertisement.

(6625)A

UNIVERSITY OF LONDON

RANK CHAIR OF PHYSIOLOGICAL BIOCHEMISTRY TENABLE AT IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

The Senate invite applications for the above Chair, tenable in the Department of Biochemistry at Imperial College of Science and Technology.

Candidates should have demonstrated an interest in cellular biochemistry and/or control of integrated physiological processes. They should have significant research accomplishments and an interest in the teaching of these aspects of biochemistry in advanced undergraduate courses.

Applications (10 copies) must be received not later than 15 July 1985 by the Academic Registrar (N.), University of London, Malet Street, London WC1E 8HU, from whom further particulars should first be obtained.

(6631)A

NEUROENDOCRINE RESEARCH GROUP

DEPARTMENT OF ANATOMY

UNIVERSITY OF CAMBRIDGE

We are seeking a postdoctoral physiological psychologist, or relevantly qualified zoologist or clinical graduate to join a multidisciplinary research tea investigating the neuroendocrine basis of social behaviour and anxiety in an experimental setting. The position is funded by the MRC and available immediately; the initial appointment is for 1 year, renewable for up to 5 years in total.

Please send applications (including CV) to Mrs J Penton, Department of Anatomy, University of Cambridge, Downing Street, Cambridge CB2 3DY by July 1st, and arrange for references to be sent direct from 2 referees.

(6686)A

THE ANIMAL VIRUS RESEARCH INSTITUTE

POST-DOCTORAL MOLECULAR BIOLOGIST

Applications are invited for a 3 year appointment to work on analysis of the genome structure of classical swine fever (hog cholera) virus and its relationship to bovine virus diarrhoea. The work will involve molecular cloning of the genome RNA and nucleotide sequence determination. The successful applicant will work with Dr Charles Penn in the Division of Molecular Biology. He/she should have a degree in biochemistry, microbiology or a related subject and a PhD. Experience in gene cloning would be an advantage.

The salary will be in the scale of £7,435 - £10,039 (Higher Scientific Officer grade) pay award pending. Sick leave and non-contributory superannuation schemes, 22 days annual leave. Accomodation may be available. The AVRI is an equal opportunity employer.

Application to include a curriculum vitae and the names of two referees should be sent as soon as possible to the Secretary, Animal Virus Research Institute, Ash Road, Pirbright, Woking Surrey GU24 0NF. Tel: 0483 232441. (6640)A

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF BIOCHEMISTRY

TEMPORARY LECTURESHIP

A vacancy exists for a Temporary Lecturer as a result of Dr J R Burton being awarded a five-year Research Fellowship by the Lister Institute. Candidates with research interests in any area of Biochemistry are eligible to apply for preference may be given to those with experience of recombinant-DNA technology or immunology. It is expected that the successful candidates will be appointed for a period of three years with the possibility of extension for a further two years.

Salary within the range £7,520 — £11,675 on the non-clinical lecturers salary scale.

Applications including the names of three referees should be sent to the Personnel Department (Academic Staffing), the University, Sheffield S10 2TN by 14 June 85 from whom further particulars are available. Quote ref: R275/G (6617)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

RESEARCH ASSISTANT

Applications are invited for the above post, tenable immediately for up to two years, to work on the isolation of cNDA clones for the structural glycoprotein present in human aorta. A range of microbiological, immunological and gene cloning techniques will be involved. Applicants should have an honours degree in an appropriate discipline.

The appointment is funded by the Maitland Ramsay Trust. Starting salary within the range £6,600 to £7,980 per annum (under review) according to age and experience, on the 1B scale, plus USS.

Further information can be obtained by writing or by telephone from professor Serafini-Fracassini (tel 0334-76161, ext 275).

Applications (2 copies preferably in typescript) enclosing a full curriculum vitae and the names of 2 referees should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ to arrive not later than 20 June 1985.

(6661)A

UNIVERSITY OF OXFORD

DEPARTMENT OF NUCLEAR PHYSICS

APPOINTMENT OF RESEARCH OFFICER

The department will shortly appoint a Research Officer in Particle Physics. Whilst mainly a research appointment, the appointee will be required to undertake seventy-two hours a year of laboratory demonstrating and he/she will be encouraged to give graduate lectures. The research programme of the experimental particle physics group includes the Soudan II search for proton decay, a major contribution to the DELPHI detector for LEP (CERN), preparation for an experiment at HERA (DESY), and development of an indium detector for solar neutrinos.

The appointment will be for three years with possible extension to five years. Salary will be on the Lecture scale £7,520 - £15,930 (under review).

Applications with the names and addresses of two referees should be sent to Mr M S Gautrey, Department of Nuclear Physics, Keble Road, Oxford from whom further particulars may be obtained. The closing date is September 5th 1985.

(6676)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY DIVISION OF IMMUNOLOGY

SCIENTIST

A Scientist with a post-graduate qualification in Biochemistry or Organic Chemistry is required to join in a project investigating the development of immunoassay systems using red cell-labelled antibodies. Experience in protein chemistry or immuno-chemistry desirable. The appointment is for two years in the first instance, possibilities of an extension.

Enquiries to Professor R R A Coombs, Division of Immunology, New Adenbrooke's Hospital, Hills Road, Cambridge. Tel Cambridge 0223 245171 ext 336. Age up to 30

Salary range: University scales age related.

Formal applications together with curriculm vitae and the names and addresses of two referees to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. (6667)A

UNIVERSITY OF LEICESTER/DARESBURY LABORATORY

POST-DOCTORAL RESEARCH ASSOCIATE IN EXPERIMENTAL X-RAY DIFFRACTION AT HIGH PRESSURES

Applications are invited for the above post, funded by SERC, tenable from 1st October 1985, or as soon as possible thereafter, for up to three years.

The successful candidate will be expected to pursue research at the Synchrotron Radiation Source at Daresbury into structural changes in solids at very high pressures, on the newly commissioned Power Diffraction Station on the Wiggler beam line. The project involves application of novel high-resolution powder diffraction techniques to materials at very high pressures, and is backed by a major theoretical programme of molecular dynamics simulations.

Applicants should hold a PhD in experimental science. Experience with X-ray or neutron crystallography, and computing would be an advantage. The starting salary will be in the range £7,520 to £8,450 according to age and experience.

Applications, together with a full curriculum vitae and the names of two referees to Dr D M Adams, Department of Chemistry, University of Leicester, Leicester LE1 7RH by 15th July 1985. (6682)A

SANDWELL HEALTH AUTHORITY

The Midland Centre for Neurosurgery and Neurology

DEPARTMENT OF PATHOLOGY

ELECTRON MICROSCOPIST

in charge of Section

(Basic/Senior Science Graduate)

required on a Locum basis (available grading up to Senior as defined by Whitley Council PTA regulations). Well housed department with two other staff, two Siemens microscopes, several ultramicrotomes. Successful applicant will be required to continue and develop service in Muscle, Central and Periperal Nervous System Pathology, to Hospital and Region. Collaboration with current research projects will be expected and there is an excellent opportunity to develop a personal research programme on the readily available material.

Intending applicants are welcome to visit by appointment with Dr M V Salmon (Neuropathologist) - 021-558 3232 ext 314.

Job description and application form from the Administrator, Midland Centre for Neurosurgery and Neurology, Holly Lane, Smethwick, Warley, West Midlands B67 7JX. Tel: 021-558 3232 ext 251. (6677)A

Cell Biologist/Biochemist/ Neurobiologist

Postdoctoral research position is immediately available for PhD with experience in cell biology, biochemistry, or neurobiology to investigate hereditary neuromuscular disorders. Initial research will focus on mechanisms of regulation of cell growth and the developmental expression of surface proteins in nerve, muscle, and related tissues. Applicants should have a PhD and experience in: cell biology and biochemistry; culture of nerve, muscle and fibroblasts; immunological methods for the study of cell proteins. Extensive possibilities exist for collaboration with expert neuromuscular morphologists and with active molecular genetics/recombinant DNA laboratory. Excellent support; salary commensurate with experience. Direct inquiries to: Dr. Robert H. Brown, Jr., Day Neuromuscular Research Center, Massachusetts General Hospital Warren 370/374, Boston, MA 02114. (NW1792)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

ENDOCYTOSIS

A post-doctoral research assistant is required to work on a cell-free assay for studying the pathway of adsorptive endocytosis. The aim is to understand the molecular basis of this process. Preference will be given to candidates with training in membrane biochemistry and/or enzymology.

This project is funded by the MRC and the position is for three years commencing 1st January 1986. The salary will be in the range £7,520-£12,150 per annum.

Applications, including a curriculum vitae, research summary and the names and addresses of three referees, should be sent to the Personnel Officer, The University, Dundee, DD1 4HN, Scotland as soon as possible. Informal enquiries concerning this project should be addressed to Professor Graham Warren, who is presently at the European Molecular Biology Laboratory, Postfach 10 2209, 6900 Heidelberg, West Germany. Tele phone number 010 49 6221 387324. Please quote Ref EST/66/85J. (6466)A

RESEARCH ASSOCIATE POSITION

Opportunity exists to work on a project concerned with the biochemical mechanisms of hormone (insulin) action to control phosphorylation and redox state. Applications are invited from qualified candidates with a Ph.D. or M.D. degree. Submit a resume of research interests, curriculum vitae and three letters of recommendation to Dr. Joseph Larner, Department of Pharmacology, Box 448, University of Virginia School of Medicine, Charlottesville, Virginia 22908. An affirmative Action/Equal Opportunity Employer. (NW1812)A

AGROGEN BIOTECHNOLOGIES SENIOR SCIENTISTS — PLANT TISSUE CULTURE

Agrogen Biotechnologies Inc., a Vancouver, BC based Canadian company interested in plant tissue culture, micropropagation of woody ornamentals and forest tree species and related biotechnologies is seeking Senior Scientists in plant tissue culture to provide project leadership and research support to its micropropagation program.

The positions require a PhD with a strong background in plant physiology, cell biology, genetics or biochemistry with several years research experience in plant tissue culture. Agrogen offers the opportunity to join an energetic interdisciplinary research team, excellent research facilities, competitive salary and fringe benefits.

Please forward your curriculum vitae and other pertinent information in confidence to: Dr. D. Paul Webb, Director of Research, Agrogen Biotechnologies, Inc. 1710-1066 West Hastings Street, Vancouver, BC V6E 3X2. (NW1793)A

THE UNITED MEDICAL AND DENTAL SCHOOLS

ST THOMAS'S CAMPUS

RESEARCH ASSISTANT

(post-doctoral)

required to work on project on the role of Coxsackie-B Viruses in the pathogenesis of insulin-dependent diabetes mellitus (type 1).

Sound virological experience essential; experience with such techniques as ELISA, monoclonal antibody production and PAGE an advantage. Funding is being sought for one year appointment from 1 September 1985 in the first instance. Salary not less than £7,520 plus £1,233 LWA pa (grant application pending).

For further information, contact Professor J E Banatvala, Dept of Virology, tel: 01 928 9292 ext 2405.

Applications giving full cv and names and addresses of 2 referees to Staffing Officer, Dean's Office, St Thomas's Hospital Medical School, London SE1 7EH by 13 June 1985. (6664)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF GEOLOGY

POST-DOCTORAL/ POST-GRADUATE RESEARCH ASSISTANT IN SEISMOLOGICAL COMPUTING

To work on the acquisition, digitisation processing and interpretation of the data from an international seismic refraction experiment to be carried out in Kenya in August 1985. The data processing will require the development, maintenance and operation of Fortran 77 programmes on VAX 11/70-8600 system. The appointment will be for two years from July 1985 with a salary of £6,600 — £7,055.

Applications, including a CV and the names of two referees, should be sent by June 7 to Dr M A Khan, Department of Geology, The University, Leicester LE1 7RH from whom further particulars may be obtained. (6641)A

UNIVERSITY COLLEGE LONDON

RESEARCH TECHNICIAN

Grade 4

Cell Biology

Applications are invited for the above post to assist in the development of a new project on the intracellular transport of membrane proteins, funded for 3 years by the MRC.

The person selected to join our small friendly group will have an interest in research and be qualified to at least HNC standard. Experience with tissue culture, cell fractionation or protein purification would be an advantage.

Salary £6,106 — £6,837 + £1,250 London Weighting.

Applications, including CV and the names of 2 referees should be sent to Personnel Officer (Technical Staff GE6), University College London, Gower Street, London WC1E 6BT. (6651)A

ROYAL HOLLOWAY AND BEDFORD COLLEGES

RESEARCH ASSISTANT

Applications are invited from Physicists, Engineers or Applied Mathematicians, to join a team engaged in a range of projects on fundamental aspects of Electromagnetic Antennas for Millimetric Wavelengths. This project involves both theoretical work (using analytical and computational techniques) and supporting experimental studies in one or more of the following areas:-

(1) Electromagnetic Theory
(2) Numerical Control Engineering
(3) Applied Optics

Candidates should have an aptitude for research and a good degree or a postgraduate qualification in a relevant subject. Salary scale £9,863 — £11,093 (under review).

Applications (2 copies) with curriculum vitae and names and addresses of 2 referees should be sent immediately to the Personnel Officer, Royal Holloway and Bedford Colleges, Egham Hill, Egham, Surrey TW20 0EX. (6648)A

FACULTY POSITION

The Psychology Department of the Massachusetts Institute of Technology announces the opening of a faculty tenure-track position in neuroscience. Applicants with a PhD or equivalent degree are sought with training and research background in mammalian brain-morphology and function.

Interested applicants should send a letter of inquiry with curriculum vitae and three references by July 31, 1985, to:

Dr. Peter H. Schiller
Psychology Department
Search Committee
Massachusetts Institute of Technology, E25-634
77 Massachusetts Ave.
Cambridge, MA 02139.

Qualified minorities and women are encouraged to apply. MIT is an affirmative action/equal opportunity employer. (NW1791)A

MIT

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF PHYSIOLOGY

WELLCOME LECTURESHIP

Applications for the above post are invited from candidates in the field of neuroscience with expertise and interest in pursuing research involving the use of an in-vitro brain slice. Candidates wishing to visit the department or make provisional enquiries should contact Professor A M Sillito (0222)-44211 ext 2062.

Candidates should be less than 35 years old and must not currently hold a permanent university appointment. The post is tenable for five years (subject to a review after three years) and should commence on the 1st October 1985, although this date could be negotiated for a suitably qualified date. Appointment will be made at the appropriate point on the lecturer scale (scale is £7,520-£14,925).

Applications (three copies) with curriculum vitae, 500 word synopsis of the proposed research and the names and addresses of three referees should be forwarded to the Vice-Principal (Administration) and Registrar, University Coilege, P O Box 78, Cardiff CF1 1XL from whom further particulars may be obtained. Closing date 24th June 1985. Reference: 2967. (6678)A

UNIVERSITY OF DUBLIN
Trinity College

TEMPORARY LECTURER IN ZOOLOGY

Applications are invited for the above post in the Department of Zoology at Trinity College, Dublin. The appointment will be tenable from 1st October, 1985 for one year, and may be renewed for a further year. Preference will be given to candidates having interests in Invertebrate Reproduction.

Salary: IR £9,302 per annum.

Application forms and further particulars relating to this appointment may be obtained from.

Establishment Officer
Staff Office
Trinity College, Dublin 2
Tel: 772941 Ext 1775

to whom completed application forms should be returned by **not later than Tuesday, 11th June, 1985.** (6638)A

UNIVERSITY OF ZUERICH
DEPARTMENT OF PHYSIOLOGY
A MOLECULAR BIOLOGIST

is required for a three year postdoctoral position, to work on the regulation of mRNA by oxygen availability in cultured kidney cells. Applicants should have PhD or equivalent in Biochemistry/molecular Biology and a minimum of two years of postdoctoral experience in these areas. Knowledge in cell culture techniques would be an advantage. Salalry in range sFr. 47.000-60.000/yr, depending on experience and qualification. The position is available now, starting date to be agreed.

Application with the names and addresses of two referees should be sent to Professor C. Bauer, Dept. of Physiology, University of Zuerich, Winterthurerstr. 190, 8057 Zuerich, Switzerland. (W1894)A

PROFESSOR & HEAD
Biological Sciences
Carnegie-Mellon University

The Department of Biological Sciences invites applications from qualified individuals to serve as Professor and Chairperson. We seek an individual with an established reputation in any field of biological research and an ability to provide leadership in the continuing growth of this department. We expect to appoint the successful candidate by 30 June 1986 or before

Applications or inquiries should be sent to Professor W.R. McClure, Chairman, Search Committee, Carnegie-Mellon University, 4400 Fifth Ave., Pittsburgh, PA 15213.
Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer.

CONFERENCES and COURSES

UNIVERSITY COLLEGE, LONDON:
SCHOOL OF MEDICINE

PART TIME COURSE IN TOXICOLOGY

A course in toxicology consisting of lectures and practical classes will be given weekly for 30 weeks, on Wednesdays at 15:45-19:00 hrs, starting on 2nd October 1985.

A broad treatment of topics in toxicology will be presented, including basic histopathology, biochemical and genetic aspects and methodology. Regulatory aspects of toxicology will also be discussed. The course is intended (1) for graduates with some experience in a relevant field; (2) for postdoctoral and other scientists wishing to broaden their knowledge of toxicology.

The fee for the 30 week course is £600. Numbers will be restricted to a maximum of 25 participants. Some assisted places where all or part of the course fees are waived are available to suitable applicants whose fees are not paid by their employer (e.g. persons working in Universities or similar institutions and holding non-tenured posts). Further details and application forms may be obtained from: —

Dr. I.C. Shaw
Toxicology Laboratory
Department of Clinical Pharmacology
University College London
5 University Street
London WC1E 6JJ, England
(01) 388-2411 Ext 212

Closing date for applications — 1st July 1985. (6656)C

Royal Postgraduate Medical School
(University of London)

A specialist scheme of study for graduates in medicine and biology leading to the award of:

DIPLOMA in ENDOCRINOLOGY

This is a one academic year, full-time, intensive laboratory-based training course open to graduates in medicine and biology who wish to develop skills in modern endocrinological investigative methods. The selected applicants, who must be experienced in light or electron microscopical morphology, biochemistry or a related discipline, will undertake a series of research projects during their training period in recognised laboratories within this Medical School. Award of the Diploma will depend on successful completion of an examination or by thesis.

Further details and application forms may be obtained by writing to:

The School Office, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS.

Completed application forms must be received before 31 July 1985 for registration on the 1985-86 Diploma course (6681)C

GRANTS and SCHOLARSHIPS

Research Award in Immunoregulation

Centocor, Inc., will award a $10,000 unrestricted research grant for the most outstanding human Interferon-Gamma scientific paper published (or accepted for publication) between 1/1/85 and 6/30/86.

For details, write to Centocor customer service.

WORKSHOP

ST JOHN'S COLLEGE CAMBRIDGE

α-1-ANTITRYPSIN MOLECULES AND MEDICINE

8-11 September 1985

Guest Chairman Professor C-B Laurell Sweden.

An international workshop to sumarise progress and define goals in research and clinical management.

Enquiries: Professor R W Carrell St John's College, Cambridge CB2 1TP UK. (6477)V

FELLOWSHIPS

THE UNIVERSITY OF SHEFFIELD

Faculty of Medicine

J G GRAVES MEDICAL RESEARCH FELLOWSHIP

Applications are invited for the above Fellowship tenable for a period of three years from 1 October 1985. The Fellow will be required to undertake full-time medical research in one of the medical or dental departments or hospital. Initial salary according to qualifications and experience within the range £7,520 — £8,920 a year, a higher salary may be offered to a candidate with appropriate experience and seniority. Additional funds may be available for the Provision of laboratory assistance and materials.

Further particulars from the Personnel Department (Academic Staffing), the University, Sheffield S1Q 2TN to whom applications (10 copies), including the names and addresses of three referees, indicating the line of research proposed), should be made by 17 June 1985. Quote refs R269/G. (6665)E

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

supported by the British Gas Corporation. The work will be concerned with "Development of Membranes with Improved Selectivity" and will be directed mainly towards synthesis of novel polymers suitable for fabrication into membranes showing improved selectivity in gaseous diffusion processes combined with high stability at elevated temperatures.

The post will initially be for one year with a salary of up to £8,920 per annum depending on age, qualifications and experience. Superannuation is under USS conditions.

Applications are invited in the form of a curriculum vitae (3 copies) including the names and addresses of two referees, and should be sent to the Personnel Office (JLG), University of Surrey, Guildford, Surrey GU2 5XH as soon as possible, quoting reference 75. (6646)E

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Cell Culture of Marine Algae

Applications are invited for a Post-Doctoral Research Fellowship funded by the University of Aberdeen to work with Drs S B Wilson, F B Williamson and W F Long. The project will involve the development of continuous cultures of marine red algal cells primarily to produce materials with commerical value.

The post has initially been funded for one year but scope exists to obtain further financial support giving an appointee with flair and imagination a chance to share in the longer term future of this exciting new field. Applicants should preferably have a PhD and some experience in cell culture.

Salary on Range 1A Scale for Research and Analogous Staff up to £8,920 per annum, with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by 30 June 1985. (6668)E

POSTDOCTORAL FELLOWSHIP

In Molecular Biology/Biochemistry Position available Sept. 1, 1985 in Department of Microbiology at SUNY Stony Brook to study adeno-associated virus genetics, vector construction immunology or DNA replication. Send CV and references to Dr. Nicholas Muzyczka, University of Florida, College of Medicine, Box J-266 JHMHC, Gainesville, Florida 32610. (NW1797)E

POSTDOCTORAL FELLOWSHIP POSITIONS

Molecular Biology

Well-established cardiovascular research laboratory studying the molecular biology of lipoproteins and receptors is seeking molecular biologists with experience in cloning and DNA sequencing.

Candidates with a Ph.D. in molecular biology or biochemistry are eligible.

Send curriculum vitae and three letters of reference to: Personnel, c/o Dr. Brian McCarthy, The Gladstone Foundation Laboratories for Cardiovascular Disease, University of California, San Francisco, P.O. Box 40608, San Francisco, CA 94140-0608.

(NW1803)E

POSTDOCTORAL FELLOWSHIPS

California Biotechnology Inc. invites applications from recently qualified Ph.D.'s to join its postdoctoral research program. CBI is an established biotechnology company located in the Palo Alto area forty miles south of San Francisco. The company, which has about eighty scientific employees, is dedicated to applying the techniques of molecular biology, protein chemistry and cell biology to develop novel human and veterinary pharmaceuticals. It currently has major research programs in hypertension, atherosclerosis, inflammation, lung disease, reproductive biology, growth factors and polypeptide hormones. Recent graduates, who have experience in areas such as recombinant DNA technology, protein and peptide chemistry, cell biology and pharmacology, would join established research teams in one of the above areas. The postdoctoral fellowship would for a minimum of two years.

(NW1800)E

Please send applications, including a complete curriculum vitae to:

CBI

Dr. John Shine
Director of Research
California Biotechnology Inc.
2450 Bayshore Frontage Road
Mountain View, CA 94043

ESF PROGRAMME OF RESEARCH FELLOWSHIPS IN TOXICOLOGY

Short-term (up to 6 months) and Long-term (6-12 months) Research Fellowships (deadline: 30 September 1985) and Short-term (up to 1 month) Visiting Fellowships (no deadline) are offered to scientists working in European countries. No formal condition of age, level or field of training, provided the project contributes to furthering research in TOXICOLOGY in Europe. Information and application forms can be obtained from: Dr John Smith, European Science Foundation, 1, quai Lezay-Marnésia, F-67000 STRASBOURG, France; tel (88) 35 30 63; telex 890440. (W1890)E

EMBO
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
Autumn 1985 — Awards
Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R. Germany.

(W1893)E

STUDENTSHIPS

THE POLYTECHNIC OF CENTRAL LONDON

Faculty of Engineering & Science

RESEARCH POSTS IN THE SCHOOL OF BIOTECHNOLOGY

A. GENERAL AND MOLECULAR GENETICS OF FILAMENTOUS MICROORGANISMS

Post 1. SERC Research Studentship
Post 2. Research Assistantship

B. MICROBIAL PHYSIOLOGY/ BIOCHEMISTRY

Post. 3 SERC Biotechnology Research Studentship for a project entitled "Beta-lactum biosynthesis in free and immobilized Streptomycetes.

Post 4. Research Assistantship — candidates should have an interest in analytical biochemistry and particularly HPLC techniques.

Posts 1, 2 and 3 are tenable for three years from 1st October 1985. Applicants should hold or expect to gain a first or upper second class honours degree in a relevant discipline. The successful candidates will be expected to register for a PhD Degree.

Post 4 is available immediately or as soon as possible and applicants should hold or expect to hold a degree in an appropriate subject and is tenable for a minimum of three years. For suitably qualified and motivated candidates there may be an opportunity to register for an M Phil degree.

Salaries for posts 1 and 3 will be according to SERC current regulations. Salaries for posts 2 and 4 will be according to University Research Assistant Scales since the project "Extended Use of Biocatalysts" is undertaken by PCL jointly with University of Kent at Canterbury and University College London under the auspices of the Institute for Biotechnological Studies. The programme is financially supported by the Department of Trade and Industry and seven major industries.

Please send a curriculum vitae and the names of two referees to the Personnel Officer, The Polytechnic of Central London, 309 Regent Street, London W1R 8AL, as soon as possible.

PCL is an equal opportunities employer. (6615)F

OXFORD UNIVERSITY

Research Laboratory for Archaeology

RESEARCH STUDENTSHIP (SERC)

for thermoluminescence, laser-based optical dating, radiocarbon dating using a tandem accelerator or archaeomagnetism using a SQUID cryogenic magnetometer. Suitable for physicist, chemist or earth scientist anticipating good honours degree.

Details: Dr M J Aitken, FRS. 6 Keble Road, Oxford OX1 3QJ, telephone (0865) 55211. (6659)F

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF NEUROLOGY

POSTGRADUATE RESEARCH STUDENTSHIP

Applications are invited for a research studentship tenable in the Muscular Dystrophy Group Research Laboratories, Newcastle General Hospital. The successful applicant will read for the degree of PhD. Two topics are available. (i) intermediary metabolism in skeletal muscle and the origin of metabolic myopathies; (ii) the use of cytochemical techniques to study the molecular differentiation of the muscle cell surface during development and regeneration of the neuromuscular junction.

Candidates should be qualified in an appropriate discipline (biochemistry, physiology, etc) and should possess or expect to obtain a First Class or Upper Second Class Honours degree.

Application should be made within two weeks of the appearance of this advertisement in the form of a curriculum vitae, and candidates should include the names of two academic referees. The project for which application is being made should also be identified. All correspondence should be sent to Professor J B Harris, Muscular Dystrophy Group Research Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne NE4 6BE, from whom further information may be obtained. (6643)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GEOGRAPHY

POSTGRADUATE STUDENTSHIP

Applications are invited for a postgraduate studentship to work with Dr Ann Henderson-Sellers on Synthesis of cloud climatologies.

This project builds on previous work in the department and is a contributory part of the International Satellite Cloud Climatology Project (ISCCP). The student will be expected to have, or aquire, a sound knowledge of meteorology. Much of the data analysis is computer-based so that previous experience of computer programming would be useful. The project is funded by a grant from the US Air Force and will involve the student collaborative work with US and European scientists. It is anticipated that applicants will hold, or hope to gain, at least an upper second class honours degreem in physics, mathematics or physical geography or a similar science subject.

Applications, together with the names of two referees should be received not later than 20 June, 1985, by The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote ref RV/291/N. (6620)F

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMISTRY

Applications are invited from Chemistry graduates, or those about to graduate for the following research studentships which will become available as from 1st October, 1985.

(1) A CASE studentship in conjunction with ICI Pharmaceuticals to study A Thermodynamically-Based Scale of Hydrogen Bond Basicities. (Dr M H Abraham).

(2) A CASE studentship in conjunction with the Imperial Cancer Research Fund to study Mechanisms of Aromatic Hydroxylations. (Dr J R Jones).

(3) A Ministry of Defence sponsored studentship to study Aromatic Amine Cure of Epoxy Resins. (Drs G J Buist and J R Jones).

(4) A CASE studentship in conjunction with ICI to study The Synthesis of Polysulphones from Arylsulphonic Acids and PCl_5. (Professor J B Rose).

Interested persons should send their curriculum vitae and the names and addresses of two referees to Dr J R Jones, Chemistry Department, University of Surrey, Guildford GU2 5XH, as soon as possible.(6647)F

GEORGE HENRY LEWES STUDENTSHIP

Applications are invited for this Studentship to pursue original investigations in Physiology. Appointment may be from 1 October 1985 for one year with a possibility of renewal for up to two further years. The award will provide an annual maintenance grant in line with the maintenance element of a Research Council research studentship; and the trustees will pay University and College fees for the holder at the rates charged to science research students from the UK.

Candidates should by 28 June 1985 send (a) a statement of their qualifications and their need for pecuniary help, (b) the subject of their proposed research, and (c) the names and addresses of two referees, to Professor R D Keynes, Physiological Laboratory, Downing Street, Cambridge CB2 3EG, from whom further particulars may be obtained. (6639)F

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF MICROBIOLOGY

RESEARCH STUDENTSHIP IN MOLECULAR BIOLOGY

Applications are invited from persons possessing or expecting to obtain at least an Upper Second Class Honours degree in a Biological Science.

The successful applicant will join a group involved in the study of microbial pathogenesis using molecular genetic techniques.

Further details may be obtained by contacting Dr I N Clarke on Southampton 0703 777222 ext 3853. Please quote reference number AJS/85/37/N. (6671)F

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

SERC RESEARCH STUDENTSHIP

Photosensitization of Tumours

Applications are invited for the above studentship, tenable from October 1985, to study fundamental biochemical aspects of photochemotherapy, a new approach to cancer treatment, involving photosensitization of tumours by porphyrin-containing drugs.

Candidates should have, or expect to obtain, a good Honours degree in Biochemistry or an appropriate related discipline.

Further information may be obtained from Dr S B Brown, Department of Biochemistry, University of Leeds, LS2 9JT (0532 431751 ext 7500), to whom applications (including the names of two referees) should be sent. (6663)F

UNIVERSITY OF SHEFFIELD

DEPARTMENTS OF BIOCHEMISTRY AND MICROBIOLOGY

SERC EARMARKED STUDENTSHIP FOR PROTEIN ENGINEERING

A studentship is available for three years from October 1985 to work for a PhD on in vitro mutagenesis of a bacterial glutamate dehydrogenase. The student would join an interdisciplinary team headed by Professor J R Guest (DNA manipulation), Dr P C Engel (enzymology) and Dr D W Rice (crystallography) but would primarily be involved in the DNA aspects of the project.

Applicants should have or expect to obtain a First or Upper, Second Class Honours Degree in Biochemistry or Microbiology.

Applicants naming two referees should be sent to Dr P C Engel, Department of Biochemistry, University of Sheffield, Western Bank, Sheffield S10 2TN by 14 June 1985. Quote ref: R247/G. (6616)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ZOOLOGY AND COMPARATIVE ANATOMY

SERC CASE STUDENTSHIP

Applications are invited for a SERC CASE Studentship to work in collaboration with Dr F Y Liew (Wellcome Research Laboratories, Beckenham) on the protection potential of T cell responses in mice to genetically engineered specific HSV glycoprotein peptide fragments.

Applicants should have at least 2.1 Honours degree in Biochemistry, Biology, Immunology or Genetics.

Applications, together with the names of 2 referees should be made by 30 June 1985 to Dr W L Chan, Dept of Zoology and Comparative Anatomy, University College London, Gower Street, London WC1E 6BT. Tel: (01) 387 7050 ext 428. (6675)F

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY

SERC STUDENTSHIP

Applications are invited for a 3 year studentship to work on the structure of squid rhodopsin and its role in activation of the photoreceptor enzyme cascade, using electron microscope image analysis and biochemical methods. Applicants should have, or expect to obtain, a good Honours degree in Biophysics, Biochemistry or related subjects.

Applications with a curriculum vitae and names of 2 referees should be sent as soon as possible to Dr H R Saibil, Department of Zoology, South Parks Road, Oxford OX1 3PS, to whom further enquiries may be made (Tel (0865) 56789 ext 317). (6657)F

UNIVERSITY OF READING

SUB DEPARTMENT OF HORTICULTURE

SERC CASE STUDENTSHIP IN PLANT PHYSIOLOGY

Applicants are invited for a CASE studentship tenable from 1 October 1985 to study genetic and environmental effects on the physiology and biochemistry of pod development in cocoa, in collaboration with Cadbury Schweppes plc.

Candidates should possess, or expect to obtain, a first or upper second class honours degree in Plant Sciences, Biochemistry or a closely related subject.

Further details may be obtained from Dr P Hadley, Sub Department of Horticulture, University of Reading, Earley Gate, Reading RG6 2AU. Applicants should send a curriculum vitae with the names of two referees not later than 10 June 1985. (6618)F

IMPERIAL COLLEGE (University of London)

CENTRE FOR BIOTECHNOLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited from candidates, preferably with a background in molecular biology, who hold, or expect to be awarded, at least two: one honours in biochemistry or biology for SERC research studentship. The award is for three years commencing October 1985. The project will involve the supression of gene expression in plants by anti-message RNA.

Informal inquiries may be made to Doctor Conrad Lichtenstein, Tel: (01) 589 5111 Ext 4112/7094.

Applications (cv and two academic referees) should be sent to me no later than June 30th 1985.

To: Centre for Biotechnology, Imperial College, London SW7 2AZ. (6690)F

UNIVERSITY OF ABERDEEN

DEPARTMENTS OF CHEMICAL PATHOLOGY AND THERAPEUTICS AND CLINICAL PHARMACOLOGY

POSTGRADUATE STUDENTSHIP

Applications are invited from graduates to work on a research project involving the use of isolated renal proximal tubular cells to investigate mechanisms of drug-induced nephrotoxicity. Candidates should have a good Honours degree in Biochemistry, Pharmacology or a related subject.

The studentship is initially for one year and the student will be registered for an MSc. Applicants, with a full curriculum vitae and the names of two academic referees, should be sent to Dr P Whiting, Department of Chemical Pathology, University Medical Buildings, Foresthill, Aberdeen AB9 2ZD as soon as possible. Further details are avalable from Dr Whiting (telephone 0224-681818, ext 2822) or Dr G Hawksworth (ext 2463). (6685)F

UNIVERSITY OF WARWICK

DEPARTMENT OF CHEMISTRY

SERC CASE AWARD

Solution Chemistry of Technetium : Redox and Extraction Properties

Applications are invited from graduates or those expecting to graduate this Summer with at least a class II-I honours degree in chemistry, for this studentship. The project, carried out in collaboration with British Nuclear Fuels plc, will be concerned with kinetics of chain reaction of TcO_4^- with hydrazine and with the co-extraction of Tc with UO_2^{2+} ion. Normal SERC rates will be supplemented by £600 pa.

Further details may be obtained on application to the Personnel Office, University of Warwick, Coventry CV4 7AL. Please quote Ref No 42/A/85/O. Closing date for applications 21st June 1985. (6672)F

UNIVERSITY OF GLASGOW

BIOTECHNOLOGY UNIT

SERC CASE STUDENTSHIP — ICI

To clone and study expression of resistance and production genes from Streptomyces for an antibiotic of interest to ICI. The project is supervised jointly by Dr I S Hunter (Glasgow) and Dr P Groves (ICI, Corporate Lab, Runcorn).

Applicants should have, or expect to obtain, a first or upper second class honours degree in a related biological science. Interviews will be conducted towards the end of June.

Applications (CV and names of two referees) should be sent to Dr I S Hunter, Institute of Genetics, Church Street, Glasgow G11 5JS, before June 13th, 1985. (6596)P

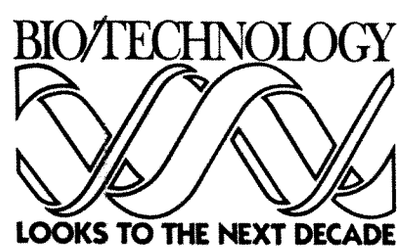
AWARDS

ROSENSTIEL AWARD IN OCEANOGRAPHIC SCIENCE

Nominations are invited for the 1985 Rosenstiel Award in Oceanographic Science.

This award, administered on behalf of the Rosenstiel Foundation by the Rosenstiel School of Marine and Atmospheric (RSMAS) at the University of Miami recognizes outstanding contributions to marine science, including oceanographically relevant aspects of atmospheric science, and fundamental developments in ocean engineering. The award consists of a cash prize, currently $5,000, and a medal. The recipient of the award will be invited to spend a week at RSMAS for discussions with faculty and students. The award will be presented at that time.

To accumulate the multidisciplinary value of oceanographic science, the award recognizes, on a rotating basis, achievements in four broad disciplinary areas. In 1985 the emphasized discipline will be physical oceanography and air-sea interaction. The achievements recognized may consist of contributions towards the development of ocean science in general, or of more focussed individual research of recognized impact on our understanding of the marine environment.



Nominations for the 1985 award for outstanding achievement in physical oceanography or air-sea interaction should be directed to Dean Alan Berman, Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149-1098, before August 15, 1985. Nominations should include a brief justification together with relevant reference. The selection panel would especially welcome nominations of outstanding younger scientists, whose early contributions suggest a continuing role of leadership in the field. (NW1796)N

CONFERENCES and COURSES

ATTENTION SCIENTISTS AND RESEARCHERS

Posters are now being accepted for BIO/TECHNOLOGY's premier conference

BIO/TECHNOLOGY

LOOKS TO THE NEXT DECADE

January 20-22, 1986, Clarion Hotel, New Orleans

You are invited to submit abstracts of work with commercial implications to:

Research Editor
BIO/TECHNOLOGY Conference
65 Bleecker Street, New York, NY 10012

Ideas suitable for support from corporate or venture funding are particularly welcome.

Conference Themes:
Day 1: The Molecular Biology of Plants & Animals
Day 2: Commercial Production Processes
Day 3: Innovations in Pharmaceuticals & Immunology

ASSOCIATESHIPS

Research Associateship in Experimental Nuclear Physics

There is a vacancy for an experimental physicist to join the nuclear physics group as a Research Associate at the Daresbury Laboratory, an establishment of the Science and Engineering Research Council situated in the north Cheshire countryside.

The group is involved in a research programme on the Nuclear Structure Facility, a large tandem accelerator which currently is operating at up to 20 MV on terminal.

Currently, the principle areas of study are: direct reactions with light and heavy ions, production of exotic nuclei far from stability, nuclei with very high angular momentum, nuclear breakup and fragmentation and studies of isotope shifts and hyperfine structure using laser-induced resonance fluorescence. Experimental equipment includes a Q3D magnetic spectrometer, advanced gamma-ray and neutron detection apparatus, and a 1m diameter scattering chamber. An isotope separator with an associated dilution refrigerator and a beam line for laser studies has recently been brought into full operation, a recoil separator is in an advanced commissioning stage, and a heavy-ion polarised source is under construction.

Applicants (male/female) should possess a PhD degree or expect to obtain one during 1985.

An appointment will be made at a salary between £9,977 and £11,220 per annum depending on age, ability and experience. The post is available for a fixed term of three years and is superannuable.

CLOSING DATE: Sunday 30th June, 1985.

For further information please write or telephone: Dr. J. Lilley on Warrington (0925) 65000 Ext. 558.

Application forms may be obtained from and should be returned quoting reference DL/912 to: The Personnel Officer, Science & Engineering Research Council, Daresbury Laboratory, Daresbury, Warrington, Cheshire, WA4 4AD. (6623)O

ASSISTANTSHIPS

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
COURTAULD INSTITUTE OF BIOCHEMSITRY
A POST DOCTORAL RESEARCH ASSISTANTSHIP IN MOLECULAR BIOLOGY

financed by The Cancer Research Campaign is available for work in a Molecular Toxicology group examining the role of glutathione and glutathione transferases in carcinogenesis, the cancer cell and cancer chemotherapy. The successful applicant would join several other molecular biologists from this group who work in association with Professor Roger Craig's Medical Molecular Biology Unit. The post is tenable for three years and the salary will be on the 1A scale according to age and experience.

Applications, in writing with curriculum vitae together with the names of two referees should be sent to: Professor Brian Ketterer, Cancer Research Campaign Molecular Toxicology Group, Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London W1P 7PN. (6621)P

THE SCHOOL OF PHARMACY
University of London
DEPARTMENT OF PHARMACEUTICAL CHEMISTRY
POSTGRADUATE AND POSTDOCTORAL RESEARCH ASSISTANTSHIPS
in Chemical and Biological NMR Spectroscopy

Candidates should have shown scholarly achievement in chemistry, biochemistry, biophysics or pharmaceutical chemistry. Research in the department includes synthetic and medicinal chemistry, peptide and protein chemistry, recombinant DNA, receptor structure and function, enzyme structure and function, metabolism, surface and colloid chemistry, electroanalytical chemistry, mass spectroscopy, NMR spectroscopy, light scattering and diffusion.

Emphasis is placed upon applications of chemistry and biochemistry to the pharmaceutical sciences.

Salaries offered (Research Assistants) range from £6,600 — £12,150 pa plus £1,233 pa London Allowance.

Applications, which should include the names of two referees and two copies of CV should be sent to Personnel Officer, The School of Pharmacy 29/39 Brunswick Square, London WC1N 1AX. (6673)P

DURHAM UNIVERSITY
DEPARTMENT OF PHYSICS
Applications are invited for a SERC funded
POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

Tenable for 3 years from 1 October 1985 for work in Observational Cosmology using machine measured photographic data, spectroscopic and CCD photometric data for large samples of galaxies and QSOs.

Initial salary £7,520 — £8,920 per annum on Range 1A plus superannuation.

Applications (3 copies), naming three referees should be sent by 24 June 1985 to the Registrar, Science Laboratories, Durham DH1 3LE, from whom further particulars may be obtained. (6644)P

SEMINARS and SYMPOSIA

FIRST INTERNATIONAL SYMPOSIUM ON CELLULAR ENDOCRINOLOGY

"From Embryos to Cells: Hormonal Control of Differentiation," **12 to 16 August 1985, Lake Placid, New York.** Sponsopred by the W. Alton Jones Cell Science Center, Inc. Symposium co-chairmen: Drs. Gorden H. Sato, Ginette Serrero, and Jun Hayashi. Symposium will include lectures and afternoon poster sessions. **For further information and registration forms, please call: Carla Cheyne, Symposium Secretary, telephone: 518-523 1252** (NW1789)M

ACCOMMODATION

PROFESSOR OF Pharmacology at Catholic University Rome in London for Academic Year Sept 1985 to July 1986. Will be working with Prof Gvr Born, FRS, King's College, Strand & with Prof A Maseri, Royal Postgrad Med Sch, Hammersmith Hospital. Seeking accommodation for himself, wife & 1 child for above period. Requirement 2/3 bedroom flat/small house to rent up to £140 p/wk. Please reply urgently Gvr Born, Pharmacology, King's College, Strand, London WC2R 2LS. (6655)S

APPOINTMENTS WANTED

advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of $8 per line. (Personal Box Numbers $10.00). Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 65 Bleecker Street, New York, NY 10012. (890)B

BIOSYSTEMS UPDATE

Introducing the high performance, low cost, fully automated DNA Synthesizer.

The new Model 381A DNA Synthesizer optimizes the efficient phosphoramidite chemistry to reliably and economically produce high quality oligonucleotides.

Automatic rinsing and priming of reagent lines when new chemicals are added, menu-driven software and stable, prepackaged reagents make the 381A easy to use.

Results *and* Affordability

The new Model 381A produces high purity, defined-sequence oligonucleotides quickly and economically. It delivers routine coupling yields of 98–100% and the capability to synthesize oligonucleotides with more than 100 bases.

The 381A is a *complete* instrument-reagent system with the proven chemistry and precision design that have made Applied Biosystems the world leader in synthesis technology. Affordably priced, the 381A brings every researcher the speed and reproducibility of automated DNA synthesis with the convenience of an in-lab instrument.

Advanced Capabilities

The 381A can produce 50 to 100-mers providing greater flexibility in gene synthesis strategy by minimizing the number of purifications and ligations. With the efficient phosphoramidite chemistry, probes and primers can often be used without purification. Specific primers for Sanger dideoxy sequencing can be ready for use in less than 18 hours.

Production of mixed probes can be accomplished without any premixing of bases, and the addition of unusual bases can be completely automated. Small amounts of probes and primers or up to 10 mg of DNA for physical studies can be made economically and automatically with no hardware modifications.

Fully Programmable

The 381A can be operated with the standard synthesis cycle or used to develop and store new chemistry methodologies incorporating existing or user-defined functions. Users can optimize cycles for up to five different nucleotides or derivatives. Integral battery with automatic re-start preserves synthesis parameters and user-designed cycles when power is interrupted.

Immediate Delivery

Compare and you'll agree: The 381A is a remarkable performance/price value. Your local Applied Biosystems representative has all the information for immediate purchase and shipment. Contact us at one of the offices listed below or key reader service number **08**.

Hybond™ the choice in blotting membranes

Hybond™ membranes are the ideal transfer membranes for nucleic acid and protein blotting, offering:

- **Flexibility** – choose nylon or nitrocellulose
- **Convenience** – a wide variety of shapes and sizes
- **Optimum performance** – supported by comprehensive protocols
- **Compatibility** – rigorous applications testing ensures compatibility with our extensive range of blotting products

As you would expect from Amersham,
Hybond membranes are subjected to our usual quality assurance programmes.

Hybond-N Nylon
Hybond-C Nitrocellulose

For further details please contact our Research Products Technical Service department or your local representative.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product – not your experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

GUIDE TO AUTHORS

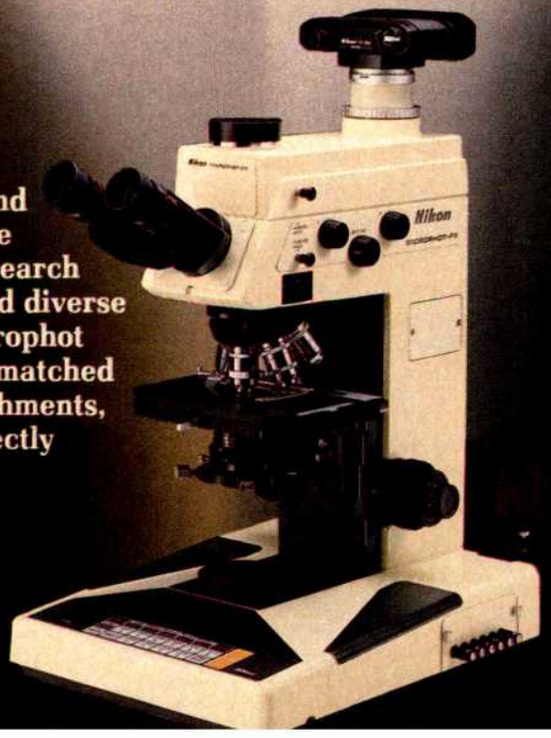
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

NIPPON KOGAKU K.K.
Fuji Bldg., 2-3, Marunouchi 3-chome,

You Work With Many Cell Types. So Does Opti-MEM™ I.

Introducing the First Multi-use Reduced Serum Medium.

Only Opti-MEM™ I supports optimal growth with reduced fetal bovine serum for a wide variety of mammalian cells. Most cells routinely cultured in serum-supplemented medium may be directly transferred into Opti-MEM™ I with a minimum of 50% reduction in serum. In addition to its versatility, many other unique features make Opti-MEM™ I the optimal choice for most cell culture needs.

High performance. Opti-MEM™ I actually *outperforms ordinary serum-supplemented media* in many applications.

Stringent testing. Opti-MEM™ I is performance-tested for cloning efficiency and growth promotion using various mammalian cell types, including murine myelomas, hybridomas and adherent cultures. In addition, Opti-MEM™ I is tested for pH, osmolality, endotoxin level and bacterial/fungal sterility.

Stability. Opti-MEM™ I has a shelf life of six months from date of manufacture.

Ease of preparation. Opti-MEM™ I is ready for use in only three steps: add 2-mercaptoethanol (included); mix thoroughly; and add fetal bovine serum.

Economy. Opti-MEM™ I not only decreases the amount of costly serum needed, it also is less expensive than most other reduced serum media.

For more information about Opti-MEM™ I, including performance data for a variety of cells, ask for our free technical brochure.

GIBCO Opti-MEM™ I, the reduced serum medium that works the way you do.

Opti-MEM™ I was developed by Hybridoma Sciences, Inc., Atlanta, Georgia.
For *in vitro* diagnostic use.

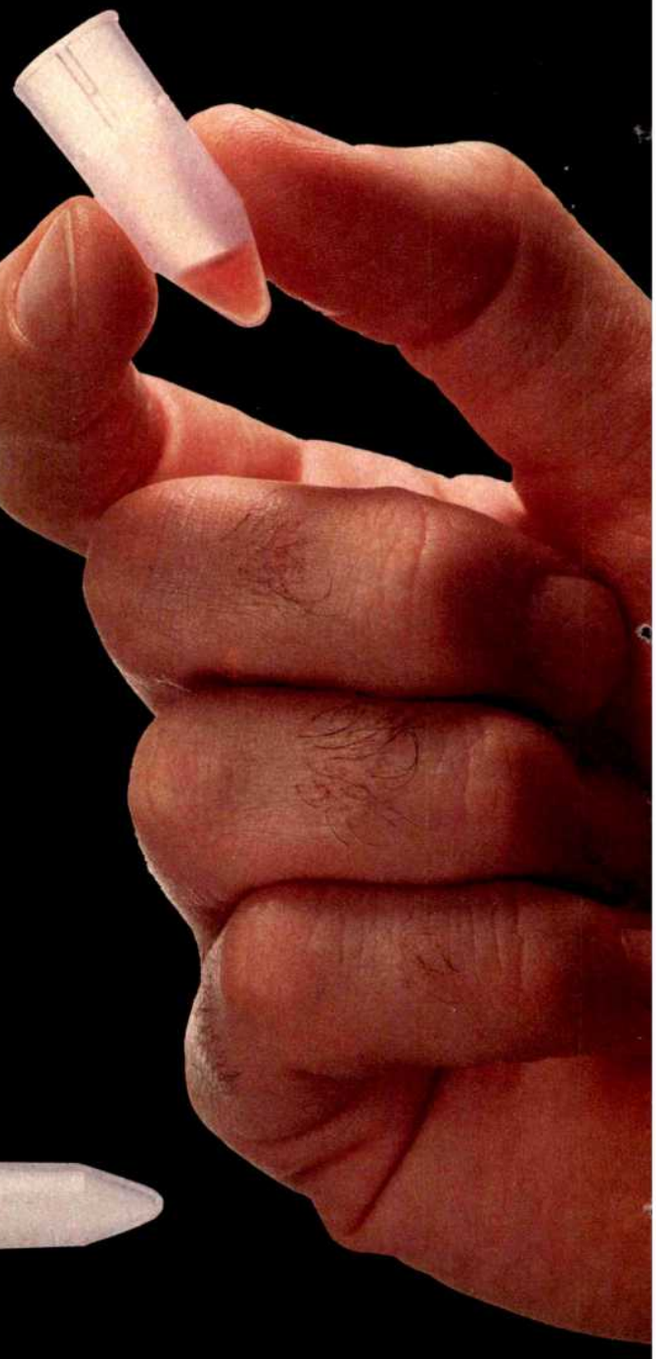
Microconcentration made easy.

Centricon™

Are you concentrating or desalting samples containing plasmid DNA, restriction fragments, viruses, bacteria, proteins, or enzymes?

Are you purifying microvolumes of biological fluids, cell culture media, or fermentation broths?



Now you can do it easier than ever before—with high recovery and low biological loss—using the Centricon Disposable Microconcentrator. There's nothing else like it.

Centricon yields 25–50μl concentrate from a 2ml sample by only a 30 to 60 minute spin in a fixed-angle centrifuge. That's all you need: no special equipment, no awkward procedures, no apparatus to clean up. Centricon is fast, simple, efficient.

Call the Toll-Free Hotline:
800-343-1397 Talk directly to our technical specialist about your application. Ask about our Applications Monographs, our Applications Source File, and our Microseparation Catalog. (In Massachusetts or internationally: 617-777-3622.)

the question is...

how to select a fermentation system

which is universal, normalized, versatile and suitable for large-scale as well as pilot-scale production of bacterial-, cultivations and mass cell propagation

the answer is...

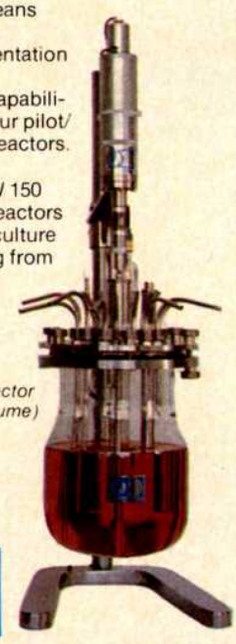
contact-flow

About Contact-Flow

Contact Flow bv , with its main office located in Ridderkerk, The Netherlands, is one of the leading manufacturers of fermentation equipment. The equipment, is characterized not only by the universal possibilities of application and standardizations, which have been carried through consequently, but as much by mutual interchangeability of the parts and the particularly solid construction, which guarantees a long length of life. Moreover the product range comprises an extended series of satellite equipment as to optimalize efficient application in practice. The equipment of Contact Flow bv has been put into practice all over the world. We can give you detailed information about the Contact-Flow products and also about our extensive programme of biochemical satellite equipment and complete fitting-up of laboratories and custom made fermentation equipment.

Introducing two of latest products

① The Fermentrol



Integrated Fermentation Process Control

The Fermentrol provides computerized measurement and control for all fermentation processes, especially those involving **mass propagation of mammalian cells**.

② The Bench Top Bioreactors

The NW 100/NW 150 Bench Top Bioreactors were developed to provide a cost effective means of conducting controlled fermentation studies without sacrificing the capabilities offered on our pilot/ production Bioreactors.

The NW 100/NW 150 Bench Top Bioreactors are available in culture volumes running from 0,5 up to 10 litre in glass and stainless steel.

Reader Service No.79

nature

NATURE VOL 315 6 JUNE 1985

What will Eureka discover?

West European governments are warming to the French proposal for a combined venture in high technology. The motives are political, but the risks are high.

THE President of France, M. François Mitterrand, must by now be thoroughly exasperated by his European counterparts. Throughout the five years of his presidency, M. Mitterrand has been preaching the need for European collaboration in high technology. Every summit meeting of the heads of the industrialized nations has been treated to a homily on the subject, and has been met with a blend of incomprehension and scepticism. Almost as if to humour the French government, the others agreed four years ago to mount several attempts at coordination in specific fields, providing a frisson of panic for officials in advance of succeeding summit meetings, but which have not yet produced much of substance. So why should M. Mitterrand have expected more from this year's summit, at Bonn? Indeed, because the proposed collaborative programme, called Eureka, had been advertised in advance as an alternative to collaboration by West European governments in the US programme of research on ballistic missile defences, otherwise known as the Strategic Defense Initiative (SDI) or "star wars", he had every reason to expect another rebuff. That, indeed, is what happened at Bonn, but since then there has emerged a fondness for the brave concept of Eureka that is only partly diminished by the general ignorance of what Eureka is supposed to be, how it is to be organized and what it may accomplish. For the time being, the working principle seems to be that a good idea should not be crabbed simply because it is vague. More generously to all concerned, even professionally pragmatic governments such as the British now seem to be willing to consider what Eureka might have to offer (which has surprised the French).

Eureka

For fear that Eureka may get out of hand, it is important to be clear that government's motives are at best mixed. The idea of foreign collaboration in the SDI research programme seems to have cropped up first during the British prime minister's visit to Washington last December, and to have been a British suggestion whose implications were not fully appreciated at the time. Now, the US government seems to value collaboration for political reasons: governments that agree to collaborate on the research are likely to be stauncher allies in resisting the Soviet argument that even the research programme is an abomination (which it is not). Governments (Britain and West Germany, for example) at first attracted to collaboration saw two advantages: the opportunity to learn some high technology at no direct cost and the opportunity to influence the political decision that may eventually have to be made about deployment. They have since been given pause by the more careful calculation that legal difficulties would restrict the technical benefits they might hope to win and that junior partners in such a gigantic enterprise might in the end have very little influence. The French government, traditionally suspicious of US influence in Western Europe, is consistent in its unwillingness to collaborate. Politically, the interested governments should set their faces firmly against collaboration in SDI unless they can win terms that will assure their independence in the strategic arguments that must lie ahead. The more immediate question is whether Eureka is in any way the alternative it purports to be.

Eureka, essentially a French conception, is to some extent an exercise in continental (European) chauvinism. It is firmly in the tradition of previous French technological initiatives leading to the Concorde (an uneconomic supersonic passenger aircraft), the European Airbus (a range of successful commercial aircraft), the Ariane satellite launcher (probably a success) and Superphénix (a prototype fast reactor, still unproven). Although many of these and other projects have been (or have seemed) worthwhile in themselves, French enthusiasm for them has in part derived from the wish to narrow what used to be called the technology gap between the United States and Europe (not to mention France). It is also worth remembering that some projects with this objective, such as the plan in the 1970s to beat off the US computer invasion of France, have been costly failures.

Solutions

Successful or otherwise, however, these projects have in common the circumstance that, from the point of view of Western Europe as a whole, they are second-bests. If the European Communities were not functioning as an efficient common market, and in the process generating the wealth of which Europe is potentially capable of generating, the need for the artificial definition of projects that will increase industrial company spending on research and development would have long since faded away. Instead, European companies would be spending from their own resources on research and development on a scale commensurate with that of their rivals in the United States and Japan — and the pace of innovation would presumably be enhanced commensurately. Throwing public money at joint projects must therefore be counted a stop-gap expedient for encouraging industrial development in Europe. Governments will have to worry less when there is a common market, but this will come about only when the same governments abandon their restraints on European competition, especially their failure to follow the principle that public purchases of goods and services should be open to competition. And for the time being, even (or especially) in France, national chauvinism takes precedence over European chauvinism.

Throwing money at Eureka, at least while the project is as ill-defined as at present, could be worse than a mere waste of money. As so far described, the essential chacteristics of Eureka are that it should be a big project and that it should include the principal components of the SDI programme — information processing, high-powered lasers, particle beam technology, artifical intelligence and so on. For the time being, Eureka is a rag-bag of technology looking for a goal. No doubt more tangible objectives will emerge in the next few weeks. But as there is no reason to expect these to be related to market needs of any kind, the obvious risk is that Eureka will be a recipe for diverting

Biological manuscripts

Miranda Robertson, Biological Sciences Editor of *Nature*, is now based in the Washington office of *Nature*. Manuscripts offered for publication may be sent, as at present, to either the London or the Washington office; with the benefit of good communications, the speed with which manuscripts are dealt will be independent of the place at which they are received. But authors are asked please in future to send **four copies of manuscripts** intended for publication (one for each office and two for referees).

European research efforts from the more realistic goals that European companies have already set for themselves. Nobody will deny that in the course of such a programme of technological development, European technology would acquire new skills. European politicians are fond of insisting that "science for its own sake" is a waste of resources, which is debatable; what they forget is that technology, however marvellous, which is not harnessed to practical objectives has literally no purpose.

The lessons for the West European governments lately attracted by Eureka are therefore plain. Their first objective should be to sweep away the restraints on movement and competition which at present make European technology less effective than it might be. Second, they should be prepared to back with public money only those projects emerging from the discussion of Eureka that seem likely to be commercially successful as well as technically challenging. Third, they should persuade each other that technological chauvinism is not a game worth playing for its own sake, but that it may even divert scarce skill for more useful tasks. Finally, they should acknowledge among themselves (and tell their voters as much) that the technology gap, although not necessarily here to stay, cannot by its nature be quickly bridged. Impatience is a dangerous trap. □

Fraud prevention

Only colleagues can judge the value and authenticity of a person's work.

THERE is much in the belief that the pressure on people to publish research articles is part of the explanation for the cases of fraud in science that have become notorious in the past few years, but too much attention should not be paid to the suggestions from Los Angeles last week (page 447) that journals could do much to help by, for example, stamping out the tendency towards the multiple publication of the same data. Quite apart from the practical difficulties (identical manuscripts simultaneously submitted, for example), better regulation at this stage of the publication process amounts merely to the remedy of symptoms, not the underlying disease. In any case, if repeated publication helps the process of communication, by what test is that by itself a crime? Far better that reforms should aim at the abatement of the pressure to publish.

How does the pressure arise? Now that young people's promotion prospects in academic life are substantially determined by their record in research, it is natural to look for fraudsters among the rising stars. And this has partly been confirmed. But why, then, have the most conspicuous cases of fraud apparently arisen at some of the most distinguished laboratories? Perhaps work done in relative obscurity is scrutinized less carefully, while it is also possible that the pressure to seem to succeed is all the greater the more success there is about. But a further disturbing possibility suggested by last week's discussion in Los Angeles is that there may be a symbiotic relationship between those who advance their reputations by fraud and much more senior people whose reputations are apparently established. For however replete a person's resume may be with research papers, his present influence may depend to a large extent on being thought still active in research. Indeed, the success of a department or a whole school in winning research funds from outside may depend on its head's reputation as one who still beavers away in the laboratory.

In the circumstances, it is no great surprise that great men have been vulnerable to younger fraudsters. Sadly, these relationships are often indistinguishable from those between truly great men and younger talented protégés. The remedy is not easily found, for one of its components would have to be a mutual recognition by the scientific community and those among its leaders who have become inactive that it is still possible for an established scientist to run a creative laboratory even when his direct contribution to the work is small. Then, only close colleagues would be in a position to distinguish wheat from chaff — which, in any case, is the present state of affairs. □

Educational yardsticks

The British government should not attempt to measure institutional efficiency.

THE British government's empty discussion paper on the future of British higher education (see *Nature* 23 May, p.270) has predictably been condemned by academics and the organizations which represent them, but it is unusual that the chairman of the Committee of Vice-Chancellors and Principals, Dr Maurice Shock, should have so openly broken with the conventions of polite restraint. For academics and even the author of the discussion document, the Secretary of State for Education and Science, however, the most significant development in the past two weeks may be the volume of protest there has been from the House of Commons at the emptiness of the policy now made public.

A large part of the trouble of the universities in particular during the past five years has come about because they had allowed themselves to lose their political friends, once equally strong on both sides of the political spectrum. If the opposition parties now do no more than recognize that the management of higher education in Britain has become a stick with which to beat the government, higher education cannot be confident of benefiting.

But there is always a chance that the politicians will once again come to recognize the social importance of higher education, which is the only long-term guarantor of well-being.

Calculations

Meanwhile, universities and others would do well to watch out for a little-noticed appendix of the discussion document, which purports to be a first tentative attempt to calculate "performance indicators" for the objective measurement of efficiency in higher education. The idea is that there should be constructed a set of numbers measuring such characteristics of higher education as the cost of educating people in different kinds of institutions, or by means of a course of instruction, and culminating in an attempt to quantify the social value of graduates in different fields.

To be fair, the government's document emphasizes that the numbers tucked away in last month's appendix must be taken with several pinches of salt — but it then goes on to promise (or threaten) better numbers in the future. The snag, on the present showing, is that the fact that the numbers now published would not satisfy the requirements of examiners of beginning-economics courses is unlikely to diminish the influence they will have on public policy.

The most obvious defect of the calculations now attempted is that the average costs which are their chief product may be entirely misleading. It is not surprising that the average cost of educating students in British universities turns out to be higher, subject by subject, than in polytechnics, or that a medical degree is more expensive than one in engineering (which nevertheless is shown to be surprisingly higher than a science degree). But these numbers are irrelevant to the economic management of a system of higher education already in being, when the practical questions should be whether this or that change in the pattern of an institution's work would yield this or that benefit, and where the useful answers will be provided in terms of marginal, not average, costs.

All this has long since been recognized. In the present condition of British higher education, the first implication of a properly conducted study would probably be that there is too much educational plant which is under-used, or that the government could at this juncture buy a great deal of higher education cheaply, if it chose to follow that enlightened course.

Because there is every likelihood that the British government will persist with its economic analysis, and that the results will be used for a further shaping of the system as a whole, academics (and economists in particular) should do what they can to see that the job is done properly and independently. □

Nuclear testing

Size of Soviet tests disputed by geophysicists

Los Angeles

US geophysicists made angry accusations last week that the US government is "lying" over estimated yields of Soviet underground nuclear tests. Allan Lindh of the US Geological Survey said at a symposium on treaty verification organized by the American Association for the Advancement of Science (AAAS) that geophysicists agree there is no evidence that the Soviet Union has cheated on the Yield Threshold Test Ban Treaty (YTTBT), which places an upper limit of 150 kilotons on weapons tests. The Department of Defense (DoD) was accused of hiding the evidence from citizens behind a "veil of secrecy".

The treaty verification symposium was one of the more heated sessions at this year's AAAS meeting, which included discussions on several aspects of arms control. Sally Horn of DoD repeated President Reagan's charge that the Soviet Union has probably exceeded the 150-kiloton limit in the YTTBT, which went into effect in 1976. Other speakers, notably Colin Gray of the National Institute of Public Policy, argued that because the Soviets have cheated on "most if not all" arms treaties (except the Nuclear Non-proliferation Treaty), such treaties have been "harmful or irrelevant".

Although much of the information needed to judge Soviet compliance with arms treaties is subject to security classification, analyses of seismic records are published in the open literature, and have been the subject of long-running arguments. The dispute centres on the method used to estimate explosive yields from seismic data, and in particular the bias parameter incorporated to take account of the local geology of the Soviet test site at Semipalatinsk.

Yield estimates are derived from body P-waves at a frequency of about 1 Hz. The relationship between the magnitude of an event judged from P-wave amplitude and explosive yield has been thoroughly investigated at the Nevada Test Site in the southwestern United States. According to Jack Evernden of the US Geological Survey, confirmed data published more than 10 years ago (based on comparisons with other types of seismic waves) indicate that for the Semipalantinsk test site a value of 0.4 should be subtracted from magnitudes to estimate explosive yield. That judgement has recently been confirmed by, among others, the Air Force Technical Applications Center in Florida, which has a primary responsibility for yield estimates. Present US government estimates, however, use a bias value of only 0.2, resulting in yield estimates that are twice as high, as with the 0.4 value. Evernden says the decision to use a bias of 0.2 was "obscure", and claims there is unanimity among geophysicists that the higher value is correct. When the higher value is used, yield estimates converge on the 150-kiloton legal limit.

The DoD representative at the symposium was unable to shed any light on the matter. She professed unfamiliarity with the detailed arguments but admitted there was a "debate" on the question.

Seismic verification would be a crucial factor in any comprehensive test ban that might be negotiated in future; negotiations for such a ban were suspended in 1980. Evernden, who used to work for DoD, publicly rebutted a paper published in *Science* in January this year by Willard Hannon of Lawrence Livermore Laboratory, which questioned whether a politically plausible detection network could detect most low-yield explosions. In Evernden's view, almost all test explosions above 1 kiloton (the limit of military value) can now be distinguished from earthquakes by a simple network of non-array detection stations. Others at the conference argued, however, that the lack of progress towards a more comprehensive test ban resulted from a lack of political will rather than for technical reasons. **Tim Beardsley**

US research restrictions

Pentagon prefers export control

Los Angeles

THE US Department of Defense (DoD) has told the research community that it will in future make routine use of export regulations to restrict access of foreign nationals to scientific data which, while not classified, might be of military significance. As a result, many scientific and technical conference organizers will be obliged to put sensitive material in special "export-controlled sessions" restricted to US nationals and to foreign nationals only if validated by their embassies. Participants in such sessions must undertake to keep the restricted material confidential.

The new policy was spelled out at a meeting of the American Association for the Advancement of Science by Dr Sumner Benson, substituting for Richard Perle, Assistant Secretary for Defense for international security policy. In the past, some technical societies have voluntarily restricted access to conferences for fear of violating arms traffic regulations: the new policy, by giving control to DoD, will make such voluntary censorship unnecessary.

Export controls will be used only for scientific data that are not considered "fundamental". According to a DoD policy instituted last year by Richard DeLauer, then Under-Secretary of Defense for research and engineering, "fundamental" research on university campuses is controlled only by use of security classification.

The new policy outlined by Benson would implement authority in the 1984 DoD Authorization Act allowing DoD to restrict unclassified data with military or space applications. That authority was granted because of concern that the Freedom of Information Act might allow the Soviet Union access to sensitive research results, because data released under the Freedom of Information Act cannot be controlled by export regulations.

Benson's announcement clears up much of the confusion that has been rife since DoD enacted export-controlled sessions at an April meeting of the Society of Photo-Optical Instrumentation Engineers in Virginia. Then, it was unclear whether such sessions would become commonplace, but at at a recent private meeting, organized by the Institute of Electrical and Electronic Engineers DoD apparently declared itself happy with the formula. It remains to be seen whether learned societies will be happy to accept export-controlled sessions as a matter of course.

The new policy is a further development in the administration's continuing efforts to restrict access to sensitive technology. Benson said that reliance on security classification would be expensive and cumbersome but that export-controlled sessions would be more predictable and flexible, while allowing maximum access to restricted information consistent with national security. Benson said that the new arrangements would also have the advantage of not penalizing researchers at institutions which have set their faces against classified research on-campus.

The export regulations to which DoD is appealing are themselves being revised. According to the latest draft, information resulting from research contracts which embody restraints on free publication — even non-military contracts — would require a validated export licence to be transmitted to foreign nationals.

Boyd McKelvain of General Electric Co. made a strong plea at last week's meeting for moderation in the use of export regulations. McKelvain said he was unaware of any cost/benefit analysis supporting further restriction of data flowing to friendly nations, and warned that industrial laboratory managers are concluding that they will be forced to avoid employing foreign nationals. In McKelvain's view, unilateral action by the United States to prevent access by foreign nationals to US research could backfire and lead to reprisals, causing economic damage to US industry. **Tim Beardsley**

European defence programme

Favourable noises for Eureka

EUREKA, the French project for a European alternative to the American "star wars" or Strategic Defense Initiative (SDI) programme, seems to be in a much better state — politically speaking — than it was a few weeks ago. Or so French sources are making out, now that the British foreign minister, Sir Geoffrey Howe, has indicated to his French counterpart M. Roland Dumas that he favours Eureka, despite initial British reticence.

The new British position seems to be that a variable-geometry, high-technology European programme, run by what the French describe as a "light" administration that would include the European Commission but not be controlled by it, could well be effective. Sir Geoffrey, it is believed, would like Eureka to concentrate on the "coordinated exploitation" of basic research. This is a logical insistence, as it is exactly what Britain alone has for long failed to achieve.

However, while Paris is now happy with London's support, and while administrations in many European states are now behind Eureka, contradictory statements and confusions about the project still abound, both between nations and between senior ministers of single nations, and particularly between France and Germany. Originally, German Chancellor Helmut Kohl had embraced SDI research in collaboration with the United States while French President François Mitterrand had rejected it, describing it as mere "subcontracting" and fearing a drain of technology and brains to the United States. But two weeks ago the West German foreign minister Herr Hans-Dietrich Genscher had visited the French capital and expressed doubts about star wars and enthusiasm for the Eureka project. Hopes were high for an agreement of last week's summit meeting between Kohl and Mitterrand at Lake Constance in Bavaria. In the event Kohl refused to abandon his support for SDI research, and failed to give any explicit backing to Eureka.

Afterwards, *Le Monde*, normally France's most respectable newspaper, launched an extraordinary front-page, and apparently politically inspired, attack on Kohl, describing him as provincial and vaccillating, and complaining that deep issues went completely over his head. But Mitterrand on Friday lowered the temperature greatly by describing Eureka as "a Franco-German idea", by claiming that it was of "vital necessity for West Germany" and that Germany agreed with this. Thus the waters muddy, and the true Eureka is hard to find.

At least the French view is becoming sharper. For example, M. Hubert Curien, the research minister, has now clearly confined M. Mitterrand's "non" to star wars to government actions and government support, and left industry free to decide for itself whether SDI involvement would pay. In practice, then, as countries that have said "yes" or "ja" are unlikely to be enthusiastic about SDI research if it involves the spending of large amounts of government money (unless that government is American), there may be little difference between the French and other positions.

In further clarification, Curien last week made the longest public statement yet on the precise nature of Eureka. He claimed it was well received in Rome, Copenhagen and Berne as well as in London (and Bonn), and promised the first "one or two" real programmes by the end of the summer. He was at pains to emphasize the need for industrial involvement in defining programme content and objectives, and said that such consultations were well under way. As to what the programmes will be, Curien remained curiously silent.

Robert Walgate

In vitro fertilization

Travemünde

MOST participants at this year's meeting of West German physicians (Deutscher Ärztetag) believe that the absence of legal guidelines in modern reproductive medicine should be made good by their own initiative. Fertilizations outside the mother's womb now occur in a "legal vacuum".

The physicians resolved to adopt professional rules (*Richtlinien*) to decide between correct and incorrect behaviour. Their unanimous opinion was that such rules should not be left solely to politicians and lawyers. Although it was also clear that many physicians have no wish to play a decisive role in *in vitro* fertilization, their demand was refused that there should be a stop to the programme until the inherent complications are understood.

The final communique was described by some as a presumptuous attempt by physicians to force their morals on the rest of society, particularly the restriction of the new technology to married couples.

Supporters of the restriction, however, hold that marriage and the family are the more relevant legal and ethical values, and that exceptions should be allowed only on the recommendation of a specially founded commission. Both sides agreed that the "rent-a-mother" (*Leihmutter*) concept is unacceptable, if only because of the risks of commercialization.

The physicians have taken this initiative now because the federal government is as slow and indecisive in this context as in that of recombinant DNA technology. One aim of the meeting was to put pressure on the government to clarify the legal position so that physicians are not left to decide alone. Jurgen Neffe

European defence programme

Ambitions of Heriot-Watt

WHILE European governments consider how to respond to American Secretary of State Casper Weinberger's invitation to join in star wars — otherwise the Stategic Defense Initiative (or SDI) — research, the SDI organization in Washington is not letting any grass grow under its feet. Last week, an SDI representative in England visited Europe's leading laboratory in optical computing at Heriot-Watt University in Edinburgh, and all but made an offer of a $150,000 grant, with a promise of several times that amount to come. In return Professor S. Desmond Smith and his team, who lead an eight-university European group created by the European Commission in Brussels to design the first all-optical computer, will join an American network working for SDI.

The Heriot-Watt group leads the world in this technology. In the past few months Smith and colleagues were able to demonstrate the first thee-element loop of optical switches operating at visible wavelengths at room temperature. This shows that "an indefinite extension of optical logic circuits is possible" said Professor Smith on Monday. Optical computing may offer not only speed but also enormous parallel processing capability, and is of much interest to SDI proponents, as it might make possible the rapid computations needed to identify, track and destroy multiple targets.

Is this the kind of loss of European high technology to the United States that the French had in mind in putting forward the Eureka programme? Not quite. "I'm here to build Europe", says Smith, "and if this grant is not going to help them I'm not going to use it".

For Smith, the lesson of this first SDI grant in Europe, which he described as "peanuts" compared with his collaboration's existing £2 million from British and European sources over the next three years, is that the US Department of Defense seems to spend not just for defence, but for the whole of American industry. This is exactly how US industry get into new technology so fast, Smith feels. By contrast, in seeking UK support to build prototypes of a working optical parallel processing system, Smith is finding that his requirement falls neatly between the Department of Education and Science, the Department of Trade and Industry and the Ministry of Defence. But in an exchange of letters with the Prime Minister, her chief scientific adviser, Sir Robin Nicholson, and others, Smith finds there is considerable support for an improvement in interdepartmental cooperation. Meanwhile, he is keeping closely in touch with the British government about the American approaches.

Research fraud

New ways of shading truth

Los Angeles

PRESSURE to publish and a lingering "pre-med syndrome" among medical researchers contribute not only to the relatively rare cases of outright scientific fakery, but also to various much more frequent abuses of scientific publication, according to medical researchers and journal editors speaking at the annual meeting of the American Association for the Advancement of Science.

Dr Edward Huth, editor of *Annals of Internal Medicine*, said that journals and scientific societies should consider adopting a precise definition of authorship to prevent one of the most frequent abuses, "false authorship". Other common abuses that he had encountered were the practice of slicing one study into a series — "salami science" — and repetitive publication.

Huth said false authorship usually occurs when a department chairman, laboratory technician or anyone not directly responsible for the intellectual content of the paper is listed as an author. Huth told of a case in which a researcher learned only by accident that his name had been included among the authors of a paper submitted to the *Annals*. While the researcher had provided some technical advice to the main author, at another institution, he had contributed neither to the design of the experiment nor to its execution, and had not even seen the final paper or any drafts. In fact, he had specifically declined an offer to be listed as an author.

Another common deception is statistical manipulation of data. Dr John Bailar, a statistical consultant to the *New England Journal of Medicine*, said that the deliberate misuse of statistics should be part of an "expanded definition of fraud". Inappropriate statistical tests have often been used to exaggerate the significance of the results presented. In some cases, authors seem to have tried several statistical tests, reporting only that which gives the best results. Hypotheses suggested by the data are often reported with *P*-values, which have meaning only for hypotheses formulated independently of data.

Huth suggested several steps that could be taken to curtail these abuses, which, he said, because of their "frequency and ubiquity", make them "more worth our attention than fakery". Although little can be done to prevent "salami science", repetitive publication could be checked by specifically asking reviewers to bring prior publications of the same material to the attention of editors.

False authorship may be more difficult to eliminate. The *Annals* requires each author to sign a form acknowledging that he has seen the final version of the paper and agrees to its publication. The shortcomings of even this approach were revealed by the case Huth mentioned above: the eight signatures on the forms bore a striking similarity.

Dr Robert Petersdorf, dean of medicine and vice-chancellor for health sciences at the University of California at San Diego, suggested that the problem lies deeper. Science has become "too big, too competitive, too entrepreneurial, too bent on 'winning' ". Federal research grants to medical schools have grown from $436 million in 1960 to $2,351 million in 1981, increasing proportionately much faster than enrolment.

Petersdorf said that the "pre-med syndrome" of intense competition and resorts to cheating carries through to competition for grants and for tenure, "eroding the moral fibre" of physicians.

The deputy editor of the *New England Journal of Medicine*, Dr Marcia Angell, suggested that grant-making agencies and tenure committees could help eliminate these abuses at source by refusing to consider more than the three articles a candidate considers to be his best in a given year.

Whether pressures to publish are responsible for the more serious cases of fraud remains unknown. Patricia Woolf, at the sociology department at Princeton University, noted that the number of papers published per scientist per year has changed little but in one group she has studied in detail (chemists), the number of "super-productive" researchers has clearly grown.

The National Institutes of Health (NIH), which investigates cases of fraud involving federal research grants, say that they receive about two reports a month of fraud or scientific misconduct, a minute fraction out of the 20,000 research projects active on any given day. Dr William Raub, deputy director for extramural research and training, said that NIH will nonetheless issue rules this summer requiring institutions that receive federal funds to report any cases of suspected fraud. **Stephen Budiansky**

Arianespace

Sky-high insurance unfair

ARIANESPACE, the largely French company that now runs Europe's Ariane space launcher on something approaching a commercial basis, is fed up with the huge insurance premiums that are being asked of satellite makers for launch on Ariane. According to M. Frédéric d'Allest, president of Arianespace, his company is being forced to pay for the losses made by insurers of the ill-fated Palapa B-2 and Westar-6 satellites, mis-launched from and then recovered the US space shuttle, and for recent failure of Syncom IV-3 and the earlier TDRS-A, also both shuttle-launched. Insurance premiums are now so high, 20 per cent of the capital cost of Arabsat, recently launched by Ariane, for example, that the growth of the satellite communications business itself is under threat.

According to Arianespace officials, before the shuttle setbacks premiums were set at around 6 per cent for a shuttle launch and 9–11 cent for Ariane. This was after Ariane had suffered two early failures, and reflected a feeling among the insurers that because the shuttle was manned, there should be less risk of uncorrectable trouble with a shuttle launch. But this did not take into account the large, multi-million dollar booster rockets needed by shuttle-launched satellites to take them from the low orbit of the shuttle up to geostationary heights, says Arianespace. This is the technology in which the shuttle has faced difficulties, while Ariane, which launches into an elliptical "geostationary transfer" orbit from which only a small "apogee motor" is needed to reach geostationary orbit, has gone from strength to strength. Ariane has now successfully launched 13 commercial satellites in its last eight flights, and it is time the insurers recognized the fact, says d'Allest.

But the insurance companies are reckoned to have lost almost $200 million on Palapa and Westar alone, despite their recovery, and another $85 million for Syncom, and they are fighting shy. Premiums are now around 18 per cent, with higher figures for those the companies think can pay, such as the Arabs. The premiums are the same for the shuttle and for Ariane, claims Arianespace, and they come as a package, making no distinction between the launch to first orbit (which the shuttle has accomplished perfectly) and the boost phase. M. Deschamps, director-general of Arianespace, would like the insurers to make a distinction by charging the same to Ariane and the shuttle for the first injection, and then more to shuttle customers for the boost, thus reflecting the apparently higher risk. At present the terms are "a brake" on growth, says Deschamps.

And Arianespace is certainly looking for growth, with 25 future satellites in the queue, an order book totalling FF 6,500 million (£600 million), a second launch pad at the launch site in Kourou, French Guiana, nearing completion and a third planned, apart from French space agency work on advanced and more powerful forms of Ariane, including a mini-shuttle, Hermes. And while President Reagan is attempting to shift more of the real costs of shuttle launches onto the customers, raising launch fees, Arianespace is planning to follow suit to raise profits, but not so much as to threaten the 30 per cent of the world market for satellite launchers the company hopes to be taking from 1987 on. Here is one field in which Europe feels at last that, for the time, it is holding one or two trump cards. **Robert Walgate**

European molecular biology

Computing facilities for EMBL

Brussels

PLANS to expand databank services, increase in-house and collaborative research and improve access by researchers to software and data at the European Molecular Biology Laboratory (EMBL) in Heidelberg have been given a first airing.

The idea for a European biocomputing facility, which would give the laboratory a greater coordinating role in Europe, was proposed by its director, Lennart Philipson, and was welcomed by scientists and science policy advisers, not only from Europe but also from the United States and Japan at a meeting to discuss developments in biosequencing in Italy last month.

EMBL's biocomputing programme involves the development and application of computing methods and a large-scale public nucleotide sequence databank, set up in 1981, which exchanges information regularly with the Los Alamos databank in the United States. The preliminary proposal outlined by Philipson would mean an overall expansion of computer operations and the setting up of a software library to enable remote users from all over Europe to screen data at EMBL, and to download them, together with the software, for local analysis. A data library is also envisaged which would collaborate with other databanks to supply protein, microbiological and gene-mapping data. The aim is not, however, to centralize all remote user computation but to act as a source of data and portable software for remote users. Computation would be mainly on a query and search basis, with EMBL providing a package of utility programmes for data screening, searching and manipulation. A software and data link-up with large national centres could also occur.

The facility would also carry out sequence analysis, developing methods and algorithms to interpret nucleic acid and protein sequences, basic research in the field of protein folding and engineering, modelling of proteins, protein-nucleic acid interactions and other more complex structures, biological graphics, image analysis and the development and maintenance of a user-oriented system and database for the analysis of two-dimensional electrophoresis. Finally, the facility could constitute a forum both for research and for the elaboration of software policy.

The expansion would require EMBL to increase staff and invest in more high-level hardware. The laboratory already has plans to install a VAX 8600 cluster core by the end of this year to which further VAX computers could easily be added. The added functions would, says Philipson, require an extension of hardware. Preliminary estimated costing of the proposal puts capital expenditure at DM 7.3 million and annual operating expenses at DM 3.2 million.

According to Philipson, the needs could be covered by a 10 per cent increase in the current budget. At present the 12 to 14 countries participating in the laboratory (including non-EEC countries such as Sweden, Finland and Israel) contribute a total of DM 38 million to EMBL's annual budget of DM 45 million.

Extra funds for space and hardware increases could be found in two ways: by contracts involving some of the interested countries or from the European Community, says Philipson. While some countries need and welcome European cooperation in this field, others, such as the United Kingdom, have been less keen to contribute in the past, preferring to build up activities on a national level. Whether the venture will be taken up in the laboratory's second scientific programme, which will run from 1987, will depend very much on several meetings that have been planned by EMBL's Scientific Advisory Committee and, ultimately, the EMBL Council. The next meeting of the advisory committee is scheduled for three weeks' time.

Anna Lubinska

US research support

Defence money no panacea

Los Angeles

UNIVERSITIES in the United States are in for a disappointment if they expect to reap a windfall from a new Department of Defense (DoD) initiative to support academic research. The "University Research Initiative" proposed in this year's Pentagon budget is, in fact, largely a symbolic step even in the eyes of Pentagon research chief Leo Young; Young's predecessor, George Gamota of the University of Michigan, speaking at the meeting of the American Association for the Advancement of Science, noted that when DoD began a similar programme to support university instrumentation three years ago, expectations ran so high that the $30 million a year programmes received $600 million worth of proposals.

Young said that the new initiative would help to overcome a "perception" problem dating from the passage of the so-called Mansfield amendment in the late 1960s. This rider on the defence appropriations bill requires all DoD to research support the mission of the agency, and has often been blamed for dwindling DoD support of basic research in the 1960s and 1970s and for continuing to prevent DoD from entering into a closer partnership with universities. Gamota, however, believes that the amendment has been used as an excuse within the Pentagon for not increasing basic research funds — particularly by those who wish to see other programmes funded.

The new initiative would provide $25 million, evenly divided between the Army, Air Force and Navy research offices and the Defense Advanced Research Projects Agency, for graduate fellowships, instrument purchase and young investigator awards. The House Armed Services Committee has recommended increasing that figure to $200 million, but the Senate has approved the lower figure. The Pentagon is proposing a total basic research budget for next year of $971 million. Historically, about one-half to two-thirds of that money goes to universities.

Existing programmes that support some 300 graduate fellowships, as well as the $30 million a year instrumentation programme, would continue even without the new initiative — and despite the Mansfield amendment. Young noted that the current version of the amendment provides a wide loophole by allowing research with a "potential" for supporting the Pentagon's mission "in the opinion of the Secretary of Defense".

Stephen Budiansky

Soviet pay rises

SOVIET scientists, designers and production engineers will from next year receive higher wages and more generous bonuses. But the resolution of the Community Party Central Committee, the USSR Council of Ministers and the All-Union Trade Union Confederation, which established the new pay scales in mid-May, made it clear that the purpose of the reform is to reduce the time spent in research and development, and in the implementation of new technologies, the endemic bottle-neck of Soviet civil industry.

Under the new scheme, managers of enterprises and organizations will be empowered to pay supplementary salaries and bonuses to persons responsible for "creative contributions" to new technology. Bonuses will be more closely linked to the "economic benefit" produced by the new technologies, and several measures have been proposed to improve the system of granting "author's certificates" (the Soviet equivalent of patents) and of making the attendant payments to scientists and technologists. Proposals to establish two new honorific titles: "Meritorious Designer" and "Meritorious Production Engineer", were also approved.

Although the new pay system seems to be aimed initially at applied scientists and technologists, it will almost certainly produce some spin-off for those working in basic research. During the past decade, there has been increasing emphasis on the need to strengthen links between academic research and production, and on the coordinating role of the Academy of Sciences in ensuring that research results are quickly implemented.

Vera Rich

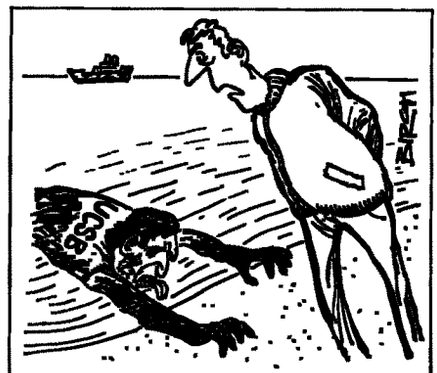
University of California

Oil disquiet at Santa Barbara

Los Angeles

THE University of California at Santa Barbara (UCSB) is about to build 65 new faculty houses with spectacular views of the Pacific Ocean, nearby beachfront and modern conveniences, all within walking distance of campus. But university officials are worried that professors attracted to their seaside campus might be disappointed. The reason is that UCSB has rich oil deposits in its front yard. An oil company plans to erect two giant drilling platforms in shallow water only a mile and a half away from campus and from the new faculty housing. And it is not just the view that is being threatened: the university's marine scientists fear that a marine study-preserve in the waters off campus could be harmed by the mud produced in drilling.

UCSB chancellor Robert A Huttenback seems reconciled to development of some kind, but says that the way it is done may be crucial. "If the air gets mucked up, the research environment could be ruined. The university could lose its appeal to students and faculty."



Everyone agrees the project will go ahead. The state of California is eager to lease the offshore tract to Atlantic Richfield (Arco), a Los Angeles-based oil company, because the state expects to earn between $600,000 and $1 million a day when the facility reaches peak production in 1992.

Arco has held its lease on the tract since 1945; but has only recently discovered the major new oil deposits. The Santa Barbara Channel and nearby Santa Maria Basin, most of which are under federal control, are expected to become the second largest offshore oil development in the Western hemisphere. Six other oil companies hold leases off Santa Barbara's coast but only Arco's is in the university's front yard.

The project calls for two double platforms to rise about 14 stories above the ocean floor and will produce from 80,000 to 500,000 barrels of oil a day. Plans for treating and transporting the crude oil and natural gas are under discussion.

On campus, likely winners include the structural and ocean engineers who will participate in designing new offshore platforms. Most worried are the marine scientists. Those affected by the project bring in over $5 million a year to the university in outside grants.

Aquatic biology has 1,450 undergraduate majors and 148 graduate students, making it the nation's largest marine sciences programme for undergraduates. Pioneering work has been done on abalone culture, bioluminescence, kelp reproduction and sediment transport. A specialized seawater system pumps water into laboratories and classrooms.

Not another oil-slicked Marine Biologist!

Because of their stake in the waters off campus, UCSB scientists are trying to convince state authorities that the usual legal requirements for protecting the environment are not enough to safeguard the area for research purposes.

Will toxic drilling muds damage the marine habitat? A preliminary study, paid for by the chancellor's office, indicates that such muds are detrimental to juvenile but not adult organisms. There is worry the muds might kill young abalone and other species and also foul the seawater intake system To quell such fears, Arco has said it might barge drilling wastes ashore to avoid contamination.

The university also fears there will be a housing shortage caused by the influx of workers. Rents are already high and the school will have to increase financial aid so that students can afford to live nearby.

But aesthetic concerns top the list. The campus is only two miles from the Santa Barbara airport and some professors are already bothered by helicopters taking off every 15 minutes or so as part of the overall oil development taking place in the region. Oil platforms, no matter how well built, strike many people as ugly. And their operations do sometimes emit foul-smelling odours that even now (from other oil rigs seven or more miles offshore) waft across campus a couple of times a month.

The views of the university are important to Arco, according to Robert Flaherty, a company vice-president. Nobody in the industry would produce oil and gas at the price of damaging UCSB's educational and research activities, he says. "We can't see the remotest possibility of these terrible effects."

Sandra Blakeslee

Franco-Japanese voyage

Hitch mars start for *Nadir*

Tokyo

NO sooner had the French research vessel *Nadir*, with the deep-sea submersible *Nautile* riding piggy-back, set sail on 1 June on the second phase of the Franco-Japanese deep-sea project Kaiko than mishap struck with an accident that injured two French crewmen, one of them seriously They were struck by flying metal from a ring that broke when testing the crane used to lower *Nautile* from the mother ship. Two relief crew are being flown out to Japan. Once they are on board, the *Nadir* will immediately set sail again on its three-leg cruise to explore the plate boundaries running along the deep-sea troughs and trenches off the coast of Japan.

The accident aboard the *Nadir* must add to the worries of Kazuo Kobayashi, Japanese co-director of the project, whose worst nightmare is that the *Nautile* will collide with a ship when she surfaces. The seas off the Pacific coast of Japan are criss-crossed by some of the busiest shipping lanes in the world and, near the junction of the Japan and Kuril trenches, where the cold southward-flowing Oyashio current meets warm air masses from the south, fog is frequent. As the *Nautile* has a cruising speed of only one knot, extensive surveys of currents in the study areas have been carried out before the survey to avoid unnecessary "drift" of the submersible during its planned two-hour descent to 6,000 m. Transponders placed on the bottom will allow navigation with pinpoint accuracy and the submersible can be directed by telephone to spots of interest by the mother ship. Time on the bottom will be about five hours at 6,000 m during which the submersible can traverse about 9 km of sea floor The three-man submersible will carry only one scientist at a time, so French and Japanese researchers will take turns to descend.

The temporarily delayed voyage is due to finish on 19 June after exploring the Tenryu Canyon and Zenisu Ridge which flank the Nankai Trough — a sediment-filled basin that straddles the boundary between the Eurasian plate on which Japan rides and the subducting Philippine plate which plunges beneath Japan.

The second leg, from 22 June to 10 July, will traverse the Suruga and Sagami troughs that cut into the Japanese mainland at the leading edge of the subducting Philippine plate. *Nautile* will then investigate Dai-ichi Kashima Kaizan, a Fuji-sized seamount that is being sliced and swallowed up by the Japan Trench (*Nature* 313, 433; 1985). On the final leg, from 13 July to 1 August, a seamount in a similar predicament will be investigated at the junction of the Japan and Kuril trenches, and it is hoped to make the deepest dive to nearly 6,000 m.

Nautile may also find subduction-zone analogues of the "vent communities" of giant tube worms and clams found at spreading centres, but here associated with cold seeps of methane rather than hot sulphur-rich waters (see *Nature* 313, 339; 1985). No biologists, however, will participate in the dives, which will be manned by geophysicists, geologists and geochemists.

David Swinbanks

Polish education

Threat of repressive new law

THE current clampdown on the academic community in Poland could seriously imperil Polish hopes of regaining Most Favoured Nation status (MFN) with respect to the United States. Loss of MFN, as part of the package of sanctions imposed by the United States when General Jaruzelski imposed Martial Law in December 1981, has cost an estimated $50 million in Poland's foreign trade earnings. Alleged government plans for the deployment of graduates, recently described by the underground Solidarity journal *Tygodnik Mazowsze* could well render this loss permanent.

According to *Tygodnik Mazowsze*, new legislation is being drafted jointly by the Ministry of Science and Higher Education and the Ministry of Education to ensure that all "graduates" work for ten years in the nationalized sector of the economy. "Graduates", the paper explains, apparently quoting from a leaked draft of the proposed legislation, includes all "Polish citizens who have completed basic vocational schooling, secondary vocational schooling of all types, higher education or who have taken PhDs abroad". If such persons fail to work in the nationalized sector for at least ten years after graduation, they may be asked to return to the treasury the cost of their education. As a corollary, "graduates" who have not completed this ten years' service, if going abroad, will be required to deposit the cost of their education as a guarantee of their return.

The last requirement appears to contravene the terms laid down in the US Senate by the Jackson-Vanik amendment (law 504A) of 1974, under which the US government is forbiden to grant MFN to any other government which requires intending emigrants to repay the cost of their education. According to the extracts of the draft quoted in *Tygodnik Mazowsze*, implementation of the proposed law is expected to bring into the treasury several hundred million zloty a year from the contributions of graduates to the nationalized sector, as well as forfeited "guarantees".

In addition to the MFN problem, the implementation of the law could seriously damage Poland's international image. The new law would apply for 15 years after the end of their studies. This would seriously hamper the prospects of younger Polish scholars wishing to travel abroad for, even if they intended to return, they might not be able to pay the deposit. Linkage of higher education with employment contravenes the international human rights law.

The extension of the term "graduate" to cover the trade-school sector could hit not only small craftsmen, but also the run-down private agricultural sector. Since 1980, the Polish government has given various grudging guarantees to the private farmers (who account for some 75 per cent of all Polish agriculture) that no attempts will be made to force them into the system of state and collective farms. The government has reluctantly agreed the principle of a scheme, proposed by the Catholic Church, to raise agricultural capital abroad and, according to Fr Alojzy Orszulik, the press spokesman of the Polish Catholic hierarchy, the government negotiators are about to "finish their work" on the plan. The rumoured new law would, however, mean that graduates of agricultural academies and agricultural secondary schools could return to their family's farms only in middle life. The foreign patrons of the Church scheme (who include the governments of the United States and the European Communities) may well be given pause.

Vera Rich

Failure for West German Greens

LAST month's election in Nordrhein-Westfalen (NRW), the most populous state in the Federal Republic, was a great success for the Social Democratic Party (SPD). It comes exactly halfway through the legislative period of the Christian Democratic (CDU) Liberal (FDP) coalition government in Bonn and is widely regarded as a vote against the coalition policies. Equally important was the failure of the Green Party to obtain the 5 per cent vote necessary to win seats in the NRW parliament.

The Green Party fared less well than it had hoped in the election in Saarland three months earlier, where it obtained only 2.5 per cent of the votes. The 4.6 per cent in NRW was not a significant improvement on the result five years ago, when the Greens were a completely unknown factor.

Coalition with the SPD was made impossible by the Greens' determination that NRW should withdraw completely from the nuclear industry. But, like the CDU/FDP in Bonn, the SPD in NRW has a strong interest in maintaining, among other nuclear power stations, the nuclear research centre at Jülich and the fast breeder reactor at Kalkar. It seems the FPD has now adopted enough of the political standpoint of the Green Party to weaken its appeal to ecologically minded voters.

Immediately after the election, an old quarrel broke out within the Green Party between the fundamentalists and realists. The former oppose all political compromises, while the latter strive to exert direct political influence. The difference between the two factions is so basic that it may splinter the Green Party. The three established parties may henceforth need take less notice of new radical ideas.

Jürgen Neffe

Indian cooking

Chulhas win fair wind

New Delhi

CHULHAS (wood stoves) that do not emit smoke and use less wood are fast replacing traditional cooking stoves in rural households, ushering in a "smokeless revolution" in India's countryside.

Some 800,000 smokeless chulhas have so far been installed and 5,000 villages have become smokeless in 15 months since the project was started by the Department of Non-conventional Energy Sources (DNES). The project has exceeded expectations, says DNES secretary Maheshwar Dayal, whose department has fixed a target of five million improved cooking stoves by 1990.

About 40 per cent of all the energy in India is used for cooking food. The traditional woodstoves made of mud and brick in India's 112 million homes annually burn 133 million tonnes of firewood and over 200 million tonnes of cow-dung cake. But the stoves are so inefficient that rural women spend long hours collecting firewood. The improved cooking stoves, with a combustion efficiency of more than 15 per cent, have drastically cut down consumption of firewood. And because these stoves are designed to burn the fuel completely, the kitchens are smoke-free. Dayal says that smokeless chulhas introduced have saved 600,000 tonnes of firewood. By 1990, the saving would be 4.2 million tonnes, valued at Rs 2,940 million (£210 million).

Some 29 models of improved cooking stoves have been developed and introduced by social organizations and research institutions such as the Indian Institute of Technology (IIT) in Delhi, the Central Power Research Institute (CPRI) and the Indian Institute of Science (IIS) in Bangalore. The cooking stoves vary according to the region, type of food cooked and fuel used. But all new designs are tested and certified by testing and training centres at IIT, CPRI and the Punjab University of Agriculture in Chandigargh.

While fixed-type chulhas are installed by government agencies and voluntary organizations, portable models are marketed at prices ranging from Rs 38 to Rs 63 (£3 to £5) by 12 private companies that have sprung up to cash in on the smokeless revolution. As an incentive to buyers, the government has abolished excise duty on fuel-efficient wood-burning stoves.

DNES has also developed community chulhas capable of cooking for up to 200 persons, with fuel efficiency as high as 35 per cent, recommended for hostels, hotels and canteens. The Tamil Nadu state government is planning to install the improved community chulhas in the 33,000 schools whose midday meal project is being threatened by firewood shortage.

K.S. Jayaraman

Oceanography

Sino-Japanese collaboration

Tokyo

IN the wake of successful cooperation between the United States and Japan in oceanography, Japan's Science and Technology Agency has recently revealed plans for joint research with China in a multi-million dollar long-term study of the East China Sea and the Kuroshio, a huge warm ocean current in the Western Pacific that affects fishing, weather and shipping.

Although details are still under negotiation, the project will start in March 1986 and run for seven years The chief participants will be Japan's fishery, meteorological and maritime safety agencies and China's National Bureau of Oceanography.

The project, which was proposed by China in "vague" terms two years ago and put into more concrete form by Japan, will follow on from a 10-year study of the Kuroshio sponsored by the Science and Technology Agency That survey, the Kuroshio Exploitation and Utilization Research (KER) project, is due to end next year but has only covered a small area of the East China Sea, a politically sensitive region for oceanographic research because of its potential oil reservices.

The Kuroshio (black stream, black because of its low reflectivity) is a 100-km wide "river" of clear warm water originating east of the Philippines that flows north past the eastern coast of Taiwan and then winds its way along Japan's Pacific coast before turning abruptly out into the Pacific on meeting the southward-flowing cold Oyashio current. At this bend in the Kuroshio, the Kuroshio Extension, huge swirling eddies of warm water extending to depths of hundreds of metres break off from the main stream and head slowly north, often persisting for periods of more than a year before finally being absorbed into the Oyashio or reattached to the Kuroshio.

With a speed of 3-4 knots and a volume transport of 30-60 tons per second the Kuroshio represents a tremendous potential source of energy, a point not missed by energy-hungry Japan; one purpose of the KER project is to assess the viability of harnessing the Kuroshio's power. But the real power of the Kuroshio lies in its influence over Japan's fisheries.

In the East China Sea, the current creates one of the world's largest fishing grounds and is an important spawning area for several commercial fish such as sardines. According to a KER report published in March, vast numbers of fish eggs are spawned next to the temperature/salinity front of the Kuroshio and eggs and larvae are picked up by the current and transported hundreds of kilometres downstream to nursery grounds off the Pacific coast of Japan. In addition, fish such as tuna and bonito feed along the length of the Kuroshio and the warm eddies north of the Kuroshio Extension can cause switches in the migration routes of several commercial fish such as Pacific saury Japan's vast fishing industry thus has a tremendous vested interest in understanding the vicissitudes of the Kuroshio. In fact some large tuna fishing vessels are already equipped with automatic picture transmission equipment for receiving and processing real-time infrared satellite images of the Kuroshio. As such equipment is beyond the resources of all but the largest fishing vessels (a terminal costs about $65,000) the Japan Weather Association (JWA) introduced a satellite data service in October last year which provides HRPT (high resolution picture transmission) infrared imagery data in photographic or floppy disk form for as little as $4.60.

Satellite-monitoring both of drifting buoys and sea-surface temperature will also form an important part of the joint project with China, according to Dr Hideo Nishida of the Hydrographic Department of the Maritime Safety Agency. The annual budget for Japan's contribution to the project will be similar to that of KER, he said, more than Y100 million ($0.4 million).

At the same time as the Science and Technology Agency's project gets under way in the East China Sea, the Ministry of Education-affiliated Ocean Research Institute (ORI) of the University of Tokyo intends to tackle the other end of the Kuroshio, focusing attention on the warm core rings north of the Kuroshio Extension. Professor Takahisa Nemoto, head of the Plankton Division at ORI, announced at an international seminar here in Tokyo this week that a cruise of the institute's RV *Hakuho Maru* will study Kuroshio warm core rings in September 1987, while the institute's smaller research vessel, the *Tansei Maru*, will carry out preliminary studies in the same area in 1986.

France

Future of encyclopaedia in doubt

THE creation of a great new French encyclopaedia, mostly of the sciences, was announced by the present French government in 1982. It was to use all available new technologies (databanks, electronic access, video) as well as trhe more traditional ones (print) and it was to be the 20th century's answer to the *Encyclopédie Diderot*, the great enterprise of the Enlightenment to encompas all knowledge in a few fat volumes. Where it is now? Appealing, it seems, to the French public for a few sous. A new advertisement has appeared in Paris asking for "patrons" to invest in the new encylopaedia, which, until recently at least, has been unable to attract a French publisher willing to carry any financial risk.

The publishers North-Holland, it is hoped in Paris, may produce an English version, but the *Commission Diderot*, which is in charge of the 20th century masterwork, needs to raise another FF 10 million (around £1 million) to bring this "encyclopaedia of living questions" to the French. It will be interesting to see if the French will be willing to pay. So far the commission has a grant of some FF 750,000 from the ministries of education, research and culture, and has been promised a further FF 4 million from industry. That not being enough, the appeal appears to have been the only way forward.

So will the encyclopaedia, the brain-child of present education minister Jean-Pierre Chevènement (who was research minister at its launch), be worth a minimum of FF 100 investment? The French market is not large and the publishers' judgement should be respected. But FF 100 to be associated with a great project?

The encyclopaedia is certainly great. 200 volumes are expected by the end of 1989, and the first 20, involving 200 authors, are promised by April 1986. But its structure is novel and even contradictory. The principle is that "knowledge" is not fixed but changing; and moreover that at any time there can be many opinions on a subject. While this may be true of many ideas, there are also many of which it is not true. And it is difficult to see how a flux is to be fixed in encyclopaedic form.

In practice, the *Commission Diderot*'s strategy was to send out a nation-wide "appeal for questions (this came before the appeal for funds), an appeal which led to a list of 350 (such as "will carbon-dioxide emissions alter the climate and by how much?") out of which the commission has selected some 50 for the first volumes. Some 80 per cent of the questions received were in the physical or biological sciences or in mathematics, and only 20 per cent in the social sciences (which surprised the commission secretariat). Answers to these questions by the 200 authors will form a resource, it is said in Paris, from which many kinds of publication may be drawn. A great deal depends, therefore, on these authors, who must produce texts which are "intelligible to all" and address all the fears and hopes raised by the subjects they cover.

According to Dominique Lecourt, shortly after he was appointed director of the project, the encyclopaedia is to be "a powerful instrument of liberation". It will also "reject any attempt to assemble the sum of all knowledge or to present it according to an apparently rational order" It is a mountainous and confusing task, and it must be asked if even France is large enough to face it — even with a few more sous.

Robert Walgate

Lobbying of NSF denied

SIR — In "US engineering research: Six special centres founded", (*Nature* 11 April, p.488; 1985), Tim Beardsley reports on several grants made by the National Science Foundation (NSF) to establish major engineering research centres. At the end of the article, Beardsley implies that political influence was involved in the selection of one of the awardee institutions. This letter's erroneous implication could cause great potential harm.

Beardsley states: "At least one US senator had lobbied NSF to locate an engineering research centre in his state, apparently successfully. But Bloch [Erich Bloch, director of NSF] insists that siting decisions had been made exclusively on the basis of peer review of the 142 proposals from 106 institutions."

The only communication about this matter that NSF received from the senator concerned was a form letter asking for information about the proposal on behalf of a constituent. That would hardly seem to constitute "lobbying" even by the most rigid of definitions.

Beardsley apparently reached his conclusion after reading a press release issued by the senator's office that seemed to imply a greater involvement. Other writers attending the press conference about the awards correctly identified this as a case of a political figure being overzealously associated with an event beneficial to his constituency. Beardsley's statement beginning, "But Bloch insists " does not help matters greatly.

NSF goes to great lengths to ensure that decisions on all proposals are made on the basis of scientific merit and that the scientific and engineering communities are aware of and confident in that fact. In the case of the engineering research centre proposals, the review involved a four-stage process in which a number of competent persons participated, including highly respected engineers from academia and industry. Let me state clearly that politics was not and is not part of the process. The implication in the Beardsley article to the contrary is most unfortunate.

RAYMOND E. BYE JR
Office of Legislative and Public Affairs,
National Science Foundation,
Washington, DC 20550, USA

Tim Beardsley writes: While there is no evidence that NSF's reviewing was influenced by political pressure, the form letter referred to, from Senator Alfonse D'Amato of New York, was sent to NSF in response to a request for support from Mr Gregory Fusco, vice-president of government relations at Columbia University. The senator's involvement was readily confirmed by his office at the time the story was written. Senator D'Amato asked NSF to keep him informed of the progress of Columbia University's application and asked that Mr Fusco's request "be given every consideration". Some might disagree with Mr Bye's assertion that this does not constitute lobbying (*Oxford English Dictionary*: "to seek to influence"). Only the over-sensitive, however, would object to the word "insists" in connection with Bloch's denial that political factors influenced the selection process; insisting that one is innocent carries no implication that the opposite is true.

Embryo research

SIR — In their attempt to establish a status for the *in vitro* fertilization embryo, which denies the scientific understanding of the human embryo and the medical code of ethics in regard to it, Drs Evans and McLaren make some remarkable points[1].

They castigate Professor Lejeune because he ". . omits to say that research on the detection and prevention of these genetic defects... in some instances can only be done at this early (embryonic) stage" while omitting to point out themselves that most developmental genetic research work can be and is being done on ethically suitable animal and insect models. Indeed, *Nature* is organizing an international conference ("Genes and Systems in Development", San Francisco 7-9 October 1985) "to address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?" Most of the papers are based on animal models.

When the normal developmental processes of pattern formation are understood, then the abnormal processes can be solved — for how can one hope to understand the pathological without a proper understanding of the normal? In regard to the use of insect embryo models for understanding genetic development, David Ish Horowicz has suggested a relatively short time span: "It is conceivable that within 5 years it will all be over. We will have solved the universal biological problem of pattern formation"[3]. Allowing a further five years to solve the question of abnormal pattern formation (genetic defects), the answers should be available before the turn of the century. In the meantime, we can console ourselves in the knowledge that infants with genetic defects comprise less than 1 per cent of live births and 993 out of every 1,000 embryos, which implant with genetic defects, will not result in a live birth[4].

Women students

SIR — In his article, "Women in science and engineering", (*Nature* 2 May, p.84), Richard Pearson suggests that the cause of the surprisingly low representation in the "less traditionally heavy engineering" field of electrical engineering and electronics may be that "the competition for places is much harder in these subjects".

Surely this implies that women engineers are simply not as able as men in the field of electrical engineerng and electronics, and therefore cannot compete for these jobs?

I find this an extraordinary suggestion from a member of the Institute of Manpower Studies, but comparable to the engineering careers consultant at my old university who advised all female engineers to become accountants.

ELIZABETH FISHER
42 Salisbury Avenue,
Cheam, Surrey SM1 2DJ, UK

SIR — In Richard Pearson's article on sexual discrimination (*Nature* 2 May, p.84) there is an important difference between what is purported to be the percentage of medical students in the United Kingdom who are women, and what the government believes the figure to be. Pearson's Table 1 gives 49 per cent as the percentage of first-year women medical students in 1982 (a figure he attributes to the Universities Central Council on Admissions). The Department of Health and Social Security publication *On the state of the public health for the year 1983* (HMSO) gives the percentage number of women entrants in UK medical schools in 1982-83 as 44 per cent, and for the previous year 43 per cent. Whom do we believe? Medicine being what it is, I imagine the DHSS figure is nearer the mark.

Avoiding recurrent catastrophes

The death of perhaps 15,000 people in Bangladesh last month was caused by cyclonic and tidal forces in concert. Prevention may be impossible, but better warning is essential.

THE tragic loss of life in the Ganges delta of Bangladesh two weeks ago will never be accurately quantified. Even in normal circumstances, the numbers of people eking out a living in the delta can only be guessed at; the numbers of those swept away by the tidal wave that filled the Bay of Bengal on 25 and 26 May will be counted only imperfectly. But tragedies like this recur at frequent intervals along this low-lying coast. What can be done to prevent them, or at least to mitigate their effects? Understanding the phenomenon must be a first step, which is why there is interest in a calculation of the interaction between wind-driven surges and the natural tide in the Bay of Bengal, published in the *Philosophical Transactions of the Royal Society* (**A313**, 507-535; 1985) by B. Johns of the University of Reading and associates from the Indian Institute of Technology at New Delhi: A.D. Rao, S.K. Dube and P.C. Sinha.

In the long run, accurate prediction of these tidal waves must be a prerequisite for avoidance action. Two weeks ago, the meteorological services did warn of impending trouble along the low-lying coast, although the argument continues whether the warnings might have been fuller. Too fatalistically, people also ask what value broadcast warnings may be to people too poor to own radio receivers.

The essence of the phenomenon that killed about 15,000 people in the Bay of Bengal is that by which a cyclonic pressure may create a surge of water elevation as it moves through shallow water onto the shore of an enclosed tidal basin. The first expectation is that the increase of water level and thus the risk of flooding will be greater when the arrival of a cyclone coincides with high tide. But by now it is accepted that the interaction between the tides and the wind-driven surge is not linear. The whole may be greater (and more damaging) than the sum of the parts.

Johns *et al.* have provided a valuable snapshot of where the modelling of tide/surge interactions now stands, and also of what remains to be done. The paper sets out to model retrospectively the tidal wave that hit the low-lying coastal strip of the Indian state of Orissa, on the west of the Bay of Bengal on 3 and 4 June 1982. When more is known of the track of the cyclone that drove last month's tidal wave onto the coast of Bangladesh, the same mathematical apparatus may be used to reconstruct that sequence of events as well.

The technique is in principle straightforward. First, the bottom topography and the coastline of the bay are represented by smoothed curves. This is the idealized but still realistic basin in which the water is driven by the forcing of tidal oscillations in the Indian Ocean, and by the surface winds of cyclones. But because of the large volume of water in the several mouths of the Ganges, one elaboration of the model puts a series of 200-km stretches of water at the head of the bay.

The hydrodynamic equations for the motion of the water in the bay are simplified to the case of a flat surface, although the Coriolis forces associated with rotation are allowed for. The coupling between the Indian Ocean and the bay is supposed to be determined primarily by the astronomical tides, whence arises the most immediate difficulty of the model: by what conditions should the interaction be represented on the boundary, taken as an imaginary line running east from the Sri Lankan coast? In principle, if there were enough tidal stations around the bay, it would be possible to determine this external forcing function accurately, simply by running the model and comparing its predictions of the tides with observations of them in normal circumstances. In the event, the data are so sparse that Johns *et al.* can do no more than represent the tidal effect of the Indian Ocean on the bay by means of a regular sinusoidal variation of height with constant phase along the whole length of the arbitrary boundary. If catastrophic surges in the bay are to be predicted accurately, this needless simplification must be avoided, from which it follows that much better tidal data must be collected from many more stations in the bay.

Incorporating cyclones in the model is also an empirical process. The chief physical effect is that of cyclonic winds on the sea surface. Johns *et al.* represent the Orissa cyclone by a wind-field modelled to allow for decreasing velocity with increasing distance from the centre, but fitted with the crude meteorological data available for the cyclone. By their account, the predicted height of an induced surge in the Bay of Bengal will depend sensitively on the wind-field pattern out to 100 km or so from the centre of the storm, which points to another obvious difficulty: because there is at present no way of inferring precise wind-speeds from synoptic meteorological data, real-time predictions are, for the time being, uncertain.

In the circumstances, it is remarkable that the model functions as well as it does. By forcing the movement of the mass in the bay by the crude representation of the effects of the external tide, as well as by the Orissa cyclone following its measured track, Johns *et al.* conclude that the average height of the tidal wave in June 1982 may indeed have reached 8 m at some parts of the coastline. But given the unavoidable arbitrariness with which the constants specifying the wind-field must be chosen, the real proof of the pudding is that the model seems to have reconstructed the sequence of events correctly.

The Orissa inundations of 1982 turn out to have been interesting in their own right (but perhaps they all are). According to the model calculations, not much seems to have happened to the level of water off the Orissa coast (except for a gradual rise totalling 2 m in a day) until the centre of the cyclone made its landfall on the afternoon of 3 June. Thereafter, however, the computer calculations bear out such anecdotal evidence as there is that the largest elevation of sea-level occurred some hours later, further to the north-east. During this interval, the model shows, it is almost as if a tidal wave was moving steadily along the coast from the point of landfall, at first increasing with height. The tidal and cyclonic effects are not additive, which is what would be expected of solutions to a set of equations which are inherently nonlinear, but the result is that some odd things can be expected. The times of maximum inundation may differ by several hours from those of high tide. Parts of the coast far from the point of landfall may be inundated twice.

Directly, none of this has much to do with last month's tragedy. Indeed, the physical scale of these phenomena is so great that outright avoidance is clearly beyond reach. The only realistic way of mitigating recurrent damage on last month's scale is that there should be more accurate warnings, and that better use should be made of them. Much might be done by running the model of Johns *et al.* not merely on those cyclones which turn out to be damaging, but on the much larger number of meteorological depressions in the Bay of Bengal which turn out to be relatively benign, for then it might be possible to build up a kind of taxonomy of dangerous cyclones. But for such an exercise to be worthwhile, better tidal observations are essential.

John Maddox

Neurosciences

Modulation of some deadly sins

from Charles F Stevens

SEVERAL recent articles, three of them elsewhere in this issue, shed light on neuromodulation, the shadowy side of brain function. We understand quite well in terms of cellular mechanisms about half of what the brain does — the integration and transmission of information. But the other half — the neuromodulatory systems that seem to mediate, for example, glutony, sloth, lust and anger, if not more of the seven deadly sins — is only now beginning to be elucidated.

The well understood part of brain function has been revealed through a line of research initiated by Hodgkin, Huxley, Katz, Kuffler and Eccles. Integral membrane proteins, known as channels, control the permeability of the neuronal membrane to ions, and thus regulate the brain's electrical activity. The channels change their conformation in response to synaptically released neurotransmitters or variations in membrane voltage. These conformational changes cause the channels' transmembrane pores to open and permit ionic current to flow across the neuronal membrane. The neurotransmitter, the first messenger, thus triggers the current flow that acts as a second messenger by producing changes in membrane voltage in remote parts of the neurone, where the behaviour of other channels is in turn altered. The number of distinct kinds of channels is quite large: neurones have at least a dozen species of channels that sense membrane voltage, and more than a dozen types that open their pores after binding specific neurotransmitter molecules such as acetylcholine, dopamine or serotonin.

Neurotransmitters are released at the brain's 10^{13} synapses, and part of their function is to cause channels to open. But some neurotransmitters also have a quite different function that is not yet fully understood. They bind to receptors on the neuronal surface and employ chemical second messenger systems, rather than current flow, to produce myriad effects. A typical second messenger is cyclic AMP, produced by neurotransmitter-activated adenylate cyclase. Second messengers in the brain have a wide variety of effects, ranging from the ability to alter the rate of transcription of specific genes (see, for example, Barinaga, M. *et al. Nature* **314**, 279; 1985) to the modification of channel properties, as described below. The hallmark of these modulatory effects is that they involve covalent modification of proteins rather than simple conformational changes, and thus occur on a time scale of seconds to minutes or longer, whereas the typical channel opening and closing that is responsible for the nerve impulse, for example, occurs in the order of milliseconds.

The three papers on neuromodulation in this issue involve three different types of channels that respond to membrane voltage by opening pores selective for potassium ions; more than half a dozen distinct types of potassium channels are known. On page 501, Aghajanian reports that the neurotransmitter noradrenaline causes the suppression of one species of potassium channel ('A' channels) in neurones of the dorsal raphe nucleus. Because the normal function of this channel is to slow the production of nerve impulses, the suppression results in an increase in the rate of firing. Stanfield, Nakajima and Yamaguchi report on page 498 that the neuropeptide substance P suppresses a second type of potassium channel (the inward rectifier), so increasing the excitability of neurones cultured from the globus pallidus. Finally, on page 503, Ewald, Williams and Levitan demonstrate the mechanism by which cAMP increases the activity of a third type of potassium channel (the calcium-activated potassium channel). Using patch clamping of isolated membrane patches from nerve cells of the snail *Helix* and channel reconstitution in artificial lipid bilayers, they find that the action of the catalytic subunit of cAMP-dependent protein kinase increases the probability that the channel will open. Their observations demonstrate that the substrate of the kinase is either the channel itself or a closely associated entity. Similar experiments by Shuster *et al.* (*Nature* **313**, 392; 1985) have shown that the cAMP-dependent protein kinase can act to decrease the activity of a fourth type of potassium channel (the S channel), which is implicated in a form of learning in the sea slug *Aplysia*. Although various types of potassium channels are frequently the targets for neuromodulation, other channels are also influenced in this way. For example, DeRiemer *et al.* (*Nature* **313**, 313; 1985) recently showed that the action of a channel that controls calcium permeation is augmented when the enzyme protein kinase C is activated.

Why does the nervous system go to so much trouble to modify channel properties? One of the brain's chief powers is that it is self-modifying — one set of computing elements can, under neuronal control, be substituted for another while the basic nerve cells and their connections are maintained. Channel properties determine the information handling capabilities of neurones; altering them changes the way information is processed.

Even though we know that neuromodulatory phenomena are both common and important, we are only now starting to define the range of effects and the underlying mechanisms. In no case has the entire regulatory cascade been fully elucidated and much more must be done to work out enough specific examples before we can begin to perceive the underlying logic. Discovering how the brain modifies its own machinery is one of the most important challenges in modern neurobiology and is becoming one of the most active areas of research. □

High-energy astrophysics

Is Cygnus X-3 a source of gamma rays or of new particles?

from Alan Watson

IF NEW results from the Soudan proton-decay project[1] are being interpreted correctly, cosmic, rather than man-made, accelerators are providing evidence either for a new elementary particle or for unexpected interactions of existing ones. The cosmic accelerator in question is the well-known X-ray and radio source, Cygnus X-3. By observing gamma rays above 10^{15} eV, groups at Kiel[2] and Leeds[3] universities have identified Cygnus X-3 as one of the most powerful emitters of charged cosmic-ray particles in the Galaxy[4,5]. These groups have shown that a few high-energy air-shower events from the direction of Cygnus X-3 display the distinctive 4.8-h modulation seen at X-ray and TeV gamma-ray energies. Because of the continuity of the spectrum from 10^{11} to 10^{15} eV (refs 2,3), and in the absence of other straightforward explanations, it has been generally assumed that these signals are gamma rays resulting from π^0 decay in the environs of the source. The new results from proton-decay experiments in the Soudan mine[1] and in the Mt Blanc tunnel (NUSEX)[6] challenge this simple picture and may demand a change in our views about particle physics.

Cygnus X-3, one of the most luminous X-ray sources in the Galaxy, is a stellar-binary system some 12 kpc from the Sun[7] in which a neutron star orbits a more massive companion star. X-rays are emitted when gas flowing from the massive star falls into the deep gravitational potential well surrounding the neutron star. The X-rays are modulated with a 4.8-h period which slowly lengthens and which is believed to be the orbital period of the system

— the minimum of the X-ray signal defines zero phase, $\phi = 0$, and is thought to occur when the neutron star is eclipsed by its companion. Signals, interpreted as gamma rays, have been seen regularly in many independent experiments from 10^{11} to 10^{16} eV, as discussed previously in these columns[8]. Here, the pattern of emission is variable but relatively sharp spikes of emission (of width $\Delta\phi \lesssim 0.1$) have usually been seen near $\phi = 0.2$ and/or $\phi = 0.65$. Nuclei accelerated in the electromagnetic fields of the neutron star may generate π^0s, and hence gamma rays, through interactions in the circumstellar material[5]. Above 10^{11} eV, cosmic-ray primaries are detected through the cascades that they produce in the atmosphere. It is an inference to say that gamma rays have produced the showers, but neither charged particles nor neutrons could be the primaries — the interstellar magnetic field is much too turbulent for the former to retain their original direction or phase coherence, whereas neutrons of 10^{15} eV have a mean path length before decay of only 30 pc. It has long been expected that gamma-ray initiated air showers should be deficient in muons by a factor of about 10 compared with proton showers, because the photopion production cross-sections are 100 times smaller than proton-proton cross-sections. In an attempt to secure the gamma-ray identification, the Kiel group[9] searched for signals from muons above 2 GeV in a shielded 65 m^2 detector within their array. It came as a shock that for the 14 'on-source' events for which they had data, the muon content was about 80 per cent rather than about 10 per cent of that in 'off-source' events: were the primaries really gamma rays? This difficulty was recognized but tended to be dismissed because the Kiel detector could not follow muon trajectories.

In this context the recent work by the Soudan group[1] demands attention. It is the first published report of a remarkable effect, apparently duplicated in the NUSEX experiment[6], which has hitherto been known only to readers of the *samizdat* literature of particle physics. The Soudan and Mt Blanc groups operate large volume proton-decay detectors at depths of 1,800 and 5,000 metres water equivalent, respectively. Both find that those straight tracks which pass through their detectors (interpreted as single muons) and which project back close to the Cygnus X-3 direction, exhibit its distinctive 4.8-h periodicity. In the Soudan experiment the enhancement of 600 GeV muons is in the phase range $0.65 < \phi < 0.90$ and consists of 84 ± 20 events, whereas for NUSEX the excess of 1 TeV muons comprises 19 ± 5.7 events in the interval $0.7 < \phi < 0.8$. The possibility of chance giving the observed distribution in each experiment is estimated separately to be between 10^{-3} and 10^{-4}.

If Cygnus X-3 is a gamma-ray source, with the rays originating from π^0 decay, then it must also be a neutrino source; both the Soudan and Mt Blanc groups have considered the possibility of neutrinos as muon parents. The Soudan group find that the local zenith angle distribution of events in the phase peak is similar to that of ordinary muons and claim that they can reject completely the hypothesis of an isotropic zenith angle distribution expected for neutrino primaries. In the NUSEX experiment, the predicted neutrino-induced muon flux is too low by a factor of about 800 to explain the observations. To explain the Soudan results, Marshak *et al.*[1] propose either a new interaction or a new neutral particle. To maintain phase coherence, such a particle must have travelled from Cygnus X-3 with a Lorentz factor above 2×10^4.

But some worries about the new experiments remain. The Soudan effect is maximized in a direction displaced by about 3° from the known radio position of Cygnus X-3, which is rather more than can be accounted for by uncertainties in the horizontal orientation of the detector. It is not clear that the background calculation correctly accounts for the possibility of variable exposure at different phases throughout the experiment. In particular the background summed over all phase bins is not equal to the source count as it should be for the background calculation described (J. Lloyd-Evans, personal communication). In the NUSEX analysis a $10° \times 10°$ area centred on the source has been required to maximize the signal; this is much larger than the $1° \times 0.5°$ error in celestial coordinates estimated for each particle track. The absence of any signal above 7 TeV also needs explaining. In neither experiment is it clear whether any statistical degrees of freedom remain unaccounted for in the probability estimates.

As a final twist to this complex story the Akeno air-shower group has just announced a result[10] agreeing with conventional views of the muon content of gamma-ray showers. In air showers with less than a thirtieth of the normal number of muons they find a 4.8-h modulated signal from Cygnus X-3 above 10^{15} eV and at phase 0.5-0.6. Both the phase and intensity agree with recent work from Haverah Park (A. Lambert *et al.*, manuscript in preparation), where confirmatory evidence will be sought with the University of Nottingham's new 40 m^2 muon detector. At the moment the gamma-ray interpretation of Cygnus X-3 is the simplest hypothesis and it may be premature to reject it. □

Plant metabolism

Coping with drought by the sea

from Peter D. Moore

CRASSULACEAN acid metabolism (CAM) is a photosynthetic strategy characteristically associated with plants subjected to periodic or constant water stress. It is therefore, more usually described in plants of arid lands and with continental distributions than in those found in oceanic areas. It is particularly surprising that a recent study by P.P. Daniel *et al.*[1] of *Umbilicus rupestris* (wall pennywort) — a distinctly oceanic member of the Crassulaceae — should have revealed that this plant exhibits a physiological response to drought that is reminiscent of CAM.

During the past century it was observed that some succulent species of plants accumulate acid in their tissues during the night, but it was not until the 1940s that the full significance of this behaviour was understood. Leaf acidification is accompanied by the nocturnal uptake of carbon dioxide and it has become clear that there is a temporary fixation of carbon by the enzyme phosphoenolpyruvate carboxylase into a 4-carbon compound, oxaloacetate, which is subsequently converted to malate. In the daytime, the malate is decarboxylated and the released CO_2 is refixed by the Calvin cycle enzymes. The main advantage of the pathway is the opportunity it provides for water conservation, because the stomata in the leaf need only open for gaseous exchange at night when transpiration losses can be kept to a minimum.

The efficiency of water conservation in CAM plants becomes clear when their transpiration/photosynthesis ratios (grams of water transpired per gram CO_2 fixed) are compared with those from plants that have other photosynthetic strategies[2]. For CAM plants the ratio is usually 50-100, for C_4 plants it is 250-300 and for C_3 plants 400-500. The strategy is also efficient at conserving carbon, as the CO_2 generated by respiration can be trapped and retained in the same manner.

One of the costs of efficient water conservation in CAM plants is a fairly slow rate of carbon accumulation in the growth of tissues. Therefore, there are clear energetic advantages in the adoption of a flexible system in which it is possible to switch to CAM only during periods when it is of advantage to the survival of the plant, such as in times of water stress; several species of plant have now been described that can do this[3]. One is the succulent *Mesembryanthemum crystallinum*[4], found on

sandy shores and sand dunes around the Mediterranean. Other species switch to an incomplete form of CAM when they experience drought. This has been termed 'CAM idling'. In this mode, there is no fixation of atmospheric carbon during the night, but there is a nocturnal accumulation of acid resulting from the fixation of respiratory CO_2. Here, carbon economy is closely linked to water conservation.

It is this type of CAM idling that has now been observed in *Umbilicus rupestris* when it is exposed to drought. Under normal well-watered conditions, *Umbilicus* behaves like a conventional C_3 plant as far as its carbon exchange is concerned, taking up atmospheric CO_2 during the day and showing a net output of CO_2 at night. After six days of drought, the daytime uptake becomes confined to a short period in the morning, after which stomatal exchange is curtailed. The plant makes up the reduced carbon intake by lowering the respiratory losses at night when phosphoenolpyruvate carboxylase traps the CO_2 generated in respiration and converts it to oxaloacetate and then malate, resulting in tissue acidification.

Evidently the falling water potentials in the plant activate a metabolic switch, but the nature of the operation of this switch is still unknown. One of the consequences of switching is the enhancement of carboxylase enzyme activity; Daniel *et al.* have shown that the properties of the activated enzyme are somewhat modified — for example, it is less sensitive to low *p*H and to malate inhibition[5]. But they do not suggest the generation of a new separable form of the enzyme.

There remains the intriguing ecological question of why an oceanic species should possess this unusual capacity for dealing with drought. The answer must lie in its preferred habitat, for *Umbilicus rupestris* is a plant of cliff crevices and stone walls,

Wall pennywort growing epiphytically on a date palm in Seville, southern Spain.

and sometimes even grows as an epiphyte on larger plants. It can be found at the southern extremities of its range in southern Spain growing on the coarse trunks of the date palm, *Phoenix dactylifera* (see figure). In such exposed locations, often with little or no true soil around its roots, the risk of drought must be very real for *Umbilicus*, even in the wetter regions of north-west Europe. Clearly, the capacity to switch to CAM idling enables the plant to make the most of any given set of conditions. Discovery of CAM in an oceanic temperate plant forms an interesting equivalent to the tropical epiphytic ferns in which CAM has previously been described[6]. □

Particle physics

Look before you LEP

from David J Miller

THE physics agenda for the large electron-positron machine (LEP), now being constructed at the European Organization for Nuclear Research (CERN), was first circulated in the late 1970s. At that time the Z^0 and $W^{\pm}$ were entirely theoretical particles, but they were needed by the electroweak theory of Glashow, Salam and Weinberg to carry the weak part of the force. Now that these particles have both been discovered by experimenters using the proton-antiproton ($p\bar{p}$) collider at CERN, and after the other developments of the past six years, what should the goals of LEP be? John Ellis convened a Physics Jamboree at CERN on 19 March 1985 to examine this question. Similar answers came from the five working-groups that reported: we must test the validity of the standard model theories at energies where they might begin to break down, and we must probe for the explanation of their many arbitrary parameters.

The important feature of an electron-positron (e^+e^-) machine like LEP, compared with the existing $p\bar{p}$ collider, is that there are no spectator particles to complicate the main event. Although Z^0 and $W^{\pm}$ particles can be found in $p\bar{p}$ collisions, thorough investigations of their properties will only be possible with an e^+e^- machine. Guido Altarelli (Rome) reviewed the precision studies that can be made when the e^+e^- energy is around 94 GeV, equal to or just above the Z^0 mass. In this energy region nearly all reactions will go via a resonance centred at the Z^0 particle and LEP becomes a 'Z^0 factory'. Every possible pair of particle and antiparticle into which the Z^0 can decay will be produced at roughly comparable rates — for example, the heavy tau leptons, the rare and heavy beauty quarks or the everyday down quarks. Although the rarer quarks and leptons are much heavier than the common ones, their partner neutrinos all seem to be very light, so the Z^0 could decay to particle-antiparticle pairs of new neutrinos that are the partners of still undiscovered quarks and leptons. This should allow us to prove the number of generations of heavier and heavier sets of quarks and leptons that still remain to be found after the 'beauty-top-tau' generation. Altarelli reported a technique which the LEP experimental teams believe they can use to make a definitive measurement of the number of neutrino types, and hence the number of generations, since there seems to be one neutrino per generation. This would require only ten days of experimental running when LEP has achieved its planned beam intensity.

Although the Stanford Linear Collider (SLC) in California, now also under construction, may be the first e^+e^- machine to produce the Z^0, its initial detector will probably not be good enough to make this particular measurement. Some of the other physics around the Z^0 mass will probably be investigated first by SLC groups, but it will require very patient and precise work to check all the predictions of the electroweak model — particularly to measure the higher-order corrections to its fundamental constant, the Weinberg angle. Here, the cross-checks between SLC and the four LEP experiments will be important.

Wilfred Buchmuller (CERN) described the feasts in store when we finally pass the toponium threshold — the energy at which toponium, a bound state of a top quark with an anti-top quark, can be created. Last year the UA1 experiment at the $p\bar{p}$ collider gave an estimated mass for the top quark of between 30 and 50 GeV, but no independent confirmation has yet appeared for this rather imprecise result. Toponium may therefore be found anywhere from the present limit of 43 GeV, set by the experiments at the PETRA e^+e^- collider in Hamburg, to the highest possible LEP energy. It should have many of the properties of the two well-established positronium-like quark-antiquark states, the J/psi (charm-anticharm) and the upsilon (beauty-antibeauty). Although toponium should have more excited states than the J/psi and the upsilon, all but the lowest of them will be impossible to resolve, even if they lie well below the Z^0 mass. If they lie close to the Z^0 mass, the physics could be extremely complicated since the Z^0 and toponium states would behave like nearby resonances coupled to the same input channel. They would have opposite phases, so toponium would appear not as localized bumps in the cross section but as narrow dips on the

shoulder of the larger Z^0 bump. Because of the greater mass of the top quark, toponium will be a smaller system than either J/psi or upsilon, and its detailed level-structure will give evidence for the behaviour of the quantum-chromodynamic potential at very short range. Other ways of investigating quantum chromodynamics in e^+e^- annihilation and the scattering of virtual photons from virtual photons, were reviewed by Ahmed Ali (DESY, Hamburg).

The totally new effects that might appear once the natural energy scale of the weak interactions is reached were reviewed by John Ellis (CERN). The cause of the large masses of the $W^{\pm}$ and Z^0, together with the generations of heavy quarks, is one of the great open questions in current theory. These masses may be generated by the Higgs-Kibble mechanism, which introduces a new heavy scalar particle that pervades space, modifying the vacuum and coupling most strongly to the heavy particles. No one has yet identified corresponding free Higgs bosons, although many strategies to look for them have been suggested, especially in Z^0 or toponium decay. But other more complicated theoretical schemes exist which would not necessarily need simple Higgs particles. If their thresholds are reached at LEP, the effects may be seen in anomalous events like the UA1 monojets, which some have tried to explain in terms of supersymmetric theories (see J. Ellis, *Nature* **313**, 626; 1985).

Herwig Schopper, the director-general of CERN, announced that he plans an early upgrading of LEP from the initial (50 + 50) GeV LEP 1 machine, which starts work in 1989, to the (100 + 100) GeV LEP 2. The only change needed would be to replace the accelerating radiofrequency cavities. Great progress has been made in developing the required superconducting cavities and some of them will even be included in LEP 1.

Schopper's announcement was particularly interesting after the discussion of the physics to be done at LEP 2 energies (Roberto Peccei, DESY). The bankable study, which cannot be done on any other machine, is to produce W^+W^- pairs directly via the fundamental couplings of electroweak theory. This gives yet another probe of higher order corrections. If the Higgs particle has not yet been seen, it will only be through such higher order electroweak studies that we will be able to differentiate between the different candidate models that generate masses. There is also more speculative work to be done at the higher LEP 2 energies, continuing the search for the effects of supersymmetry or for some new heavier scale of composite substructure that may underlie the present particles. The Jamboree showed that LEP has an even longer list than before of important specific questions to answer. If there are surprises as well, it will be a bonus. □

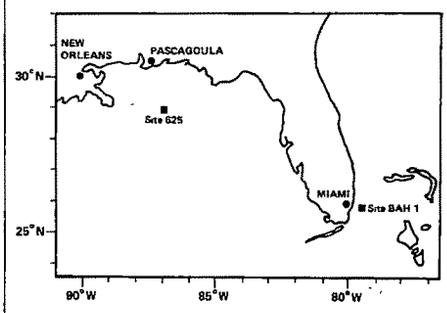
Ocean Drilling Program

Shakedown and sea trials

*from the Leg 100 shipboard scientific party**



THE Ocean Drilling Program (ODP), successor to the Deep Sea Drilling Project (DSDP), commenced its field operations on 11 January 1985 with an 18-day shakedown and sea-trials cruise (Leg 100), departing from Pascagoula, Mississippi and arriving at Miami, Florida. The cruise came after an extensive conversion and overhaul of the newly chartered drilling vessel *Joides Resolution*. This drillship is 470 feet long and 70 feet wide with a displacement of 16,596 tons, a derrick towering 217 feet above the waterline, and the ability to employ a drillstring of 30,000 feet (9,146 m) in water depths up to 27,000 feet (8,632 m).

Prior to the shakedown cruise, a seven-storey main laboratory structure, geophysics laboratory and a separate library and study area were constructed aboard the vessel. Additional scientific, office and storage space has been provided; major modifications to the ship's dynamic positioning system, which enables the vessel to maintain a relatively fixed position over the hole being drilled in the sea bottom, now enable long-based and short-based line systems, as well as the original ultra-short-based line system, to be used. The system is supported by 12 powerful 750 horsepower thrusters, as well as by two main shafts each with six 750 horsepower motors. In addition, a 400-ton heave compensator, which keeps the drillstring stable relative to the seafloor, has been installed. These are only a few of the numerous modifications made to the original rig.

The science laboratories contain a complete array of seagoing research equipment that will allow shipboard scientists to carry out a wide range of physical and chemical analyses on the core samples recovered by drilling. There are laboratories to study sedimentology, physical properties, palaeomagnetics, chemistry, gas analysis, palaeontology, petrology, thin section, X-ray diffraction and fluorescence microscopy, scanning electron microscopy, and downhole measurements. In addition, facilities for photography, electronics, and refrigerated core storage are available. While the ship is in transit between drill sites, digital single-channel seismics are recorded and processed in the on-board geophysics laboratory. There is also a research-oriented computer system which is designed to perform as many routine clerical and arithmetical tasks as possible. A pair of VAX computers serve as a central processor and data library for 50 microcomputers distributed throughout the laboratories.

During the inaugural cruise, three holes were drilled at site 625, near De Soto Canyon, west Florida Shelf (see figure). The scientific objectives were to document the sedimentological, palaeontological, geochemical, geotechnical and geomagnetic characteristics of the sedimentary sequences, and to correlate alternating sedimentary and erosive sequences to worldwide changes in sea level over the past several million years. The principal operational objectives were to test the rotary advanced piston coring (APC), and extended core barrel (XCB) drilling and coring systems, and to familiarize the drillship's crew with core handling and sampling procedures.

The deepest of the three holes drilled was 625B, which penetrated to 235.2 m subbottom. This hole was continuously cored with the APC system through 197.1 m of Plio-Pleistocene section. The XCB sytem continued to termination depth in the Lower Pliocene. At the third hole (625C), an attempt was made to obtain a complete section of the uppermost Quaternary by overlapping the HPC cores taken in the previous hole between 5 and 44.5 m sub-

Location map for site 625.

bottom. A visual comparison between the overlapping piston cores indicates that the sequences in each are closely matched. On the basis of physical properties and magnetic susceptibility data, we believe that no more than about 10 cm of material remained unsampled after the double HPC coring. Since this operation was accomplished in hostile sea conditions, it clearly demonstrates the usefulness and importance of the heave compensator.

During Leg 100, the onboard scientific, drilling and operational equipment was tested under varying sea conditions and generally performed to, or even exceeded, expectations. A fairly large number of adjustments or rearrangements of equipment were required but the minor nature of these is illustrated by the fact that the ship was able to depart on 31 January, after only two days in port, for the first fully operational, internationally staffed cruise of the Ocean Drilling Program, Leg 101. □

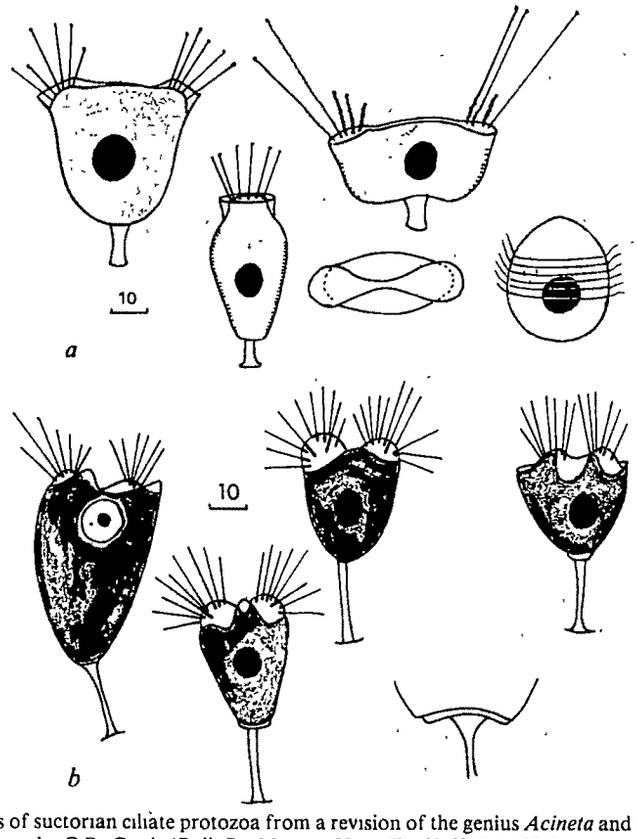
Split-gene evolution

Exon shuffling and intron insertion in serine protease genes

from John Rogers



EVER since the discovery of split genes, there has been a debate about why they are split. This can be resolved into three separate problems: the origin of the introns that split the genes (separating exons from each other), the role of introns in evolution, and their present function, if any (for example, refs 1–3). Ideas on these matters can be tested against the serine proteases (proteins that have particularly clear patterns of domains[4,5]) now that more than a dozen of their genes have been sequenced. In agreement with one hypothesis, the different domains are encoded in separate exons, some of them apparently transferred from unrelated genes. But it is also clear that new introns have been inserted at various times in evolution.

Discussions of the role of introns in evolution have centred round ideas of 'exon shuffling', in which exons are supposed to be units in the evolutionary rearrangements of genes[1-3]. One should bear in mind that exon shuffling, however advantageous in the long run of evolution, cannot explain the origin of introns, nor does it amount to a present-day function for them. Nevertheless, there has been considerable interest in the idea that some exons encode protein domains, or at least coherent structural motifs, which would be good material for evolution by exon shuffling. Thus, they could be subject to duplications within a gene, as has happened in several genes such as that for fibronectin[6,7] (and the serine proteases — see below). In addition, exons could be transferred between unrelated genes to create new proteins out of old domains. Attempts to validate this more interesting possibility have not been successful. For example, the nucleotide-binding fold of metabolic enzymes is not encoded separately[2,8], and the amino-terminal signal peptide of secreted proteins, which is often more or less contained in a single exon, is too variable in sequence for its ancestry to be reliably traced. But good evidence of exon shuffling is now available from the exon/intron organization of the serine protease genes.

The serine protease superfamily[4,5] includes digestive enzymes (such as trypsin), enzymes of the blood-clotting and complement cascades and various other polypeptide-processing enzymes such as the kallikreins. (To escape from the semantic jungle of 'pre', 'pro' and 'gen' terms, I use the names of the active forms of these molecules.) New serine proteases have been arising by gene duplications for most of biological history. Those just mentioned probably diverged more than 500 million years ago, and there are even more divergent homologues in bacteria[5,9]. The protease domain itself is activated by cleavage from a larger precursor. The non-enzymatic portion often includes various structurally distinct domains with particular physiological functions.

Exon shuffling is best illustrated in the 5′ halves of the dozen sequenced genes, as shown in the figure. In each case, the coding region outside the protease domain is split by at least one intron in phase I of the reading frame (see figure) and the various extra domains within the region are encoded by separate exons or groups of exons, also separated by introns in phase I. It is presumably this coincidence of phasing that has permitted the assembly of diverse exons and the tandem duplications of some of them. An example is the kringle domain (so named because of its topological resemblance to a traditional type of Scandinavian cake). The region of the gene that encodes the kringle, flanked by phase I introns, has been duplicated independently in the genes for thrombin[10], tissue plasminogen activator[11] and plasmin[12] (not shown). This has happened even though the domain has different internal splicing patterns in these three genes[10-12] (intron insertion?), and even though the donor splice site following the kringle seems to have been replaced by a splice site that is nine codons further downstream in the gene for uPA, another serine protease[13] (intron sliding).

The tPA gene contains another two exons which, as reported by Ny *et al.*[11], provide the first example of exon transfer between otherwise unrelated genes. The third coding exon, unique to tPA, encodes a disulphide-linked 'finger' that is homologous to the tandemly repeated 'fingers' of the fibronectin molecule[14]. In fibronectin, each 'finger' is encoded in a separate exon[6], and although their boundaries have been mapped only approximately, the one example sequenced[6] does have a potential splice site in a position precisely equivalent to that in tPA. Thus, the tPA exon seems to have come from a fibronectin gene. The fourth coding exon of tPA encodes a region of homology to epidermal growth factor (EGF)[11,14]; a homologous exon is duplicated in the gene for clotting factor IX[15]. This exon may have come from a gene like the EGF gene, which contains several EGF-like segments in separate exons (G. Bell, personal communication); but any firm conclusion must await the sequencing of the EGF gene. Even further back, the fibronectin-related and EGF-related exons of all these genes may have had a common origin, as all three exons encode sequences approximating to Cys-

X-Cys-X-X-$^{Gly}_{Asn}$-X-X-Gly-X-X-Cys near their 3′ ends[14].

The domain that encodes the protease activity itself sheds light on the origin of introns. As in several other superfamilies, the positions of introns are different in different genes, and the question is whether this results from insertions or excisions. Clearly introns can be excised, at least in mammals[1,16,17]; that they can also be inserted, at least in invertebrates, is suggested by the apparently random positioning of introns in invertebrate gene families such as actin[16] and myosin[18], but this idea has never been proved. The different serine proteases, which are also pre-vertebrate in origin, show an unambiguous history of intron insertions (see figure).

This is clearest within the trypsin family (middle five lines in the figure), the family tree of which, as deduced from protein sequences, is shown at the left. These genes all have three introns in common. As one follows the branches of the family tree, new unique introns appear in the different genes — one extra in tPA and uPA, two extra in chymotrypsin and three extra in elastase. It seems that the shared introns were also inserted, as the introns in the trypsin family are entirely different from those in thrombin, and almost all are different from those in complement factor B. Such unrelated patterns could hardly have arisen by random deletions of introns. Therefore, most or all of the introns in the protease domain have been inserted. (The only apparent exceptions are the two introns of the factor IX protease domain, which match introns in elastase and factor B, respectively. But according to the amino-acid homologies, the first of these is in a segment that may have come from a chymotrypsin- or elastase-like gene by recombination, while the second is in a region of weak and uncertain relationships.)

Given that these introns have been inserted, do their positions show us anything about how or why this happened? Some regularities can be discerned. For one thing, the figure suggests that new insertions tend to occur near the middle of pre-existing exons. Thus a gene evolves towards a uniformity of exon size. This has been noted independently for the elastase gene[19] and for genes in general[8,20]. Another regularity[3,21] is that many of the introns map to surface loops, and particularly to variable-length loops, in the protein structure. Craik *et al.* [3,21,22] suggested ways in which this length variation could be caused by the presence of the introns, for example by substitution of alternative splice sites (intron sliding). Another possibility now worth considering is that introns generate length variation because they are inserted inaccurately. As introns do not resemble any known transposable elements, one can speculate that a new intron might be included as part of a longer insertion, or might be induced when an insertion activates a cryptic splice site that is nearby.

Structures of the coding parts of serine protease genes. The family tree as deduced from protein sequencing[5,9,26] is summarized schematically at left, the dashed branches being tentative. FIX is human clotting factor IX[15]; THR, human thrombin[10] (gene structure not reported for regions shown dashed); tPA, human tissue plasminogen activator[11]; uPA, pig urokinase[13]; KAL, mouse kallikrein; TRY, rat trypsin (gene structures are identical for two trypsin genes[22] and four kallikrein genes, including nerve growth factor subunits[27,28]); CHY, rat chymotrypsin b[29]; ELA, rat elastase[19] (two similar genes); CFB, human complement factor B[30] (the exons shown are preceded by other, non-homologous exons); HAP, human haptoglobin[23]; Exons are shown as boxes shaded according to their homologies. Sequences with no discernible homology to each other are in black. Introns are not to scale, but their phase relative to the reading frame is indicated, according to whether they follow the first (I), second (II), or third (0) nucleotide of a codon.

On the other hand, some introns are in conserved coding regions, and these include some of the most striking cases of independent insertions into the same region. Thus, five genes in the figure contain an intron that is 14–21 codons into the protease domain, but at least three of these are in different positions relative to codons for conserved amino acids. Even more remarkable, the penultimate introns in complement factor B and elastase fall in the same conserved glycine codon, but one nuceotide apart. These coincidences cannot reasonably be explained by intron sliding; this would require vanishingly improbable coincidences of mutations in order to shift an intron within a conserved coding region, or to shift the phase of an intron. The non-random positions of these introns seem to imply either sequence specificity at the insertion, or selection following it, for reasons that are still mysterious. The methodological lesson, however, is clear. Correlation of introns with protein structure[1,8] does not, *per se*, tell us whether the introns are original or recent additions.

A final puzzle is presented by the gene for haptoglobin[23], a member of the superfamily but not known to have protease activity[9]. Although this gene has plenty of introns in its 5′ half, dividing duplicated phase I exons as in the other genes, there are no introns in the 3′ half, which encodes the protease-like domain. This could represent the condition of the ancestral serine protease gene, intronless-like genes of bacteria. Alternatively, it could represent a much more recent processed gene, derived from the messenger RNA of a split serine protease gene via reverse transcription, which became attached to a different split gene. A similar history has been postulated for part of the (unrelated) clotting factor VIII gene[24]; this mechanism has also been proposed as a general way of evolving new proteins[25]. Processed genes are common only in mammals[17], so if one is incorporated either in haptoglobin or in factor VIII, the gene from which it was derived may still be present and detectable by nucleic acid hybridization. □

Igneous petrology

Discordance in layered intrusions

from R.S.J. Sparks

LAYERED intrusions are the frozen remains of magma chambers. Their distinguishing characteristic is a vertical variation in mineral abundance, giving rise to a horizontal layering superficially resembling that seen in sedimentary rocks. The study of their geology and petrology has played a central role in the development of ideas on the origin of magmas. Intrusions such as the Skaergaard in Greenland provide almost perfect natural examples of crystallization under closed-system conditions. Other intrusions, such as Rhum in Scotland and Stillwater in Montana, record the history of long-lived open-system magma chambers. The classic method of investigating a layered intrusion is to collect samples through the stratigraphy and to document variations in the composition and abundance of minerals. Usually one vertical section has been taken to represent the entire intrusion. In a recent paper, J. R. Wilson and S. B. Larsen[1] describe the first comprehensive two-dimensional study of a layered intrusion — the Fongen-Hyllingen intrusion in Norway. The relationships they report provide important new facts which any theory on the origin of layered intrusions must seek to explain.

Detailed geological mapping and systematic petrology provide the key to understanding large layered intrusions, which typically cover areas of hundreds of square kilometres. This kind of study is thus a substantial and time-consuming enterprise. Indeed a layered intrusion often becomes associated with one particular scientist who may have devoted considerable time to its study; perhaps the most notable link is between L.R. Wager and the Skaergaard intrusion. Wilson and colleagues at Aarhus University in Denmark have devoted over fifteen years to investigating the Fongen-Hyllingen intrusion and they have now produced one of the most significant studies of a layered intrusion for many years.

The variation in mineral composition observed in these intrusions is termed cryptic layering, whereas the presence or absence of minerals defines the phase layering. On the scale of outcrops, the layering is made visible by small changes in the relative abundances of minerals, here termed modal layering. Wilson and Larsen document dramatic lateral variations in mineral composition and show that the modal layering observed in the field is strongly discordant to crytpic and phase layering.

The Fongen-Hyllingen intrusion was emplaced as a sill-like body at 12-20 km depth during the Caledonian orogeny, roughly 425 Myr ago. The intrusion and its metamorphosed envelope of basic and pelitic country rocks are now part of a nappe complex and prolonged erosion has exposed a longtitudinal cross-section 33 km in length. The northern part (the Fongen and Ruten Series) has the greatest stratigraphical thickness (6.2 km) and is complicated by folding. Primitive ultramafic rocks occur at the base of the sequence and there are many reversals in the mineral compositions, a certain sign of an open-system magma chamber. The southern part (the Hyllingen Series) consists of 3.6 km of modally layered rocks, and is documented in detail by Wilson and Larsen.

Both the floor (the western margin) and the roof (the eastern margin) are exposed in the Hyllingen area. Geological mapping reveals intimate interfingering of country rock with layered rocks in the southern region. Swarms of huge country-rock inclusions, with individual metabasic xenoliths up to 1 km long and a few hundred metres wide, are found throughout the sequence. The layering is completely undisturbed by these xenoliths and they seem to be in their original positions rather than having fallen in from the roof or walls. The igneous rocks are highly evolved ferrogabbros and ferrodiorites, with quartz-bearing syenites occurring next to the roof. Minerals include olivine, Ca-rich and Ca-poor pyroxenes, amphibole, plagioclase, Fe-Ti oxides, zircon, apatite, biotite and allanite. The very high Fe/Mg ratio of ferromagnesian minerals shows that all the rocks have crystallized from highly differentiated magmas. In any one vertical profile four stages of magma evolution can be recognized. Stage I is an unlayered gabbro. Stages II and IV record initial open-system behaviour with relatively constant mineral compositions followed by progressive differentiation. Stage III in the middle of the sequence records a major reversal with minerals gradually becoming less fractionated towards the top of the section.

The most important results of the study are the recognition of lateral variations in mineral compositions, which are almost as great as those recorded in vertical profiles and provide evidence by changes of mineral abundances on millimetre or centimetre scales. These layers strike north-south, parallel to the floor and roof with no deviation at the southern contact or locally around enormous xenoliths. However, mineral compositions (defining cryptic layering) change dramatically along the strike with minerals becoming more evolved towards the southern margin. For example, at the boundary between stages III and IV the olivine and plagioclase vary from Fo_{75}: An_{63} to Fo_{13}: An_{42} over a 10 km strike length. The stage boundaries are parallel to field layering, showing that changes in the differentiation trend occurred simultaneously at the same stratigraphical level. With eleven separate vertical profiles Wilson and Larsen have been able to contour lines of constant mineral composition. The contours are discordant to the modal layering by angles which are typically 20° but are as much as 90° at the southern margin. As described in their preliminary account[2], boundaries recording the appearance of new cumulus minerals (zircon and apatite) are also highly discordant to the rhythmical layering.

Conventionally, the visible modal layering is thought to represent the trace of the ancient magma-chamber floor and therefore each layer is a time-plane. If this is so then the implication of the discordance is that the magma chamber must have been compositionally stratified throughout its evolution. Wilson and Larsen argue that the dramatic lateral gradients and the lack of disturbance of layering by xenoliths eliminate crystal settling. They believe that the crystals grew *in situ* along the floor. They propose that the floor was gently tilted so that increasingly differentiated magma in a zoned chamber was in contact with the floor in the (southerly) upslope direction. Thus, the minerals systematically change composition and new phases appear up the slope. Addition of magma from the north complicated the picture by elevating the zoned magma column and causing gradual reversals as lower and more primitive magma migrates up the slope. A more elaborate model, based on the work of Irvine, Keith and Todd[3], envisages lateral accretion of layers, in which the field layering, mineral-composition layering and the accretion front (the time-plane) are all discordant.

Recent petrological literature contains several new ideas on the processes that form layered intrusions. Several workers have argued that double-diffusive convection plays an important role[3-6]. There is also field and theoretical evidence that compaction of cumulate piles and post-cumulus migration of melt[7,8] can lead to changes in mineral compositions, which further complicates interpretations of their petrogenesis. Irrespective of the merits of recent thinking and speculation, the discoveries of major lateral variations and discordances in layered intrusions must be central facts on which different hypotheses will succeed or founder. Wilson and Larsen's work should herald a new phase of research in layered intrusions, in which documentation of lateral changes will be as important as vertical variations. □

Has inductive probability been proved impossible?

SIR—The interesting letter by Popper and Miller[1] and the subsequent correspondence[2-4] leaves in some doubt the question whether a proof of the impossibility of inductive probability been given. As this would be a remarkable achievement, it is no criticism of these authors that we raise this question again. In our view the answer is a clear "No". We shall follow your other correspondents in not burdening the discussion with references to extensive earlier literature.

The key elements in the Popper-Miller (PM) argument are: first the evidence e, when found, counter-supports the implication $h \leftarrow e$ of a hypothesis h by the evidence; and second, this is due to the negative nature of that part of the support for $h \leftarrow e$ arising from e which is not purely deductive. From this type of consideration, PM infer the impossibility of inductive probability. In both the original PM and the following discussion, the part played by the negation $\bar{e}$ was not considered explicitly. Yet it is helpful to do so in showing what is going on in these arguments, as will now be explained. Two basic results, to be formulated as "theorems", are useful preludes to this explanation.

Theorem A

$$\begin{aligned} p(h \leftarrow e|e) &\leq p(h \leftarrow e|e) + \underline{p(\bar{h}|e)p(\bar{e})} \\ &= p(h \leftarrow e) \leq p(h \leftarrow e|\bar{e}) = 1 \\ p(h \vee e|\bar{e}) &\leq p(h \vee e|\bar{e}) + \underline{p(\bar{h}|\bar{e})p(e)} \\ &= p(h \vee e) \leq p(h \vee e|e) = 1 \end{aligned} \quad (1)$$

Theorem B The following have the same sign:

$$\begin{aligned} p(h|e) - p(h) &= \underline{p(h|e)p(\bar{e})} - p(h|\bar{e})p(\bar{e}) \\ &= p(\bar{h}|\bar{e})p(\bar{e}) - \underline{p(\bar{h}|e)p(\bar{e})} \\ &= p(\bar{h}) - p(\bar{h}|e) \end{aligned} \quad (2)$$

and

$$\begin{aligned} p(\bar{h}|\bar{e}) - p(\bar{h}) &= \underline{p(\bar{h}|\bar{e})p(e)} - p(\bar{h}|e)p(e) \\ &= p(h|e)p(e) - \underline{p(h|\bar{e})p(e)} \\ &= p(h) - p(h|\bar{e}). \end{aligned} \quad (3)$$

Theorem A shows the origin of theorem 1 of PM that

$$p(h \leftarrow e) > p(h \leftarrow e|e) \qquad (\text{if } p(e) \neq 1) \quad (4)$$

as follows. The underlined terms are positive, so that (4) could be incorporated in (1). Note that $p(h \leftarrow e) = p(h \vee \bar{e})$ allows for the possibility of $\bar{e}$, which possibility is ruled out by the assumption that e has occurred. This makes the inequality (4) intuitive as a logical necessity (which is incidentally independent of any inferential relation between e and h).

Since $h \leftarrow e \equiv h \vee \bar{e}$, $\bar{e}$ must "support" $h \leftarrow e$ maximally, or $p(h \leftarrow e|\bar{e}) = 1$. It is intuitively to be expected, therefore, that e "counter supports" $h \leftarrow e$. These statements interpret Theorem A (an extension of theorems 1 and 2 of PM).

Theorem B shows relations between four "support" functions whose definition

$$s(h, e) = p(h/e) - p(h) \quad (5)$$

was introduced into the correspondence by Jeffrey[3]. They are shown as differences in different ways. Adopting the nomenclature of your correspondents (which is possibly misleading), we call the underlined terms "non-deductive". The introduction of negations is again helpful here, for they show, using (5), that the "non-deductive" part in (2) appears with a positive sign (support) in $s(h, e)$, but with a negative sign (counter support) in $s(\bar{h}, e)$. Similarly for (3). Thus the remark by PM that all probabilistic support is purely deductive requires some different definition of these terms or some restriction on their interpretation.

Theorem B also tells us something very reasonable about the function (5):

$$\begin{aligned} &s(h, e) \geq 0 \text{ implies } s(h, \bar{e}) \leq 0, \\ &s(\bar{h}, e) \leq 0,\ s(\bar{h}, \bar{e}) \geq 0 \end{aligned} \quad (6)$$

while $s(h, e) \leq 0$ implies $s(h, \bar{e}) \geq 0$,

$$s(\bar{h}, e) \geq 0,\ s(\bar{h}, \bar{e}) \leq 0 \quad (7)$$

In words, if e supports h then it counter-supports $\bar{h}$, and also $\bar{e}$ counter-supports h but supports $\bar{h}$. The converse is given by (7).

The above considerations explain, we hope, some of the results obtained by PM, by your correspondents and by us. They do not really go beyond basic facts such as: $h \vee e$ follows deductively from e, $h \vee \bar{e}$ follows deductively from $\bar{e}$, together with probability algebra. In that sense, they are obtained by strict deduction and have nothing to do with induction. It is for these reasons that we have to give the answer "No" to the question in the title.

J. WISE
P. T. LANDSBERG
University of Southampton
Southampton SO9 5NH, UK

1 Popper, K & Miller, D *Nature* **302**, 687 (1983), **310**, 434 (1984)
2 Levi, I *Nature* **310**, 433 (1984)
3 Jeffrey, R C *Nature* **310**, 433 (1984)
4 Good, I J *Nature* **310**, 434 (1984)

POPPER AND MILLER REPLY—In 1878, Peirce drew a sharp distinction between "*explicative, analytic,* or *deductive*" and "*amplifiative, synthetic,* or (loosely speaking) *inductive*" reasoning. He characterized the latter as reasoning in which "the facts summed up in the conclusion are not among those stated in the premisses". This was the background to our brief letters (refs 1, 2 in Wise and Landsberg's letter). We identified the amplifiative part, relative to any evidence e, of any hypothesis h, with the conditional proposition $h \leftarrow e$; and we proved quite generally that if $p(h, e) \neq 1 \neq p(e)$, then

$$s(h \leftarrow e, e) = -ct(h, e)ct(e) < 0 \quad (1)$$

where

$$s(x, y) = p(x, y) - p(x)$$

and

$$ct(x, y) = 1 - p(x, y).$$

Accordingly, the ("amplifiative") part of the hypothesis h that goes beyond the evidence e is always counter-supported by the evidence. This was our thesis. (The other part, which we wrote $h \vee e$, is of course a deductive consequence of e, and is deductively supported by e.) Both the measures of support and of content are additive:

$$s(h, z) = s(h \vee e, z) + s(h \leftarrow e, z) \quad (2)$$

$$ct(h, z) = ct(h \vee e, z) + ct(h \leftarrow e, z) \quad (3)$$

(Equations (2) and (3) are valid for all h, e and z, and thus for $z = e$.) Wise & Landsberg note that there are other ways of writing $s(h, e)$ in the form $\ulcorner \pm s(x, e) + \pm s(y, e) \urcorner$; for example

$$s(h, e) = -s(\bar{h} \vee e, e) + -s(\bar{h} \leftarrow e, e) \quad (4)$$

This equation (4) is a simplification of their formula (2). It can be obtained by substituting $\bar{h}$ for h in our (2) above, and multiplying by -1. Obviously, neither $\bar{h} \vee e$ nor $\bar{h} \leftarrow e$ is part of the content of h. Thus we fail to see how our (4)—that is to say, their (2)—can possibly challenge our thesis, or have any bearing whatsoever on it.

Gastric cancer and salivary nitrate and nitrite

SIR — Forman *et al.*[1] reported lower salivary and nitrite levels in healthy subjects from areas of Great Britain with high gastric cancer incidences, compared with subjects from areas of that country with low incidences of this cancer. These unexpected findings were used to argue against the theory[2,3] that the intra-gastric formation of carcinogenic *N*-nitroso compounds (NOC) from nitrite is involved in the aetiology of gastric cancer. Although this theory remains controversial, I have three objections to the suggestion that the results presented by Forman *et al.* disprove the NOC theory.

(1) A lower nitrate intake was reported[1] in the diet of the high-risk subjects, which accounted for their lower levels of salivary nitrate and nitrite. Since most dietary nitrate (76-89% in this study) arises from vegetables, which supply much of our dietary vitamin C, the high-risk subjects

probably ingested less vitamin C than did those from the low-risk areas. Hence the high-risk subjects could have produced more intra-gastric NOC, despite their lower salivary nitrite levels. The relevant property of each vegetable may be the ratio of vitamin C to nitrate content, and not nitrate content alone[4]. The intake of fresh fruits and vegetables is negatively correlated with gastric cancer incidence[2], suggesting that the critical components here are vitamin C and other nitrosation inhibitors.

(2) The same argument applies to socio-economic class, since the "lower" classes have relatively high incidences of gastric cancer[2] and showed lower salivary nitrate and nitrite levels in the reported study[1], but would be expected to consume less vitamin C in fresh fruits and vegetables.

(3) Forman *et al.* reported lower salivary nitrate and nitrite levels in cigarette smokers than in nonsmokers, as did Ladd *et al.*[5]. Both groups attributed this finding to the high level of salivary thiocyanate in smokers. Smokers have raised incidences of various types of cancer, possibly including gastric cancer[1,2]. Some of these cancers are likely to be induced by NOC in tobacco smoke or produced *in vivo* from smoke constituents[6]. These findings in smokers do not, as suggested[1], discredit the NOC theory because thiocyanate is a powerful catalyst of nitrosation[7] and we might therefore expect smokers to show an increased NOC formation, despite their lower levels of salivary nitrite.

In 1981 Ohshima and Bartsch[8] developed a method of measuring the potential for *in vivo* (probably intragastric) nitrosation. They fed nitrate and the amino acid L-proline to volunteers, and detected microgram amounts of the noncarcinogenic nitrosamine, *N*-nitrosoproline, in the 24-hour urines. Using this test, Ladd *et al.*[5] reported that smokers given nitrate and proline indeed had a greater urinary excretion of nitrosoproline than did non-smokers, despite the smokers' lower salivary nitrate and nitrite levels. Similar nitrosoproline data were reported by Hoffmann and Brunnemann[9]. These findings prove that salivary nitrite levels cannot be used to predict the potential for intragastric NOC formation.

In conclusion, it is interesting that salivary nitrate and nitrite levels follow the opposite trend to that expected from the NOC theory. However, *in vivo* nitrosoproline formation[5,8,9] offers a more valid test for potential *in vivo* NOC formation and the exposure to nitrosation inhibitors, such as vitamin C, and catalysts, such as thiocyanate, must be taken into account. (The role of vitamin C was addressed in ref. 1, but with a different emphasis.)

FORMAN *ET AL.* REPLY — In our study, we did not set out to disprove the theory "that the intragastric formulation of carcinogenic *N*-nitroso compounds (NOC) from nitrite is involved in the aetiology of gastric cancer", but rather to test the hypothesis "that an increase in nitrate exposure may represent an increased cancer risk". We agree with Mirvish that the negative relationship we observed between salivary nitrates and nitrites and gastric cancer could be due to an association between the consumption of vitamin C (or other protective factors in vegetables) and the consumption of nitrates and suggested this in our paper. We agree, too, that the increased secretion of thiocyanates by smokers might account for the increased risk of gastric cancer in cigarette smokers that has been reported in several series. We clearly stated in the paper that our results do no more than "weigh against the idea that environmental nitrates and nitrites play a major role in determining the risk of gastric cancer in Britain" and we emphasised that this should not "be taken to imply that nitrate-related *N*-nitroso compound carcinogenesis has no role in the development of gastric tumours". Our conclusion is supported by the recently published results of Beresford showing that in Britain the risk of gastric cancer is negatively correlated with the nitrate content of the water supply in over 200 urban areas (*Int. J. Epidemiol.* **14**, 57-63; 1985) and by our observations on men producing nitrate fertilizers, who are certainly exposed to unusually large amounts of nitrates, and whose mortality from gastric cancer is almost identical with that experienced by other men in the same part of Britain (our work, in preparation).

It is clear that whatever the role of NOC in human carcinogenesis may be, direct exposure to nitrate *per se*, does not appear to be a critical risk factor in the United Kingdom. We agree that *in vivo* nitrosoproline formation has the potential for a useful test of *in vivo* NOC formation and are ourselves conducting more research in this area.

Spreading rate of an Arctic ice shelf

SIR — In connection with problems of creep and *à propos* the work of Doake and Wolff[1] on the flow law for polar ice sheets, Weertman[2] calls for measurements of the spreading rate of the Ward Hunt Ice Shelf, Ellesmere Island, Arctic Canada. This was an oversight on Weertman's part because, when I was in charge of field operations in the area for the Canadian Defence Research Board, I arranged for such measurements to be made under the supervision of Dr G. Konecny, then of the Univeristy of New Brunswick.

The work was performed with a geodimeter during the field seasons 1964, 1965 and 1968, and the data were analysed in detail by Dorrer[3], who derived a value of 1.17×10^{-4} yr^{-1} for the spreading rate where the mean thickness of the ice shelf was 38 m. Weertman now agrees that both Doake and Wolff's ice shelf data and Dorrer's ice shelf data appear to go against a linear creep law.

Powers of ten *correctly* expressed

SIR — Claude Liébecq (*Nature* **314**, 586; 1985) thinks that an ordinate with figures ranging from 0 to 10 and labelled "Radioactivity (c.p.m. $\times 10^{-3}$)" is labelled incorrectly if, for example, one of the values included is 5,000 c.p.m. It is indeed labelled incorrectly if one thinks of the label as an equation in the form "Radioactivity = 5,000 × c.p.m.". But if, with more logic, one thinks of the words written vertically simply as a label describing what the figures are, then "c.p.m. $\times 10^{-3}$" is correct.

In other words, instead of substituting "5" for the "c.p.m." in the expression "c.p.m. $\times 10^{-3}$" (giving the incorrect "Radioactivity = 5×10^{-3}"), one may understand the ordinate to mean "c.p.m. $\times 10^{-3} = 5$", or "c.p.m. $= 5 \times 10^{3}$".

Clearly, the meaning of the ordinate can be read in different ways, and there ought to be agreement on how to read it. I suggest that the words on the ordinate be viewed, as I believe they already are by a majority of my colleagues, simply as a label describing the figures, and not as part of an equation.

Prospects for an ageing population

from Jacob A. Brody

The ageing populations of industrialized societies are more likely to be encumbered by increased morbidity than some optimistic arguments would suggest.

OLIVER Wendall Holms, American physician-poet, likened human ageing to the obsolescence of a "one-hoss shay".

Two metaphors of ageing:

Have you heard of the wonderful one-hoss shay,
That was built in such a logical way
It ran a hundred years to a day,
And then, of a sudden, it.

You see, of course, if you're not a dunce,
How it went to pieces all at once,
All at once, and nothing first,
Just as bubbles do when they burst

End of the wonderful one-hoss shay.
Logic is logic. That's all I say

In stark contrast are W.B. Yeats' lines in the poem "Sailing to Byzantium":

Consume my heart away; sick with desire
And fastened to a dying animal
It knows not what it is

HUMAN lifespan, or survival potential[1], cannot be less than 110 to 115 years; some humans have survived that long. It is even possible that lifespan will be found to exceed this estimate, perhaps by a considerable amount. Life expectancy, on the other hand, the average of the years of life from birth or other stated age, is a projection based on accumulated data[1]. In the United States, life expectancy is now 71 years for males and 78.3 years for females, an average of about 74 years for both sexes[2]. This discrepancy between life expectancy and lifespan, about 40 years, is a matter of legitimate concern.

What are the prospects for the years ahead? In an influential article published in 1980, J.F. Fries[3] postulated that the mean age of death, or the average potential life expectancy, would eventually become 85 years, with 95 per cent of deaths occurring between ages 77 and 93. This consideration is not easily reconciled with current life expectancy in the United States, which at age 85 is 6.3 years and at age 91 remains 4 years[4]. Most other authors[5-7] and the Social Security Administration[8] have therefore concluded that average life expectancy will increase to more than 85 years within a century. Yet, Fries describes his conclusions as: "a set of predictions that contradict the conventional anticipation of an ever older, ever more feeble, and ever more expensive-to-care-for populace These predictions suggest that the number of very old persons will not increase, that the average period of diminished physical vigour will decrease, that chronic disease will occupy a smaller proportion of the typical lifespan, and that the need for medical care in later life will decrease." This conclusion offers a comfortable solution as a daunting problem to health policymakers and fiscal planners, but may engender a dangerous optimism. Here I present a less simplified account of the balance between mortality and morbidity in this century and the next.

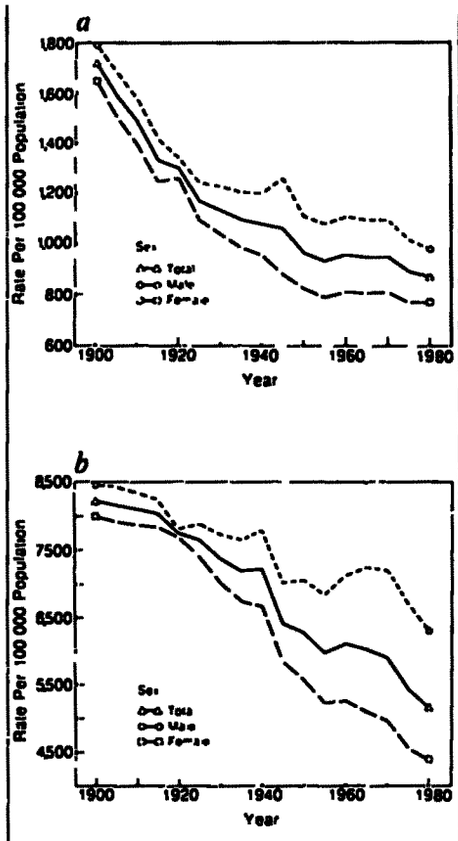

Fig. 1 *a*, Mortality rate for years 1900-79, by sex (all ages) *b*, Mortality rates for years 1900-79, by sex (ages 65 and over). Source National Center for Health Statistics, various volumes of *Vital Statistics of the United States*.

Mortality reduction

In 1900, only a quarter of the US population survived to the age of 65. Now almost 70 per cent achieve this age, and the proportion of those aged 80 and over is 30 per cent and increasing[9]. Within a very few years, about half the population will live more than 80 years. But the pattern of reduction in mortality has not been smooth over time, or easily explicable. Figure 1*a* shows that the mortality rate per 100,000 for all ages fell from 1,720 to 868 between 1900 and 1980. Half of the remarkable decrease observed this century had been complete by about 1920. Neither physicians nor social planners were prime movers in the period during which the greatest mortality reduction occurred — improved living environments and better sanitation were the major factors in the decline.

Among those aged 65 and over, mortality had declined by barely 5 per cent by 1920 (Fig. 1*b*), an indication that the older population was resistant to whatever factors caused the conservation of life in the general population. By about 1945, however, half of the decline in mortality among those 65 and over in this century had been completed. The era between 1920 and 1945 was an historic one in the United States — including the Second World War, the Depression, the beginning of Social Security and Prohibition. While any number of influences may have caused the decline of mortality by 1945, specific medical or social interventions are unlikely to have been major contributors.

During the period from 1945 to about 1968, when it may be thought that medical and social factors should have been reducing mortality rates for the entire population, the overall rate was generally unchanged, with an actual increase in mortality among those aged 65 and over. This seems to have reassured policymakers and planners and, in a sense, lulled them into the false assumption that the maximum potential for human life expectancy had been achieved[10]. Yet since about 1968, mortality rates have persistently declined with only minor perturbations (Fig. 1). Declining mortality among those 65 and over has been remarkable, causing a disproportionate accumulation of the oldest and most vulnerable sector of the population.

Can this recent trend be ascribed to medical and social interventions? Undoubtedly they have had some impact, particularly by the application of medical means for the reduction of blood pressure and, in the United States, by the improvement of medical care through Medicare and other health-insurance programmes. There has also been reduction in smoking and some improvements in diet and exercise; while the scientific demonstration of the benefits of diet and exercise is fragile, presumably some good comes from an intelligent and moderate approach to eating and activity. But careful analysis of the data about the powerful determinants of human health and longevity, such as the avoidance of smoking and the use of antihypertensive agents, reveals that neither of these influences can explain either the extent or the timing of the decline of mortality in the elderly since 1968[11]. The major impact of blood-pressure control and

reduced smoking has yet to be fully realized, so there are likely to be even greater gains in life expectancy in future years.

Yet, actuarial arguments such as those used by Fries, as well as the projections of the Social Security Administration, serve as the cornerstone of major policy decisions. My own discomfort with this approach stems from my conviction that we do not have satisfactory answers to the questions of what has brought about this dramatic mortality decline of the last few decades, and of what still sustains it.

In the past 150 years, there have been major shifts in the causes of mortality and morbidity which have profoundly influenced attitudes towards public health and policy. Important diseases have disappeared or diminished, but for the most part we do not know why. Many of the greatest medical triumphs are not easily attributable to our own constructive action[12].

Tuberculosis was the chief cause of death in the United States and northern Europe at the turn of the century, but even by then there had been a very rapid decline in mortality from tuberculosis since 1856 (Fig. 2). The tuberculosis bacillus was first identified in 1882, and specific therapies for tuberculosis were introduced only in the late 1940s These developments were, therefore, of small importance in the decline of the disease. Similarly, for reasons not understood, deaths from scarlet fever declined precipitously from 1870 to 1900, although the sulpha-drugs and penicillin were not in common use until the Second World War. Moreover, surprising shifts in causes of death are not confined to diseases of infectious aetiology The rate of mortality from accidents among the elderly has declined rapidly since 1950[13] as have deaths from stroke and stomach cancer[14], while conversion hysteria, one of Freud's most frequent diagnoses, seems to have vanished.

One phenomenon that has, however, had a great impact on health trends and thus on current attitudes is the remarkable decline since the late 1960s in mortality from ischaemic heart disease[15] which, in my opinion, created a false sense of optimism about the extent to which we are in control of our survival[11,16]. Heart attacks appear to be a twentieth-century medical chimaera. There is no real mention of the classical heart attack or myocardial infarction before 1900: the generally accepted first reference is Herrick's in 1912[17]. It is possible but unlikely that the medical profession missed the diagnosis of myocardial infarction or systematically misclassified it; the extraordinarily dramatic nature of a heart attack, with its crushing chest pain and pain radiating down the left arm make it a notable event Surely our authors and playwrights would have described an event so frequent and dramatic as we now witness, but there are no good descriptions of heart attacks in a literature rich with accounts of gout, epilepsy, apoplexy and

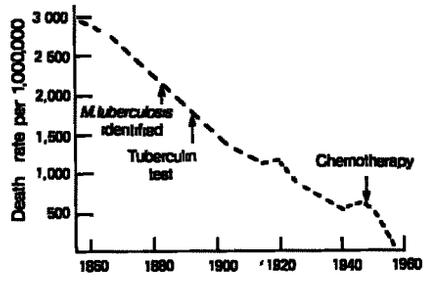

Fig. 2 Respiratory tuberculosis in the total population Source. Mean death rates from various diseases, England and Wales, 1860-1960. From ref 45

tuberculosis. It is probable that acute myocardial infarction was projected into prominence by circumstances arising early in this century, probably associated with the introduction of cigarette smoking and different types and amounts of fat in the diet. Mortality from heart attacks has declined rapidly in the United States since 1968, but this decline has not occurred throughout the world. In Sweden[18] and Japan[19] there has been no comparable decline, although life expectancy is greater than in the United States.

Mortality from heart attacks increased during a period when general mortality was declining. Cause-specific mortality shifted early this century from infectious diseases to chronic diseases and now half of all deaths are caused by heart disease, a large fraction of which result from acute myocardial infarction. After the Second World War, the decline in mortality ended, and was followed by a plateau and then a rise (Fig. 1). This may have resulted from an abatement of the forces that had reduced mortality early in the century, and an increase of mortality from heart attacks. Acute myocardial infarction, however, appears to have been a chance phenomenon which, while causing serious damage, depended for its maintenance and increase on tenuous and complex factors, certainly including smoking and diet The rapid decline in deaths from acute myocardial infarction began in the late 1960s and it is likely that United States age-specific mortality rates since 1900 would have shown a smooth steady decline over the entire years had it not been for the shifting pattern of mortality from this cause.

So this underlying momentum for life extension seems not to be determined by a decline in cause-specific mortality, but rather to be part of a pattern in which the potential lifespan is ever more closely attained But concomitantly with increased longevity, there has also been a steady increase in average height of successive generations for more than a century Gains in growth probably result from the reduction in infectious diseases and from better nutrition in the formative years. There is evidence, in some populations, that growth may now have reached a plateau[20].

It is hard not to think that there must be a relationhsip between these phenomena. Each generation is more closely approaching the human growth potential and this process is apparently reflected in successively-improved trajectories for survival. Therefore, studying the past history of disease and mortality data can yield only fragile guesses about human survival.

The problem is further compounded because 17 per cent of current deaths in the United States occur in people born before 1900, before the era of complete and accurate vital statistics, so we do not have complete data from even a single cohort upon which to base projections. But it is a fact that older people are living longer[9]. Moreover, no other species has ever had our potential for controlling our environment, so that the limits of life expectancy or maximum attainable longevity are not known. There are no empirical data of great value to instruct us on the limits of these unprecedented happenings.

Disability

Life expectancy is increasing at a remarkable rate among the elderly, but are their lives more satisfactory? Scientific documentation of quality of life and life satisfaction is elusive. Present data indicate a modest gain in healthy years lived and a far greater increase in years of compromised physical, mental and social function[2,21-24]. The net increase in survival translates into more years of ill health.

Logically, greater longevity should be associated with increased years of good health, but critical studies are insufficient. Limited evidence is accumulating in current studies of successive aged cohorts. But there are no data suggesting an age-specific decline in deafness, blindness, hip fracture, osteoarthritis and Alzheimer's disease and related disorders[9].

We lack methods to measure the prevalence of good or compromised health. A promising measurement of health in terms other than of disease and death[27] is "active life expectancy", the endpoint being the loss of independence in daily life. This study documented a substantial decline in active life expectancy between age 65 and 84. Men were shown to die shortly after losing independence, while women lived on with diminishing functional abilities suggesting that, in the future, as male patterns more closely resemble those of females, the number of person-years lived after active life expectancy will further increase. Currently, limitations of activity due to chronic health conditions, in the age groups 65 to 74 years, 75 to 84 years, and 85 years and older are 41 per cent, 51 per cent, and 60 per cent, respectively[28] Annual rates of admission to short-stay hospitals per 1,000 population for these age groups are 299, 451, and 507, and the rates of admission to nursing homes per 1,000, for the same age groups, are 15, 68, and 216 If populations were appropriately studied over time, a pattern of increased active life expectancy might emerge.

Time/trend analysis of health status,

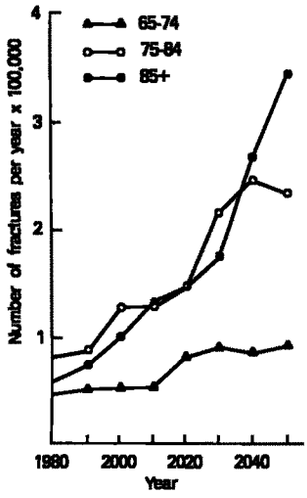

Fig. 3 Projected number of hip fractures annually in the United States by age 1980-2050 Source. NCHS and US Bureau of Census projections.

however, is unreliable. Colvez and Blanchet[29] found a disturbing rise in morbidity and disability since 1957, as did a recent Veterans Administration study[30]. Wilson[31], of the National Center for Health Statistics, commenting on the Colvez and Blanchet report, questions the ability "of health statistics to reflect what might really be happening to health status." He offers plausible explanations for the observed increases in morbidity and disability including artificially high results caused by increased sensitivity of the screening instrument, to a change in attitude towards self-reporting as a result of more liberal retirement benefits for health reasons and improved survival of the chronically ill (implying that the increase of morbidity is real). All this merely emphasizes that there are not sufficient data to reach conclusions about whether people are indeed enjoying better health. Increased public health awareness further confounds interpretation of trend analysis. For instance, as education about hypertension increased in the United States, more people had blood pressure determinations which are a key item in a health-status questionnaire, so that the rate of reported hypertension has increased[29,30].

Longitudinal studies, in which subjects are regularly examined over time, avoid some of the obvious weaknesses of the sequential and cross-sectional surveys but are few in number and, because of the cost and logistical problems, follow only relatively small cohorts. Yet intelligent health policy rests on such research data. Nobody seriously doubts that the disease burden increases with age. It is essential, however, to monitor morbidity, disability and even the quality of life to determine the trends of health as life expectancy increases

Population

The dangers of misinterpreting data are matched by those of presuming knowledge that does not exist. The combination of increasing life expectancy and maturation of the "baby-boom" population will produce extraordinary increases in the numbers of older people in the United States. Within about 40 years (by 2025), the population 65 and over will rise from 11.3 to 20 per cent of the total and will comprise about 60 million individuals. By 2050, the population 85 and over will have risen from about 2 million to more than 16 million[3]. In 10 years, more than half of the people now aged 65 and over will be aged 75 and over. When we now lament that our medical and social systems cannot at present provide for those 65 and over, we forget that it is after age 75 that health problems increase sharply[32]. A concerned government should focus on the realities of the future, not be seduced by fragile notions that the numbers of very old people will not increase, that impairment of physical vigour will decrease and that the result will be the need for less medical care in later life[3].

Three specific examples illustrate physical, mental, and social realities that will occur in the United States unless miraculous advances in science and health management develop in the very near future. In 1980 there were approximately 200,000 people with hip fractures whose median age was 79. Census projections indicate that by the year 2000, before the ageing of the "baby-boom" population, the number will have risen to 330,600 and, by 2050, to more than 650,000, including 340,000 over age 85 (Fig. 3).

In 1980 there were more than 2,000,000 people with Alzheimer's disease and related disorders whose mean age was about 80 years. By the year 2000 the number will rise to 3,800,000 and by 2050 there will be more than 8,500,000, of whom almost 5,000,000 will be age 85 and over (Fig. 4).

There are now about 1.1 million people age 65 and over in nursing homes whose median age is about 80. By the year 2000, the number will rise to 2,200,000 and in 2050 a conservative estimate projects a total of 5,400,000.

Prospects

Unlike the "one-hoss shay", the human body outlives its joints, its cognitive and memory capacities, its vision, its hearing and the many other substrates of disability While concern is limitless, there is at present no accepted scientific prospect that the net increase in healthy years will exceed the increase of years of dysfunction We are, however, far short of reaching the potential of better health and quality of life in later years. Two vehicles offer promise: health promotion through the improvement of personal health practices throughout life, and major research efforts to understand and postpone the ageing processes that inexorably move the elderly into an increasingly morbid and disabled state.

The value of health promotion, involving people in self-care and in achieving wholesome lifestyles is obvious, but a crisis of credibility is emerging in the pursuit of

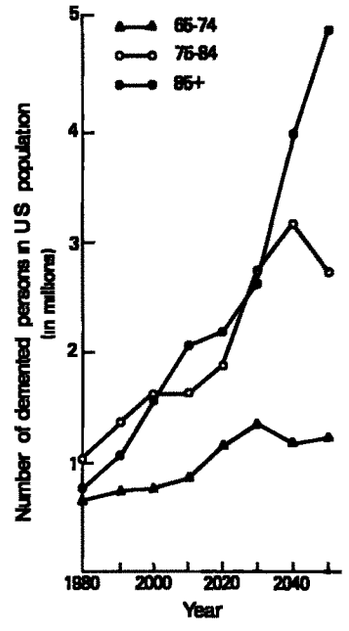

Fig. 4 Projected number of demented persons in the United States by age: 1980-2050. Source, NTA prevalence estimates and US Bureau of Census projections

this goal. One hazard is overstating knowledge when scientific evidence is weak or lacking. In the face of the growing numbers of old and very old people, we must admit that we do not know causes of, and cannot prevent, most chronic diseases[33]; only a fraction of the cancers, heart diseases, strokes, neurological diseases and arthritides are understood, and we know virtually nothing about the causes and prevention of the senile dementias that afflict 20 per cent of people 80 years of age and older[34].

Nobody doubts that smoking and excessive drinking are harmful. Data substantiating the importance of effective treatment of high blood pressure are robust, and at least one study has shown that lowering cholesterol levels is beneficial[35]. Data relating to exercise, weight control, special diets and salt restriction in the absence of hypertension are much less persuasive. Nor do we know how great would be the reduction in morbidity and disability if we produced a population of paragons. Indeed, with almost 70 per cent of the US population now surviving their 65th year, data of Branch and Jette[36] indicate almost no association between most of the commonly advocated personal health practices and mortality among the elderly. To maintain our credibility, we have an obligation to admit our ignorance of causation and our propensity to engender guilt and anxiety among the elderly in areas in which the benefits of specific preventive techniques are not scientifically documented[16].

Another area of health promotion that requires rethinking is behaviour modification through health education. Although considerable benefits may be achieved by altering lifestyles, the results so far have been uneven and equivocal[37,38]. There may

be a systematic obstacle in health education related to an individual's educational level. The classic US study by Kitagawa and Hauser shows a distinct survival advantage among the better educated[39] and is supported in the current literature[40,41]. A recent British investigation reported similar findings[42], noteworthy because medical services have been available free in Britain since 1948.

Education (and its concomitants, all of which are harder to measure) has a powerful effect on life expectancy. People with minimal education may not be reached by the available means of health education. Elimination of smoking, moderation of alcohol consumption, diet control and other attemps at modification of lifestyle will have by-passed this less well educated group, which continues to inflict needless self-harm. We need a new direction in behaviour modification through health education, with the primary target being those with fewer years of education. We may be wasting much of our resources by failing to modify clearly harmful health practices in this inaccessible high-risk subpopulation.

In research, it is important that we should place emphasis on conditions that become more prevalent with ageing, such as blindness, deafness, Alzheimer's disease, acute and chronic heart disease, diabetes, and hip fracture, and that we should develop mechanisms to postpone them. This approach has increasing value as life expectancy reaches or passes 85 years, as illustrated with hip fractures and the associated osteoporotic process. Our data[43] indicate that hip fractures start to rise in frequency in the early forties and thereafter increase exponentially, doubling every 6 years (Fig. 5). If research on bone metabolism could provide a mechanism for delaying osteoporosis so as uniformly to postpone the onset of the exponential rise in hip fracture, the incidence of this condition would be reduced by 50 per cent[44]. Research directed at the precursors of disability is the most effective tool to prevent chronic disease and attendant disabilities.

The most urgent need is of an understanding of human natural history beyond age 65, using the emerging data on elderly populations. The increase in life expectancy among the elderly is unprecedented in human history and probably relates to longer survival trajectories for successive cohorts rather than to specific disease control. The causes of the systematic alteration between 1900, when 25 per cent of the population survived their 65th year, and 1980, when almost 70 per cent did so, demands explanation.

Meanwhile, in our state of ignorance, making assumptions with major policy implications is dangerous. When we speculate in good faith, but on a basis of soft data and with projections that human history has already denied, we run the risk of ignoring Hippocrates' basic admonition that

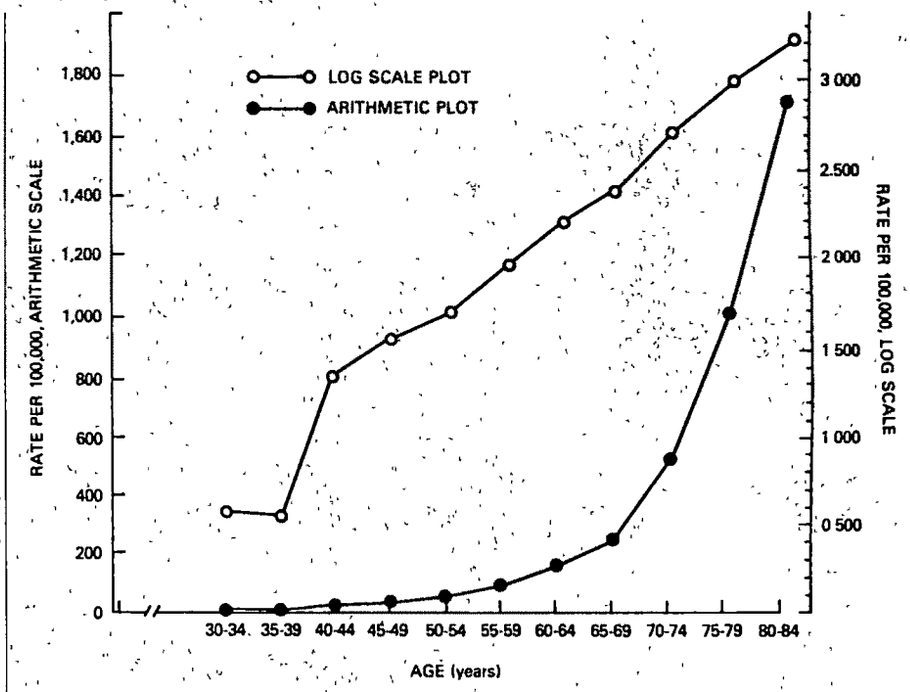

Fig. 5 Age-specific hip fracture incidence among white women. Source: National Hospital Discharge Survey 1975 to 1979.

"the physician must be able to tell the antecedents, know the present and foretell the future — must meditate these things, and have two special objects in view with regard to diseases, namely, to do good or to do no harm."

Parts of this paper were presented at a University of Connecticut Symposium and will appear in the *Philosophy and Medicine Series* by D. Reidel Publishing Company. □

Mass distribution in the galactic centre

M. K. Crawford, R. Genzel, A. I. Harris, D. T. Jaffe, J. H. Lacy*, J. B. Lugten, E. Serabyn & C. H. Townes

Department of Physics, University of California, Berkeley, California 94720, USA

New infrared and submillimetre spectroscopic measurements of the gas dynamics in the central 10 pc of our Galaxy make a convincing case that the mass distribution at the centre of the Galaxy is more concentrated than a spherical isothermal stellar cluster. The measurements fit a point mass of $\sim 4 \times 10^6$ $M_\odot$ but are also consistent with a cluster where stellar density decreases with radius (R) at least as fast as $R^{-2.7}$, or a combination of a point mass and a stellar cluster. The dynamical information combined with previous 2-μm observations favour a large point mass, which is presumably a massive black hole.

THE possible existence of massive black holes at the nuclei of galaxies is an important long-standing question. The lack of spatial resolution has limited the work in external galaxies, and the observational difficulty in establishing a reliable answer to this question even in our own Galaxy is quite formidable. The centre of our Galaxy is obscured visibly, and material along the line-of-sight to the centre hampers radio investigations. Here we discuss new information on the gas dynamics in the galactic centre, available from spectroscopy in the infrared and submillimetre regions. This new information allows a determination of the rotational velocity of the interstellar material between ~0.5 and 10 pc from the centre and gives some discrimination between possible mass distributions. The observations entering into the analysis comprise a large body of data which adds considerable detail to our knowledge of the velocity and mass distribution in the central 10 pc of our Galaxy. These data will be presented and discussed in detail elsewhere[1-4]. Here, we provide a brief summary of our present understanding of the galactic centre based on these new results. Distance to the galactic centre is assumed to be 10 kpc.

Previous observations of inner 10 pc

Figure 1 indicates the distribution of interstellar gas and dust in the inner 10 pc of our Galaxy[2,5]. High-resolution Very Large Array (VLA) maps[5-7] show that much of the free-free radio continuum emission from Sgr A West, the radio source in the galactic centre, is distributed in large-scale filamentary structures which may be spiralling into or out of the galactic centre, or orbiting around it[5-7]. There is also an unusual radio point source (Fig. 1, refs 8, 9), whose position almost exactly coincides with the infrared source IRS16 which is very close to if not at the dynamical centre of the Galaxy[10,11]. Spectroscopic measurements of the ionized gas show hydrogen and helium with a velocity range of 1,500 km s^{-1} within 3 arc s of IRS16 (refs 12, 13). At 10–20 arc s from IRS16, measurements of singly ionized neon[14] and of hydrogen recombination lines[15] indicate substantially lower velocities. A statistical analysis based on the velocity dispersion of Ne II-emitting clouds as a function of distance from IRS16 implies that a point mass of $\sim 3 \times 10^6 M_\odot$ combined with an isothermal stellar cluster (density $\propto R^{-2}$, where R is the radius) is a more probable mass distribution for the centre than a R^{-2} stellar cluster, but the level of significance of this result is not high[14].

Far-infrared continuum observations indicate that a ring or disk of neutral dust and gas surrounds the centre from a radius of ~2 pc outward and that inside this region dust and gas is of substantially lower average density[16]. These data (Fig. 1) imply that the neutral dust disk is oriented approximately in the plane of the Galaxy such that two lobes representing the inner edge of this disk appear on either side of the ionized region, apparently encompassing it. Far-infrared measurements of the O I fine structure line at 63 μm show that this disk rotates around the galactic centre, with an axis approximately that of general galactic rotation[17]. Emission from H_2 molecules at 2 μm indicates that the disk contains hot (~2,000 K) gas, which is probably shock-excited[18]). Radio observations of the 21-cm H line and the 1-0 rotational line of CO show that cooler material in the disk extends to ≥6 pc from the centre[19].

New data on galactic centre

New spectroscopic results provide a much more detailed dynamic picture of the ionized gas features by a more complete examination of Doppler shifts of the 12.8-μm Ne II fine-structure line. A much clearer picture of the velocity distribution in the neutral disk out to ~10 pc from the galactic centre comes through mapping of various far-infrared lines, including: (1) fine-structure lines of O° in the ground state (at 63 and 146 μm); (2) the fine-structure line of C^+ at 158 μm; and (3) the $J = 7 \rightarrow 6$ rotational transition of CO at 372 μm. The O I and C II data were taken on the Kuiper Airborne Observatory with a Fabry-Perot spectrometer[2,3], the Ne II line with a Fabry-Perot-grating spectrometer using the IRTF telescope on Mauna Kea, Hawaii[1], and the 7→6 transition of CO with a newly developed heterodyne spectrometer, also at the IRTF[4].

Ionized streamers. New spectra of the Ne II line were taken at 110 different locations with 1.5-6-arc s resolution, principally along the structures in the VLA radio continuum map. The questions of interest were whether the velocities of the filamentary structures are continuous and characteristic of material in systematic motion, and which arms of the various streamers are parts of the same dynamic structures. The results and their interpretation are discussed in detail in ref. 1 (see also ref. 15) and are summarized here.

There are at least two long, coherent streamers of ionized gas. Their velocities and spatial patterns suggest that the gas follows simple orbits around the galactic centre, although there are some deviations from a smooth velocity pattern. As proposed by Lo and Claussen[7], the arc of ionized gas extending from ~30 arc s south of IRS16 to ~15 arc s west of the centre continues further north to ~30 arc s north of the centre (the 'western arc' in Fig. 1) Velocities of the 16 spectral-line centres at approximately equally spaced positions along this ~180° arc vary linearly with declination from −100 to +100 km s^{-1}, with more-or-less random deviations of ~7 km s^{-1} r.m.s. This corresponds to what one expects from the projection of a rotating circle of radius 1.7 pc and rotational velocity of 110 km s^{-1} made up, however, of individual clouds that are not following precisely the same

* Present address: Astronomy Department, University of Texas, Austin, Texas 78712, USA.

orbit. This rotational velocity allows for the observed ellipticity of the arc, which makes the axis of this circle tilted with respect to our line of sight by ~70°. Its extremes lie at the inner edge of the neutral dust and gas disk detected in far-infrared continuum and line radiation[16,17]. As the rotational velocity and projected linear velocity gradient agree with those of the neutral gas at the inner edge of the neutral disk, the western arc is probably the ionized inner surface of the disk. The rather clear-cut circular orbit of the western arc allows a determination of the enclosed mass. If the mass distribution within 1.7 pc is spherical, it contains $4.7 \pm 1 \times 10^6\ M_\odot$. That the circular orbit is ionized and hence visible in Ne II over only about half of its circumference may result from shadowing of a central ionizing source. The shadowing cloud may be, for example, the 'northern arm', which could interrupt ultraviolet radiation west of the centre.

The northern arm (Fig. 1) is another long structure which appears to be a continuous kinematic feature, with velocities varying from 137 km s^{-1} on the northern end to about zero at the declination of the centre. The average change of velocity with distance along this feature is three to four times greater than along the western arc. Hence, this gas feature is closer to the dynamical centre. The velocities in the northern arm reach a maximum of 137 km s^{-1} at a projected distance of 15 arc s (0.75 pc) from IRS16, suggesting that $\sim 4 \times 10^6\ M_\odot$ would have to be enclosed within this radius if this feature were a circular orbit. However, the significant curvature of the velocity curve of the arm indicates that the gas feature is not at constant radius, so that a simple circular orbit analysis is not appropriate. A quantitative examination of the velocities and positions shows that the ionized gas in the northern arm is well described by an eccentric orbit about a point mass, such as a parabola, hyperbola or elongated ellipse. Deviations from such a fit are ~2 km s^{-1} r.m.s., and velocities seem to vary continuously, suggesting an elongation of a single cloud. The inferred orbit passes within 0.5 pc of the central mass of $3.5 \times 10^6\ M_\odot$ located within a few arc s of IRS16. The other model which is of particular interest here is an orbit in an isothermal cluster; such an orbit fitting the measurements of the northern arm still requires a mass of $\sim 3.4 \times 10^6\ M_\odot$ within a radius of 0.5 pc; hence a mass $\sim 11.5 \times 10^6\ M_\odot$ would lie within 1.7 pc, substantially exceeding the mass observed within that radius. It follows that most of the mass contained inside the outer orbit at $R = 1.7$ pc (the western arc) is also within ~0.5 pc of the centre. This mass distribution can result from either a central point mass or a stellar cluster more concentrated than an isothermal cluster, with density falling off steeper than R^{-2}[7].

Neutral material. We have examined the velocities of the neutral material extending from ~30 arc s to several minutes of arc, or ~10 pc from the galactic centre in the far-infrared and submillimetre regions with 30–60-arc s angular resolution. The most recent and improved O I measurements are described in detail elsewhere by R.G. *et al.*[2], the C II results by J.B.L. *et al.*[3] and the CO $J = 7 \rightarrow 6$ results by A.H. *et al.*[4].

The relative intensities of the two O I fine-structure lines and the C II line, as well as the relative intensities of various CO rotational lines[2,4], show that most of the neutral material is in clumps with a hydrogen density near 10^5 cm^{-3} and a gas temperature near 300 K. The total mass of the gas in the neutral disk within ~5 pc is a few times $10^4\ M_\odot$, and <10% of the volume is filled by high-density gas. Maps of intensities of these lines show that the galactic centre gas disk is tilted by ~20° with respect to the galactic plane and may be quite thin (thickness ≤1 pc).

The velocities of all far-infrared and submillimetre emission lines are blueshifted at negative galactic longitudes and redshifted at positive longitudes, with a sharp transition at the centre position. The distributions of integrated line intensities and absolute values of the velocities as a function of longitude offset are very similar on either side of the centre. Rotation is the simplest gas motion fitting this symmetrical distribution and the other observed characteristics of the data. From the orientation of the disk of gas, noted above, and from the velocities measured, the rotation axis must be near that of the general galactic rotation. The velocity at $R = 1.7$ pc determined from the O I and CO measurements is in excellent agreement with the orbital velocity of the western arc. The spectra indicate that velocities decrease with increasing distance from the centre. The velocities at the peaks of the profiles are ±70 km s^{-1} at $R \simeq 2$ pc on respective sides of the centre, and decrease over the next several parsecs to ±50 km s^{-1} at 6 pc and ±27 km s^{-1} at 10 pc. Beyond ~10 pc, the velocity patterns become less clear because the C II lines associated with the dense and warm material close to the centre become weaker and may be contaminated by radiation from other sources along the line of sight. A spectrum of the 1-O CO line at $R = 4.5$ pc (ref. 19) and two Ne II profiles taken at $R = 2.7$ and 5 pc (ref. 20) also support the fall-off of rotational velocity between 2 and 10 pc. The rotation curve is consistent with a 'keplerian ($R^{-1/2}$)' fall-off resulting from orbits around a point mass, and excludes an isothermal cluster.

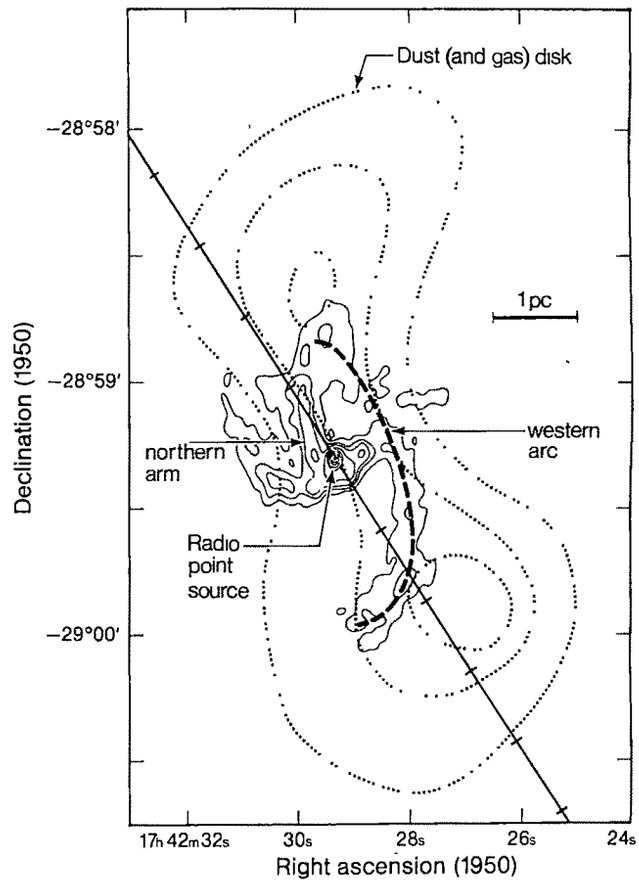

Fig. 1 Sketch of gas in the central 10 pc of the galactic centre. A VLA map of the 2-cm thermal radio continuum emission at a resolution of 2.5 arc s [5] is indicated by the solid contours. Dotted contours give the far-infrared continuum emission from warm dust[2,16]. The galactic plane is marked by diagonal line with ticks every pc. In addition to the filaments marked, the bar is the structure stretching from north-west to south-east ~10 arc s on either side of the radio point source.

In addition to rotation, the neutral disk exhibits some non-systematic motion. For example, lines in many locations are as broad as 100 km s^{-1}, and there is a separate blueshifted cloud ($v = -20$ to -80 km s^{-1} with respect to the local standard of rest) away from the galactic plane north-west of the centre. Nevertheless, for distances greater than 1.7 pc, the measurements give clear evidence of an average rotation. At least some of the irregular motions result from a turbulent velocity dispersion of the gas clumps. In the most central region, O I and CO lines show still larger widths, corresponding to velocities detec-

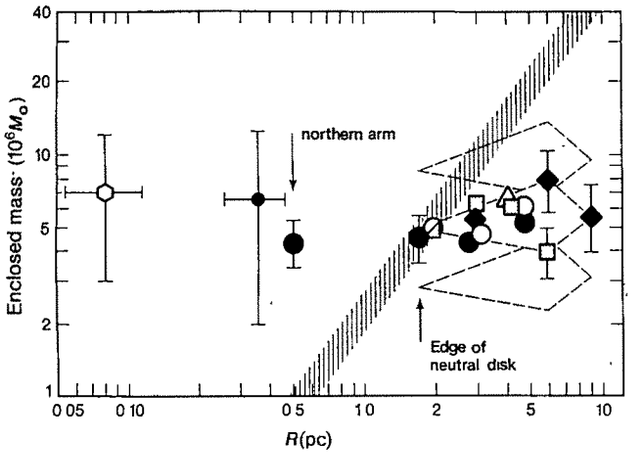

Fig. 2 Enclosed mass as a function of radius from IRS16 The mass distribution is derived from several measurements of the kinematics of neutral and ionized gas discussed in the text With the exception of the mass enclosed within the northern arm from Serabyn and Lacy's fitting of eccentric orbits, all masses were derived assuming circular orbits: $M_{\odot} = v^2 R/G$. Typical error bars are indicated. Velocities in the neutral disk were corrected for an angle between the rotation axis and line of sight (inclination) of 69°. Rotational velocities of the neutral gas in the disk were derived from the terminal velocities (velocity at half maximum), corrected for a local 'turbulent' velocity dispersion of FWHM 50 km s^{-1}. The large dashed diamonds above and below the measured points show where these data on the neutral gas would be without such a correction for non-circular motions, and where they would be if line centroids rather than edges were taken. Relative positions of the points within the dashed diamonds would be essentially unchanged. He I, 2.1 μm (○); Ne II, 12.8 μm (●); O I, 63 μm (○); C II, 158 μm (◆); CO 7→6, 370 μm (▨), CO 1→0, 0 26 cm (△). The Ne II data are from refs 1, 14, 20; O I data from ref. 2, C II from ref. 3; CO 7→6 from ref. 4; and CO 1→0 from ref. 19. The 2-μm He I data (from ref. 13) indicate that velocities of ±750 km s^{-1} occur in a region within a radius of 1-2 arc s, leading to the cross at $R \sim 0.08$ pc. The shaded diagonal bar indicates the mass distribution of a cluster with $4.7 \times 10^6 M_{\odot}$ within a radius of 1.7 pc and a radial dependence of enclosed mass $R^{1.3}$ (from the 2-μm light distribution; refs 23, 24)

ted earlier for Ne II and indicating that there is neutral material in many of the ionized clumps. Normally, the best estimate of the rotational velocities in an edge-on disk comes from the extreme ('terminal') velocities of the profiles. In the galactic centre, these edges are significantly broadened by the turbulent motions (Δv_{turb} (FWHM) ~ 30-50 km s^{-1}). We correct for this broadening in our estimates of the rotational velocities. As indicated in Fig. 2, if turbulence of this magnitude is instead added to the average rotational velocity to calculate average kinetic energy, the mass contained inside a given radius would be increased for the neutral gas measurements, but the fractional rate of change of mass with distance in this region would not be affected. This general result for the fractional rate of change of mass results from the observed decrease in velocity with distance, which makes it relatively insensitive to details of line widths and turbulence.

Discussion

Figure 2, which shows the mass inside of various radii, gives an overview of the mass distribution in the galactic centre. We have derived the masses from the measured velocities assuming a spherical mass distribution. The maximum influence on the derived rotational velocities of corrections for the noncircular motions in the neutral disk are schematically indicated by large dashed diamonds. We choose the points as placed on Fig. 2, using the corrections stated in the legend, as giving the most likely mass values. For other choices, points within the central dashed diamond would approximately maintain their relative positions but be moved with this diamond to its upper or lower positions, depending on one's choice of corrections. In addition to the estimates for the disk, 'western arc' and 'northern arm', we have also indicated a mass estimate from the velocity dispersion of eight Ne II clouds within 8 arc s of IRS16 (from the earlier work by Lacy *et al.*[14]). The line-of-sight velocity dispersion of the inner Ne II clouds, most of which are located in the 'bar' region, is $\sigma_v = 145 \pm 50$ km s^{-1} (ref. 14). We can estimate a mass from the data in Fig. 2 using the virial theorem (enclosed mass $= 3\sigma_v^2 R/G$; see ref. 14), which assumes the gas velocities represent a steady-state distribution. (G is the gravitational constant.) This estimate is about the same as the mass determined from the highest velocity of these clouds (±260 km s^{-1}) assuming circular motion. Finally, a mass estimate within 1-2 arc s of IRS16 originates from the total width of He I and H I lines measured by Geballe *et al.*[13], with the assumption of circular motion. In contrast to the other measurements discussed above, it is not certain that the innermost Ne II and He I/H I velocities represent circulation or any simple orbits. The Ne II clouds in the bar region may be falling into the centre[7], and the He I/H I motions may result from an expanding wind from IRS16 (ref. 13). Hence, these data should be given less weight in the derivation of the mass distribution.

Taken together, the large body of data shown in Fig. 2, measured with different methods and subject to different uncertainties and systematic effects, make a convincing case that at small radii the apparent mass approaches a constant.

The measurements are consistent with a point mass of $4 \pm 1 \times 10^6 M_{\odot}$, or a combination of a $3\text{-}4 \times 10^6 M_{\odot}$ point mass and a small stellar cluster ($1\text{-}2 \times 10^6 M_{\odot}$ within 2 pc and $5\text{-}10 \times 10^6 M_{\odot}$ within 10 pc). They are also consistent with a stellar cluster and no point source if the stellar density decreases as fast or faster than $R^{-2.7}$, and thus exclude an isothermal (R^{-2}) distribution. Some globular clusters and elliptical galaxies have radial density profiles as steep as $R^{-2.7}$ or steeper[21]. Concentrated globular clusters such as M15, for example, have radial density profiles outside their core radii (~0.01-1 pc) which approximately follow a power law $R^{-\alpha}$ with $2.4 \leq \alpha \leq 2.8$ (ref. 22) Such a gradient is consistent with the present data and the main difference between the present case and globular clusters would then be the higher central density and smaller core radius (~0.01-0.05 pc) of the galactic centre mass distribution.

However, additional information on the stellar distribution in the galactic centre, available from observations of the 2.2-μm stellar surface brightness distribution[23,24], makes it unlikely that such a concentrated stellar cluster dominates the mass in the central 2 pc of the Galaxy. The distribution of 2.2-μm surface brightness drops off with $R^{-0.7}$ between 0.05 and 1.5 pc radius from IRS16 (ref. 24), and with $R^{-0.8}$ between 1 and 30 pc (ref. 23) implying a density approximately proportional to $R^{-1.75}$. There is no sign of a flattening in the inward increase of surface brightness, even at the smallest scales observable (≤0.05 pc; ref. 24). The slope of the 2.2-μm emission line is less steep than that of a cluster in isothermal equilibrium, and certainly not steep enough to explain the spectroscopic velocity measurements. The shape of the 2.2-μm light distribution combined with the dynamical information thus suggests strongly that the stars distributed similar to the 2.2-μm light do not contain the major fraction of the mass within 3 pc. Therefore, if the 2.2-μm light distribution in the centre is a measure of the total mass distribution of stars, the mass concentration at the galactic centre probably results from a central point mass of $\sim 4 \times 10^6 M_{\odot}$, most likely in the form of a single massive black hole. Note that the particular radial distribution observed for the stellar cluster would be a natural consequence of a black hole that is more massive than the stellar cluster out to a given radius. Theoretical calculations show that a steady-state balancing between infall of stars towards such a hole and tidal disruption by the hole gives a stellar density distribution proportional to $R^{-1.75}$, similar to what is observed in the galactic centre[25].

There are several reasons why the evidence for a highly concentrated mass at the galactic centre surrounded by a less

massive stellar cluster could be misleading. For example, the 2-μm light distribution may not reflect the mass distribution of the galactic centre stellar cluster. The stellar mass distribution may be more concentrated towards the centre than indicated by the 2-μm light if the stars emitting at 2 μm do not represent a major fraction of the stellar mass. However, the 2-μm light distribution is believed to measure the distribution of K and M giants and supergiants; these would normally be the more massive members of the cluster and should be more concentrated than the cluster as a whole.

A spheroidal or triaxial cluster would have velocities that decrease with distance from the centre rather than the simpler behaviour associated with spherical clusters. In the central plane, however, where velocity measurements are considered in the present study, although the ionized clouds are asymmetrically arranged, they contain little of the total mass and the distribution of gas around the galactic centre is rather symmetrical in both density and velocity. Hence, any extreme ellipticity in the stellar cluster that would give the observed velocity distribution seems improbable. A mild ellipticity of the mass distribution would not change the results qualitatively, but would only decrease the total amount of calculated mass. In the case of the northern arm, one might wonder whether some broadly distributed gas, providing friction to the orbit of any streamer of gas, can produce the curvature and accelerations observed. Quinn and Sussman[26] have proposed such a distribution of hot gas as an explanation for the morphology of the ionized streamers in the galactic centre. The Ne II observations of the western arc and the northern arm, however, exclude the specific model proposed[1], because the measured velocities are substantially different from those predicted by the model. Any more general friction-induced infall model is only possible if it can explain both the almost undisturbed circular orbit of the western arc and the presence of clouds moving as fast as 260 km s^{-1} (ref. 14) very near the galactic centre.

If a black hole accounts for $4\times10^6\ M_\odot$, the measurements in Fig. 2 allow a stellar cluster mass of only $1\text{–}2\times10^6\ M_\odot$ within $R=2$ pc. The total luminosity of the cluster within this radius, which is deduced by assuming the 2-μm radiation represents a distribution of 4,000 K giant stars, is $\sim4\times10^6\ L_\odot$ (refs 23, 24). Hence, the mass to luminosity ratio of the cluster is $\leq0.5\ M_\odot/L_\odot$, which is much lower than typical for old clusters ($M_\odot/L_\odot\sim$ 1.5:5; ref. 21). It may indicate relatively recent star formation activity or a lack of low mass stars. The total luminosity of the region inside $R=1$ pc deduced from the ionizing flux or the longer-wavelength infrared continuum radiation is $\sim2\times10^7\ L_\odot$ (ref. 16), and hence if all the mass were assumed to be stars, the ratio $M_\odot/L_\odot$ would be very low.

Related observations

The turbulent and non-circular motions of the ionized and neutral gas in the galactic centre are significantly larger than in other dense clouds in the Galaxy or than one would expect in equilibrium. It is likely that this gas has been strongly perturbed within a time as recent as a few orbital periods ($\sim10^5$ yr). This disturbance was possibly produced by material which fell into the galactic centre from an appreciable distance. Estimates from the amount of material present and its clumpy distribution indicate that material should fall into the centre at an average rate of $\sim10^{-4}\text{–}10^{-3}\ M_\odot\ yr^{-1}$ (ref. 14). This average rate should generate substantially more energy flux than is presently seen in the region. However, if there were episodic infall, the present perturbations and possibly also the low density of material within the inner radius of the disk could be the result of a past larger infall and very high resultant energy flux. This would also imply that we are now in a time of relative quiescence.

It has previously been argued that the ultraviolet radiation required to ionize gas in the galactic centre could not come from a single point-source, because a black-body source or one with the characteristics of a stellar atmosphere would not produce enough ultraviolet without being a stronger source of infrared than has been observed[27,28]. Now we find that these arguments are not conclusive. Henry *et al.*[10] have already suggested that much of the radiation could originate from the source IRS16. It does seem possible to fit the amount of ultraviolet radiation required to ionize the Sgr A West H II region and the observed infrared intensity of IRS16 to what would be expected from a radiating atmosphere similar to that of an O-type star of surface temperature ~35,000 K and surface gravity of $\log g=5$ (ref. 1), although a large number of O-type stars would be required. The surface gravity tends to decrease radiation energetic enough to ionize Ar^+ or S^{2+}, fulfilling the observed conditions of very few Ar^{2+} and S^{3+} ions, while at the same time providing enough photons to produce the observed Ne^+. Thus ultraviolet and infrared observations seem to be consistent with production of the ultraviolet excitation in the central few parsecs by a single localized source, such as a black hole.

Conclusions

New infrared and submillimetre measurements of the dynamics and distribution of material around the galactic centre have increased knowledge of the structure and mass distribution of this region. A large amount of data seem to fit a model, involving: (1) an unusual concentration of mass not in the form of ordinary stars, most probably a central black hole of mass $4\pm1\times10^6\ M_\odot$; (2) an ionized cavity of relatively low gas density surrounding the centre and of radius 1.7 pc. This cavity also contains an additional $1\text{–}2\times10^6\ M_\odot$ mass in a stellar cluster; (3) a circulating disk of dense ($\sim10^5$ cm^{-3}), warm (300 K) and clumpy neutral gas between 1.7 and ~10 pc which is ionized along much of its inner edge. Irregular gas velocities indicate strong perturbations of the motions in this region over the past few 10^5 yr.

The observed velocities also fit a stellar cluster with no central point mass if the stellar density distribution decreases at least as fast as R^{-2}[7]. However, the case without a central black hole is excluded if the observed 2-μm light distribution is a fair representation of the mass distribution of the stellar cluster.

Terrestrial xenon isotope constraints on the early history of the Earth

M. Ozima*, F. A. Podosek† & G. Igarashi*

* Geophysical Institute, University of Tokyo, Tokyo 113, Japan
† Department of Earth and Planetary Sciences, Washington University, St Louis, Missouri 63130, USA

Comparison between ^{129}I-radiogenic ^{129}Xe and ^{244}Pu-fissiogenic ^{136}Xe components in terrestrial xenon suggests that the Earth's inner region accreted a few tens of millions of years earlier than the outer region from which the atmosphere evolved. The results also indicate that there has been no substantial mixing of the two regions since the Earth's accretion.

SINCE the discovery of excess ^{129}Xe in meteorites[1], Xe isotopes produced from ^{129}I (half-life $t_{1/2}=17$ Myr) and from ^{244}Pu ($t_{1/2}=82$ Myr) have been a prime source of information on the early history of meteorites. Although there has been considerable work on Xe in meteorites, there is still relatively little Xe isotope data for terrestrial samples: nevertheless, some very interesting results have emerged, notably the confirmation of large excess ^{129}Xe and $^{132-136}Xe$, relative to air Xe, in gas from a CO_2 well in New Mexico[2-5]. There have also been reports of excess ^{129}Xe in some mantle-derived materials, such as mid-ocean ridge basalts (MORB)[6-8], mantle xenoliths[9-11] and diamonds[12]. The existence of excess ^{129}Xe indicates that the source region for the excess ^{129}Xe must have been isolated for almost the whole history of the Earth from the atmosphere and/or the rest of the mantle from which the atmosphere was generated. It has been argued[6,7,13-15] that the isolation of this source must correspond to degassing of the mantle and, therefore, that this degassing, and the major generation of the atmosphere, occurred very early, within a few half-lives of ^{129}I after the formation of the Earth.

We now examine published data on Xe isotope composition in terrestrial samples and discuss their implications for the early history of the Earth. We show that the terrestrial Xe isotope data need not lead to the conclusion that the excess ^{129}Xe requires very early mantle degassing, as generally assumed.

Terrestrial Xe isotope data

From published Xe data, we have constructed three isotope plots for granites, MORBs and upper-mantle derived rocks (mostly mantle xenoliths) (Figs 1-3). The data for New Mexico CO_2-well gas Xe is shown in the plots for granites (Fig. 1). In plotting these correlation diagrams our only selection criterion was to discard those with abnormally large error assignments. For step-heating data, we discarded the lowest temperature fraction, which would probably include large air contamination, and we chose as a representative value, the fraction with the largest amount of Xe. For the New Mexico CO_2-well Xe, we used the latest experimental data[5] (Fig. 1).

Granites (Fig. 1) show a very clear linear correlation which must be due to the addition of ^{238}U-fissiogenic Xe isotopes[16] as granite typically has relatively high concentrations of U. The slopes of the correlation lines (solid lines) in the $^{134}Xe/^{130}Xe$-$^{136}Xe/^{130}Xe$ and $^{132}Xe/^{130}Xe$-$^{136}Xe/^{130}Xe$ diagrams give the ratios of the fission yields $^{134}Y/^{136}Y$ and $^{132}Y/^{136}Y$, respectively, which agree well with the laboratory values of 0.832 ± 0.02 and 0.59 ± 0.017 for spontaneous fission of ^{238}U. Figure 1 also shows the correlation lines (dotted lines) corresponding to ^{244}Pu-fissiogenic Xe, which do not fit the data well. The isotope composition for New Mexico CO_2-well Xe falls on the correlation lines, indicating that the excess ^{132}Xe-^{136}Xe is also due to ^{238}U-fission, as was concluded by Phinney *et al.*[4]. However, the CO_2-well gas Xe has significant excess ^{129}Xe, which is not seen in granites. This excess ^{129}Xe has been confirmed independently[3-5] and its existence seems to be established.

Excess ^{129}Xe may also exist in MORB (Fig. 2) and mantle-derived xenoliths (Fig. 3). In addition, ^{136}Xe and ^{134}Xe appear to show slight excesses relative to air Xe. However, correlations between $^{136}Xe/^{130}Xe$ and $^{134}Xe/^{130}Xe$, $^{132}Xe/^{130}Xe$ are vague and it is not possible to resolve whether the excess $^{132-136}Xe$, if real, is due to ^{238}U-fission or to ^{244}Pu-fission. The only known source for excess ^{129}Xe is the extinct nuclide ^{129}I. The existence of the excess ^{129}Xe indicates that some part of the Earth had incorporated a non-trivial amount of short-lived ^{129}I and has not undergone extensive exchange with the atmosphere, or the source of the atmosphere, since before the decay of ^{129}I was substantially complete. For excess ^{131}Xe-^{136}Xe, both ^{238}U-fission and ^{244}Pu-fission could be responsible. Except for crustal rocks, which are more enriched in U, ^{244}Pu-fissiogenic Xe is likely to be more important than ^{238}U-fissiogenic Xe in the Earth as a whole[17].

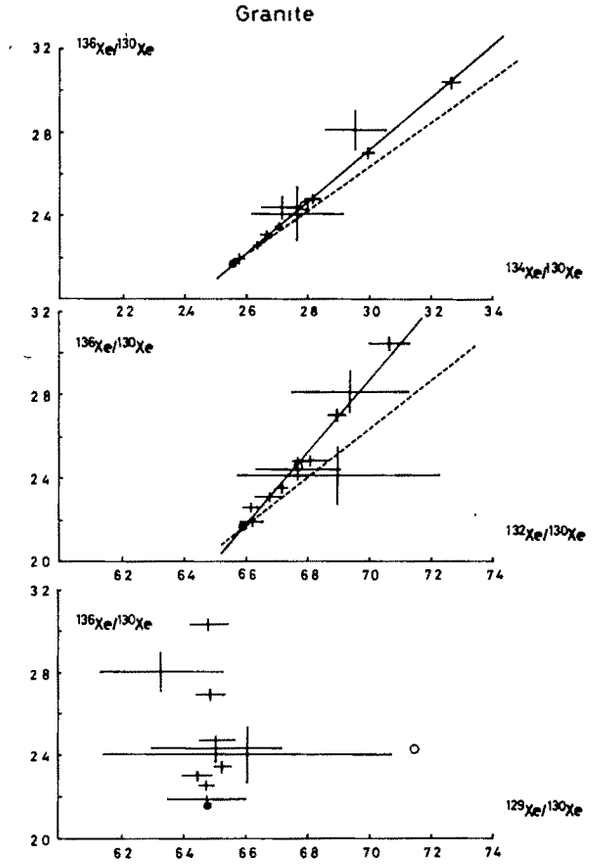

Fig. 1 Three isotope plots for granite samples[16]. Also shown are New Mexico CO_2-well gas Xe (O, data from ref. 5) and air Xe (●). Note that the CO_2-well gas Xe data lie on the correlation lines, which characterize ^{238}U-fissiogenic Xe (solid lines). For comparison, a correlation line for ^{244}Pu-fissiogenic Xe is also shown by a dotted line.

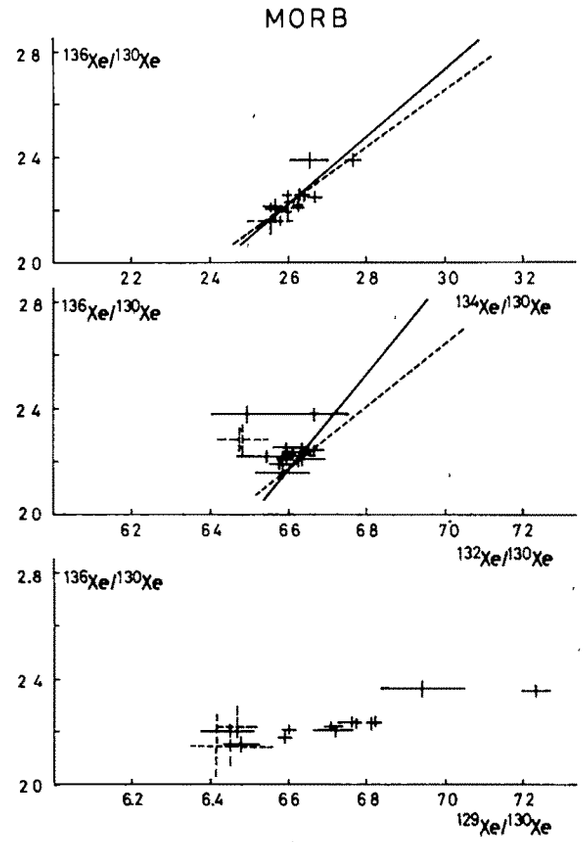

Fig. 2 Three isotope plots for MORB. Solid cross, data from refs 6, 7 Dotted cross, data from ref. 27. Note that neither the ^{244}Pu-fissiogenic nor the ^{238}U-fissiogenic lines fit the data

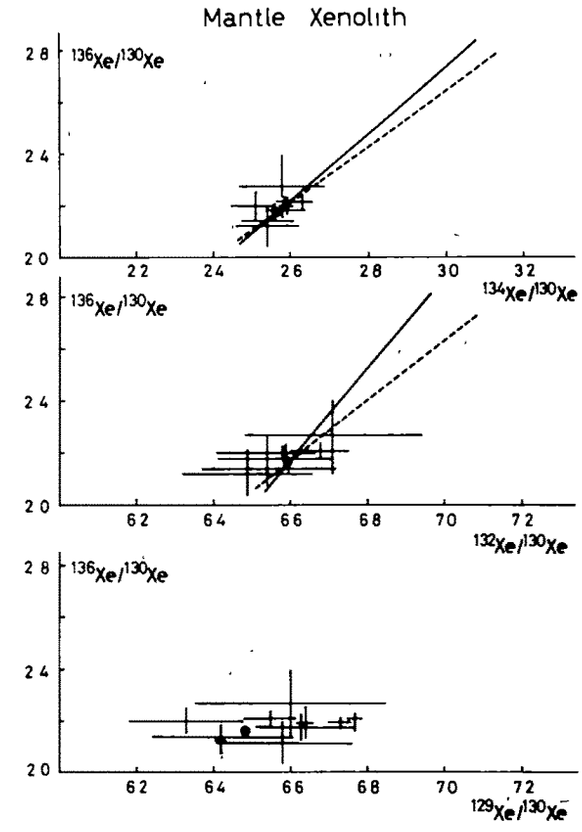

Fig. 3 Three isotope plots for mantle-derived xenoliths (data from refs 9, 10, 28) ●, Air Xe A slight excess may be seen in ^{129}Xe.

Xe closure time

In using radiogenic isotopes as chronological tracers, a fundamental problem is to identify when the parent–daughter element system closed. The nucleogenic Xe isotopes that are important in terrestrial Xe are spontaneous fissiogenic Xe (^{131}Xe, ^{132}Xe, ^{134}Xe, ^{136}Xe) from ^{238}U and ^{244}Pu and radiogenic ^{129}Xe. Once the system is closed for ^{129}I/Xe and ^{244}Pu/Xe ratios, Xe isotope evolution obeys a simple radioactive decay law and is predictable. Because our main concern here is the early history of the Earth and thus with I–Xe and Pu–Xe closure; we can disregard the ^{238}U–Xe system in much of the following discussion because of the long half-life of ^{238}U.

In gas of a solar composition, Xe isotope evolution would be negligible because of very low I/Xe and Pu/Xe ratios; only in condensed materials greatly depleted in noble gases would Xe evolution be significant. Theoretical treatments of early Solar System history typically conclude that condensation and fragmentation into planetesimals (bodies a few kilometres in diameter) would occur quite rapidly, on a 10^4-yr timescale at the Earth's orbit[18,19], but that accretion of planetesimals into the major terrestrial planets might take significantly longer, of the order of 10^7–10^8 yr (ref. 20). This is a significant time for short-lived ^{129}I and ^{244}Pu. While condensation and accretion result in closure of solid elements such as Pu and I, Xe closure might be established only after collisions among planetesimals, because impact shock could result in the effective degassing of volatiles[21]. In this way, it would be possible for early and late-accreting material to have significantly different Xe closure times and contribute significantly different amounts of radiogenic Xe, expecially ^{129}Xe, even if it all had the same basic chemistry and the same initial I/Pu ratio.

Interpretation

According to Pepin and Phinney[22,23], about 6.7% of atmospheric ^{129}Xe originates from the decay of ^{129}I, and 4.7% of atmospheric ^{136}Xe originates from the decay of ^{244}Pu. Subtracting these nucleogenic components from the air Xe composition, we can define a 'primary' air Xe (equivalent to "corrected atmosphere Xe"[23]); this is presumably the Xe composition at the time of isotopic closure. It is a straightforward matter to develop equations for the compositional evolution after closure and to include a single episodic degassing event. Using subscripts '0' for closure and 'd' for degassing, and setting $t_0 = 0$, we have for $0 \leq t \leq t_d$ (from Xe closure to degassing):

$$\frac{^{129}\text{Xe}}{^{130}\text{Xe}} = \left(\frac{^{129}\text{Xe}}{^{130}\text{Xe}}\right)_0 + \left(\frac{^{129}\text{I}}{^{130}\text{Xe}}\right)_0 (1-\exp(-\lambda_{129}t))$$
$$\frac{^{136}\text{Xe}}{^{130}\text{Xe}} = \left(\frac{^{136}\text{Xe}}{^{130}\text{Xe}}\right)_0 + \left(\frac{^{244}\text{Pu}}{^{130}\text{Xe}}\right)_0 {}^{136}\text{Y}_{\text{Pu}}(1-\exp(-\lambda_{244}t)) \quad (1)$$

where λ_{129} and λ_{244} are the decay constants for ^{129}I and ^{244}Pu and $^{136}Y_{Pu}$ is the yield of ^{136}Xe per decay of ^{244}Pu.

If the degassing occurred before ^{129}I and ^{244}Pu had decayed completely, Xe isotopic composition in the residue continued to evolve. If we assume that a fraction $(1-f)$ of the Xe was degassed at $t = t_d$, the evolution for $t > t_d$ becomes

$$\frac{^{129}\text{Xe}}{^{130}\text{Xe}} = \left(\frac{^{129}\text{Xe}}{^{130}\text{Xe}}\right)_0 + \left(\frac{^{129}\text{I}}{^{130}\text{Xe}}\right)_0 (1-\exp(-\lambda_{129}t_d)) + \frac{1}{f}\left(\frac{^{129}\text{I}}{^{130}\text{Xe}}\right)_0 \exp(-\lambda_{129}t_d) \times (1-\exp(-\lambda_{129}(t-t_d)))$$
$$\frac{^{136}\text{Xe}}{^{130}\text{Xe}} = \left(\frac{^{136}\text{Xe}}{^{130}\text{Xe}}\right)_0 + \left(\frac{^{244}\text{Pu}}{^{130}\text{Xe}}\right)_0 {}^{136}\text{Y}_{\text{Pu}}(1-\exp(-\lambda_{244}t_d)) + \frac{1}{f}\left(\frac{^{244}\text{Pu}}{^{130}\text{Xe}}\right)_0 {}^{136}\text{Y}_{\text{Pu}} \exp(-\lambda_{244}t_d) \times (1-\exp(-\lambda_{244}(t-t_d))). \quad (2)$$

Figure 4 shows a single-stage Xe-isotope evolution curve, for

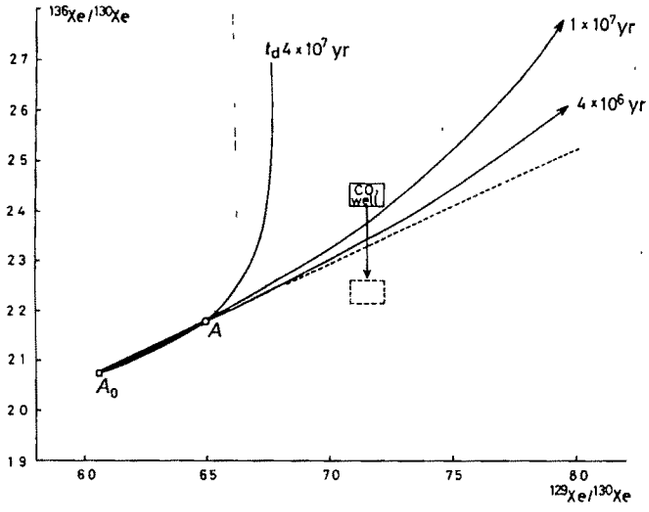

Fig. 4 Xe isotope evolution model in the Earth. *A*, Air Xe, A_0, primary air Xe (see text). A_0 is the Xe-closure time in the Earth Owing to ^{129}I and ^{244}Pu, Xe isotopes in the Earth had evolved along the paths A_0–A At t_d Xe was degassed into the atmosphere, where the Xe isotopic ratio was quenched to give air Xe (A). After t_d, Xe in the Earth has continued to evolve. The evolution curve is determined by specifying t_d. We also show the CO_2-well gas Xe (refs 4, 5). Solid rectangle, the range for the measured isotope composition; dotted rectangle, isotopic composition (maximum value) corrected for the ^{238}U-fissiogenic ^{136}Xe

which atmospheric Xe is assumed to be degassed at $t = t_d$. Although drawn for $f = 0.5$, the choice of f ($0 < f < 1$) does not significantly affect the general character of the evolution. Equation (1) clearly shows that the specification of t_d determines $(^{244}Pu/^{130}Xe)_0$ and $(^{129}I/^{130}Xe)_0$, as both $(^{136}Xe/^{130}Xe)_{air}$ and $(^{129}Xe/^{130}Xe)_{air}$ are assumed to be known. This situation can also be seen in Fig. 4: an evolution curve passing through A_0 (primary air Xe) and A (present air Xe) can be uniquely determined by specifying t_d. The shorter the t_d, the further the curves grow after the degassing, since shorter t_d requires greater I/Xe and Pu/Xe and much of the decay occurs after the degassing. Note that Xe isotope composition in any degassed region ($t_d > 0$) must be located in the region above the dotted line, that is, the extension of the line connecting A_0 and A in Fig. 4; qualitatively, the ratio of fission ^{136}Xe to radiogenic ^{129}Xe must increase with time because of the greater half-life of ^{244}Pu.

Let us now consider the CO_2-well gas Xe. Figure 4 plots the CO_2-well gas Xe both as measured and as corrected for ^{238}U fissiogenic ^{136}Xe. Phinney *et al.*[4] estimated that at least 80% (and perhaps all) of the excess ^{136}Xe is due to ^{238}U-fission (rather than ^{244}Pu fission). We have re-estimated the fraction of the ^{238}U-contribution to the excess ^{136}Xe using a least-squares method, with the result that it is at least 80%. Figure 4 shows that the CO_2-well gas Xe corrected for ^{238}U-fission lies below the dotted line, where the correction involves subtracting 80% of the excess $^{136}Xe/^{130}Xe$, relative to the air ratio, from the observed ratio (that is $(^{136}Xe/^{130}Xe)_{corr} = 2.448 - (2.448 - 2.1747) \times 0.8 = 2.2294$). The corrected value should be an upper limit, as the ^{238}U-fissiogenic contribution is likely to be larger than 80%. By the above argument, this observation indicates that the CO_2-well gas Xe (corrected for ^{238}U fission) was not derived from the residue from which atmospheric Xe was degassed, nor entirely as a mixture of air with Xe from this residue, because such Xe must lie above the dotted line.

The fundamental difference between the source region of the well-gas Xe and that of air Xe is that the former must have had a smaller $(^{244}Pu/^{129}I)_0$ value. It is easy to show that the Xe isotope evolution curve which evolved from A_0 to terminate at the nominally corrected well-gas composition is uniquely specified by a $(^{244}Pu/^{129}I)_0$ value of 2,105, which is much smaller than the minimum permissible value for the source of atmospheric Xe ($(^{244}Pu/^{129}I)_{min} = 3{,}306$, corresponding for $t_d \gg 1/\lambda_{244}$). This difference may have resulted from chemical differentiation in the Earth or from chemical heterogeneity among the planetesimals which accreted to form the Earth. In the former case, the chemical differentiation must have occurred before ^{129}I or ^{244}Pu had decayed, that is, within a few tens of millions of years after the formation of the Earth. In the latter case, the difference in $(^{224}Pu/^{129}I)_0$ among planetesimals may reflect a variation in the Xe-closure time of different planetesimals. If the time lag is responsible for the difference in the $(^{244}Pu/^{129}I)_0$ ratio, the time interval required can be estimated from

$$\left(\frac{^{244}Pu}{^{129}I}\right)_{0,outer} \Big/ \left(\frac{^{244}Pu}{^{129}I}\right)_{0,inner} = \exp\{(\lambda_{129} - \lambda_{244})\Delta t\} \quad (3)$$

Setting $(^{244}Pu/^{129}I)_{outer} > 3{,}306$ and $(^{244}Pu/^{129}I)_{inner} = 2{,}105$ in the left-hand side of equation (3). We obtain $\Delta t > 1.4 \times 10^7$ yr.

Earth's early history

The excess ^{129}Xe in some terrestrial materials indicates that the region from which the excess ^{129}Xe was derived must have been isolated from the atmosphere for nearly the whole history of the Earth. We argued above against the commonly held view[6,7,13–15] that the source region for the excess ^{129}Xe in the CO_2-well gas represents the degassed mantle from which air Xe was derived.

We propose the following scenario for interpreting coherently the available Xe isotope data. The Earth formed by accretion of impacting planetisimals. Planetesimals were originally formed by the fragmentation process[24], underwent mutual collision to grow further and finally impacted onto the Earth. The early planetesimals constituted the inner part of the Earth. As the accretion time of the Earth is plausibly at least a few tens of millions of years[18,19] and the time of the final impact of the planetsimals onto the Earth must be an upper limit to their Xe-closure time, there could well have been a few tens of millions of years time gap in Xe-closure time between the inner and outer regions of the Earth. Hence, we expect that the inner part of the Earth had smaller $(^{244}Pu/^{129}I)_0$ as well as larger $(^{244}Pu/^{130}Xe)_0$ and $(^{129}I/^{130}Xe)_0$ ratios. If we assume that the CO_2-well gas Xe (except for the ^{238}U fission component) was derived from the inner part of the Earth, while air Xe was degassed from the outer region, we could explain why the CO_2-well gas Xe is characterized by excess ^{129}Xe but not a corresponding excess of ^{244}Pu-derived $^{131-136}$Xe. The comparison between air Xe and CO_2-well gas Xe then gives about 1.4×10^7 yr for the minimum time interval between the formation of the two regions. If the timescale for atmospheric degassing is of the order of 10^8 yr, as inferred from very high $^{40}Ar/^{36}Ar$ ratios in the upper mantle[25], then the upper-mantle Xe composition should be nearly the same as the atmospheric Xe composition.

Excess ^{129}Xe has been reported in some mantle-derived samples. The largest excess ^{129}Xe reported for terrestrial materials is for MORB by Allègre *et al.*[7] who argued that the excess ^{129}Xe in MORB is indicative of very early degassing of the MORB source region. The argument can be examined by means of Fig. 4. However, the difficulty in identifying ^{244}Pu-fissiogenic Xe does not allow such a test. Hence, until the origin of the excess $^{131-136}$Xe is resolved, the conclusion by Allègre *et al.* should be treated with caution.

The high $^{40}Ar/^{36}Ar$ ratios in MORBs relative to air Ar are not inconsistent with the rapid timescale for degassing (within a few tens of millions years after Earth's formation) argued by several authors on the basis of the excess ^{129}Xe in the mantle-derived materials[6,7,13–15]. However, note that while the high $^{40}Ar/^{36}Ar$ ratio has been established throughout the Earth's history owing to the much slower decay of ^{40}K, the excess ^{129}Xe was established soon after the formation of the Earth. In the upper mantle, where material movement such as mantle convection and subduction are likely to have operated throughout geological time, it is difficult to suppose that the early established excess ^{129}Xe could have survived these geological disturbances. The mixing of subducted materials into the mantle is especially difficult to reconcile with the persistent existence of excess Xe

in MORB because, unlike lighter noble gases, Xe is notoriously 'sticky' and is likely to be carried down into the mantle with the subducting ocean sediments, which have 2-4 orders of magnitude enrichment of Xe relative to common volcanic rocks[26]. Hence, it may be more reasonable to suppose that the excess ^{129}Xe observed in MORBs (and also in other mantle-derived materials) did not originate in the degassed upper mantle, but was transported there from some other region (possibly from the deeper mantle). This source had been isolated from the mantle-atmosphere system for almost the whole history of the Earth as shown by the presence of excess ^{129}Xe in the CO_2-well gas Xe.

Quaternary structure of the acetylcholine receptor

A. Brisson & P. N. T. Unwin

Service de Physique, Groupe Structures, Département de Recherche Fondamentale, Centre d'Etudes Nucléaires, Grenoble 38041, France and Department of Cell Biology, Stanford University School of Medicine, Stanford, California 94305, USA

The five membrane-spanning subunits of the acetylcholine receptor have been resolved in electron microscope images and are shown to lie at pentagonally symmetrical positions around the channel over a large fraction of their length. The channel consists of a wide synaptic portion and a narrow portion extending through the membrane into the interior of the cell.

SIGNALLING between excitable cells is commonly mediated by the release of neurotransmitters, which bind subsequently to receptors in the target membranes and induce in them a change of permeability. The nicotinic acetylcholine receptor, the best understood such receptor, effects the change by opening a channel in the membrane through which cations, principally sodium and potassium, diffuse. This action is initiated by the cooperative binding of neurotransmitter to the α-subunits, the two smallest of five (stoichiometry $\alpha_2\beta\gamma\delta$) assembled in a ring around the channel (see refs 1-3 for review).

The complete amino-acid sequences of the four types of polypeptide comprising this receptor have recently been deduced[4-7] and indicate extensive homology between the subunits (see ref. 8 for review). Predictions based on these data suggest a common motif of secondary structure for the portions of the subunits inside the lipid bilayer[9,10], with features having important implications concerning the movement of ions through the channel and the mechanism of the gating event[11,12]. An understanding of the molecular details now requires direct structural information on the different transitional states.

Here we report on a quaternary configuration of the acetylcholine receptor, determined by three-dimensional electron image analysis of tubular crystals grown from native membrane vesicles. Previously, a pentagonal molecular outline had been resolved in individual images of stained tubes, suggesting that the subunits are disposed regularly around the channel[13]. The three-dimensional maps obtained by combining information from many images now reveal details of the subunits and of the channel at different levels throughout the structure. We demonstrate that there is indeed an approximate 5-fold axis of symmetry along the channel axis over a large fraction of the molecule extending from within the lipid bilayer into the synaptic cleft.

Table 1 Three-dimensional data from images of tubes

	Frozen	Stained
No. of images*	35	52
Range of tilt angles	0-60°	0-65°
No. of independent lattice lines†	21	24
No. of Fourier terms used in synthesis‡	208	271
Average phase error/image§	13.5°	11.9°

* Values for the axial ratio b/a and included angle γ were 1.787 ± 0.01, $120.17 \pm 0.19°$ (frozen) and 1.797 ± 0.01, $117.33 \pm 0.48°$ (stained), from 20 measurements, with a, b and γ as defined previously[13]. Thus, the ratio of lateral to longitudinal dimensions is ~5% smaller for the stained than for the frozen tubes.

† Data include all significant lattice lines (except for the (0, 0)) to a resolution of 25 Å; these are the (0, 2), (0, 3), (0, 4), (0, 5), (1, −5), (1, −4), (1, −3), (1, −2), (1, −1), (1, 0), (1, 1), (1, 2), (1, 3), (2, −5), (2, −4), (2, −3), (2, −2), (2, −1), (2, 0), (3, −3), (3, −1) lattice lines in both cases, and in addition the (0, 1), (3, −5), (3, −2) for the tubes in stain.

‡ Obtained by sampling the continuous amplitude and phase curves at regular 0.0025-Å^{-1} intervals.

§ Based on cumulative comparisons of individual peaks over a range of 0.003 Å^{-1} along the lattice lines.

Data collection and analysis

The tubes, which were prepared from the electric organ of the ray *Torpedo marmorata*, are composed of receptors arranged in a p2 surface lattice and oriented with the synaptic side outwards[13]. They are flattened against the support film during preparation (see Fig. 2 legend), forming two almost planar superposed layers (Fig. 1). Images of the tubes in frozen solution and in negative stain were obtained to provide information on the complete protein and the hydrophilic surfaces, respectively.

For the analysis, all the selected tubes had surface lattices in orientations close to the example in Fig. 1*b*; therefore, variations in their unit cell parameters were less than described previously[13]. The tubes were tilted at angles of up to 65° to the incident electron beam and the amplitudes and phases of the Fourier components were determined to a resolution of 25 Å from digitized areas of these images. Data were then combined cumulatively by standard methods[14] to map the continuous variations of amplitude and phase along each reciprocal lattice line (Fig. 2). The three-dimensional Fourier syntheses were from the terms obtained by sampling these curves at regular intervals

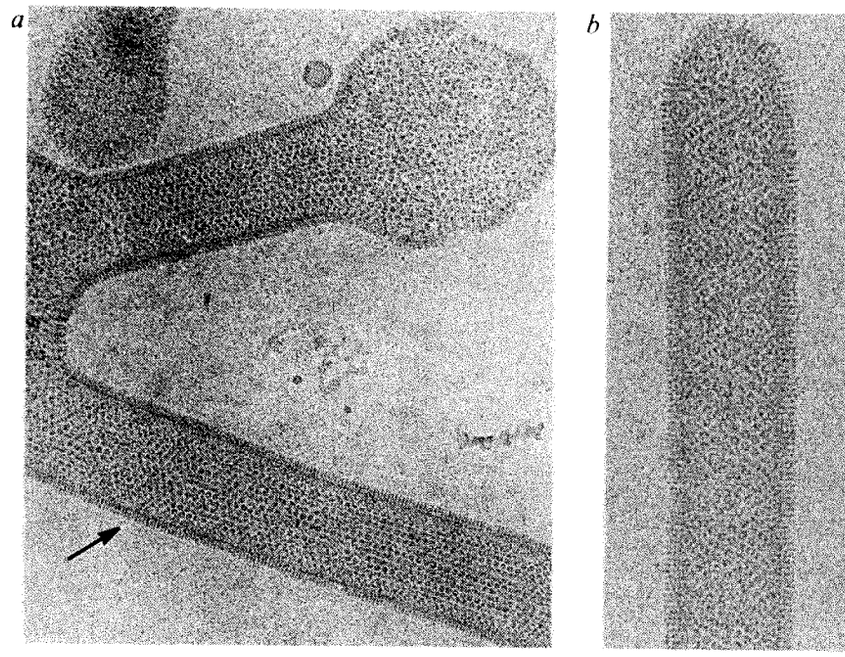

Fig. 1 Electron microscope images of tubular crystals of acetylcholine receptor embedded in thin films of frozen buffer (100 mM Tris-HCl, *p*H 6.8). The complex patterns arise from superposition of *en face* views of the receptors located on the top and bottom surfaces. Striated zones at the tube borders are a result of the receptors being viewed more nearly from the side; when aligned parallel to the tube axis, as in *a*, the receptors in these zones form distinct 120–140-Å wide bands (arrow) and seem to be viewed exactly from the side. Magnifications: *a*, ×112,000; *b*, ×182,400.

and assuming the unit cell dimensions in the plane of the membrane to be $a = 90.0$ Å, $b = 160.8$ Å, $\gamma = 120.2°$, determined from the frozen specimens. The densities synthesized from the stained specimens were multiplied by −1 to correct for their opposite contrast. Further details are given in Table 1.

The similarity between the two three-dimensional maps was evaluated by comparing sections at various levels throughout the two structures. The sections were parallel to the plane of the membrane and the comparisons included all the densities in a single unit cell. The best overall correlation was achieved with a relative displacement of 11 Å perpendicular to the membrane between the origins of the two maps, reflecting differences between the centres of scattering density for the two cases. Corresponding values for the correlation coefficients were >0.8 over most of the ~140 Å length in which features were clearly contrasted (Fig. 3), except for a narrow zone identified as the hydrophobic core of the bilayer (see below). Hence, with the exception of this zone, the two maps resemble each other closely.

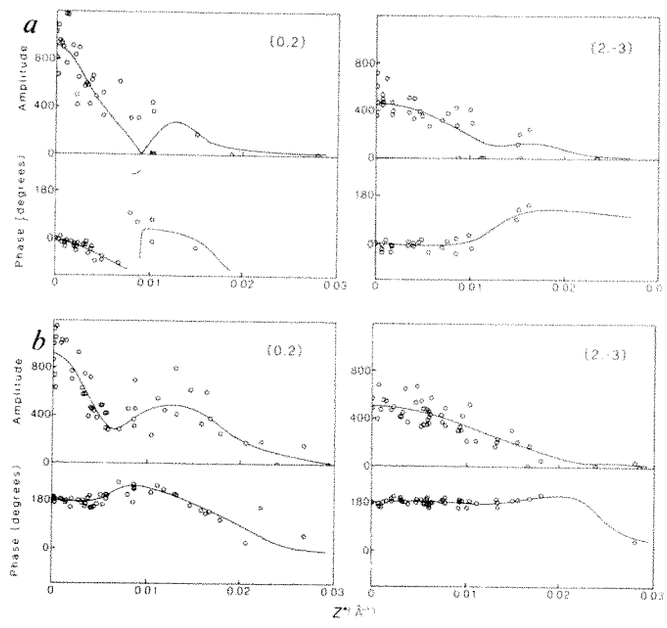

Fig. 2 Comparison of amplitude and phase variations along typical lattice lines after combining images from tubes in: *a*, ice; *b*, stain, according to the 2-sided plane group p21. The continuous curves through the data points were computed by a least-squares method with amplitudes weighted according to the reliability of the corresponding phases[22]. Z^* is the distance from the midpoint of the lattice line.

Methods. Tubes were prepared as described previously[13] and applied to carbon support grids rendered highly charged by glow discharge in amylamine vapour[23]. For freezing, grids were blotted with filter paper for 4 s, then plunged rapidly into liquid ethane cooled to below −130 °C; for staining, they were washed in 2% sodium phosphotungstate *p*H 7.2 and then dried. Frozen specimens were stored under liquid nitrogen and later examined in a Philips EM400 electron microscope using a cold holder maintained at −174 °C. The electron optical magnifications were ×40,800 (ice) and ×28,500 (stain), and images were recorded at 100 kV on Kodak SO163 film developed for 8 min in concentrated D19 developer. A Philips low-dose kit was used to minimize radiation damage and to ensure that all images incorporated in the three-dimensional datasets were of tubes which had received total doses of no more than ~15 electrons per Å^2. Optical adjustments were performed at a nominal magnification on the screen of ×90,000 to minimize variability in focus level from one image to the next. Tube images were evaluated by optical diffraction (see ref. 13) for the extent of structural preservation and degree of flattening, and then evaluated further by computer. For the computer analysis, densitometry and Fourier transformation of the central portion of the tubes were as described previously[13]; criteria for selection of images for incorporation into the three-dimensional datasets included the strength of the diffraction maxima above background and the accuracy with which they fit a regular two-dimensional net. Also, areas of interest were considered unsuitable if the corresponding under-focus values (see below) were outside the range 8–16,000 Å. Variability in lattice parameters between tubes necessitated the use of special methods to derive accurate values of tilt angle and axis. All images were recorded in pairs. With the frozen specimens (*a*) the second image of each pair was of the carbon support film only, after intensifying the electron beam to sublimate the ice. Diffraction patterns from these images displayed a series of concentric rings[24] extending to spacings <10 Å. Defocus values could be measured locally with an accuracy of ±250 Å over a wide range, based on matching such patterns against a calibrated set. Tilt parameters were computed from the defocus values measured at the four corners of each film. Typical errors, estimated by comparing values from the four alternative planes passing through the different sets of three points, were 2° in tilt angle and 4° in direct of tilt axis, slightly larger errors applying to smaller tilts (<10°). With the stained specimens (*b*), the second image was recorded (with negligible in-between irradiation) at another angle of tilt, differing from the first by a pre-selected amount (typically 15°). Tilt parameters were computed from the changes in reciprocal lattice geometry between the two images. In this case the independent values obtained from the two sides of each tube could be compared, and the errors indicated were found to be of similar magnitude as in the first method.

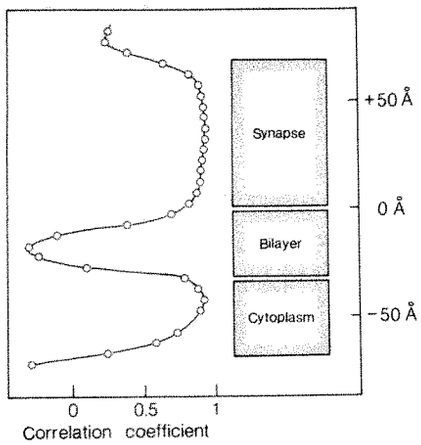

Fig. 3 Plot of correlation coefficients obtained by comparing sections from the three-dimensional maps of the frozen and stained tubes. The ordinate indicates the various levels through the structure, perpendicular to the membrane, at which the values were calculated. The hydrophobic core of the bilayer is identified by a zone showing poor correlation. The synaptic and cytoplasmic domains show good correlation over most of their extent; the poorer correlation near the extremities of the structure may be due to slight flattening of the stained receptors in the direction normal to the membrane plane.

Exact correspondence, particularly at the extremities of the structure, is not expected because of minor alterations resulting from, for example, drying of the stain[15].

Structure of the receptor

The three-dimensional map calculated from the frozen tubes (Fig. 4) shows details of the entire receptor molecule, both in the lipid bilayer and in the aqueous surroundings on either side. The molecule is resolved into five rod-shaped subunits (Fig. 4*a*) of about equal cross-section, which lie predominantly perpendicular to the membrane plane. The five subunits are contained within a ~140-Å-long by ~80-Å-diameter cylindrical shell, and delineate a water-filled opening, presumed to be the channel, along the axis of this cylinder.

This map does not distinguish between the portion of the oligomer embedded in the bilayer and those protruding outside, because lipid and water contribute about equally to the image contrast at low resolution. The portions, however, can be identified by correlation with the map from the stained tubes. A ~ 30-Å zone in that map appears almost featureless—neither the channel nor the surrounding protein is visible—and must correspond to the hydrophobic core of the bilayer, which is inaccessible to the stain. Consequently, there is a length of ~30 Å, the correlation coefficients of which have particularly low values (Fig. 3), and the matching of structural detail is poor (Fig. 5*b*) compared with that on either side (Fig. 5*a*, *c*). Thus the correlation places the hydrophobic core nearest to the cytoplasmic end of the structure, leaving a length of 35–45 Å protruding on this side, compared with ~70 Å on the other.

The channel is nearly 30 Å wide at the synaptic end of the oligomer (Fig. 4*b*, uppermost), but becomes too narrow at the cytoplasmic end to be seen. The way in which the channel narrows cannot be discerned accurately at the resolution achieved in the present study, but the abrupt exclusion of the anionic stain at the level of the bilayer surface, on the synaptic side, suggests that a large reduction in its diameter occurs in this region.

The cross-sectional area of the membrane-spanning portion of the subunits is of interest because of the different models that have been proposed for the internal structure of this portion. To estimate this value, we assumed the molecular boundary to be at the contour level for which the total enclosed volume of glycosylated protein is 350,400 Å^3, calculated from the composition[8]. The corresponding cross-sectional area per subunit was 540 Å^2, averaged over the extent of the bilayer, whereas for the

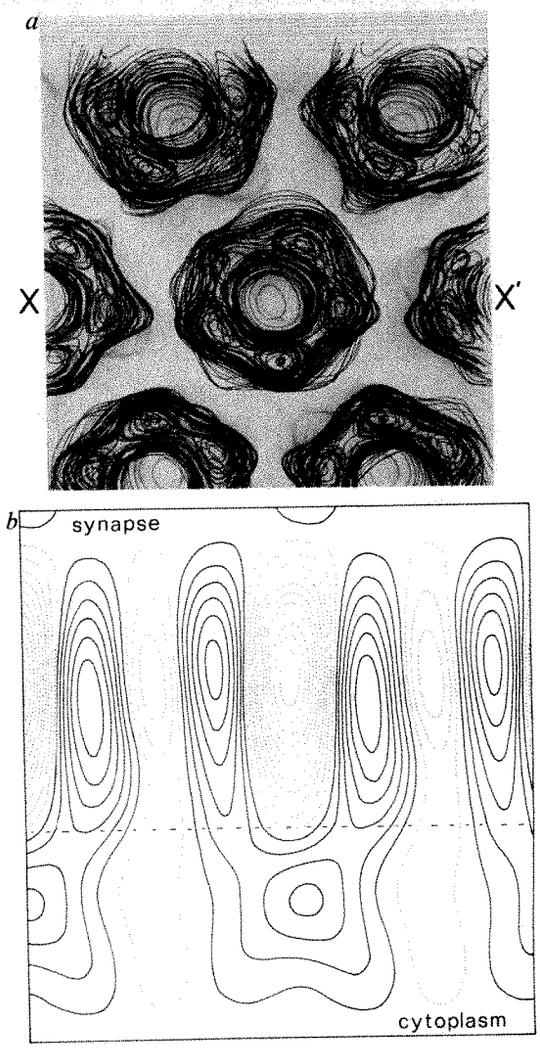

Fig. 4 *a*, Three-dimensional map of receptor molecules in the crystal lattice as they would appear viewed from the synaptic cleft; successive sheets are of sections parallel to the membrane plane separated by spaces corresponding to 5 Å. The centre-to-centre separation between receptors in the horizontal direction corresponds to 90 Å. *b*, Section along the line XX′ in *a*, through the channel axes and perpendicular to the plane of the sheets; the central plane of the bilayer is indicated by the broken line. The phosphotungstate stain is excluded from the channel at a level ~15 Å above this line. Only contours corresponding to regions in which protein is concentrated are shown in *a*; all contours are shown in *b*. The outermost, full-line contours in *a* and *b* are close to the zero contour in Fig. 5 and represent the molecular boundary consistent with the volume calculated from protein composition.

synaptic and cytoplasmic portions it was 550 and 375 Å^2, respectively. As an approximate check on the value for the cross-section in the bilayer, a three-dimensional map was also calculated with approximate terms included for the central (0, 0) lattice line. These terms were derived from transforms of the striated border regions of tubes, as in Fig. 1*a*, using the (1, 2) lattice line (associated with the striation periodicity) to set the scale for the amplitudes and the origin of the phases. From the molecular boundary now on an absolute scale, a mean value of 500 Å^2 was obtained for the subunit cross-section in the bilayer, in reasonable agreement with the estimate based on protein composition.

Pentagonal symmetry

The five subunits are arranged regularly around the central axis of the receptor for much of its length, so that the structure has approximate pentagonal symmetry about this axis. The r.m.s. departures from exact symmetry are, respectively, 1.2 and 1.4 Å in radius and azimuth averaged over the portion of the protein

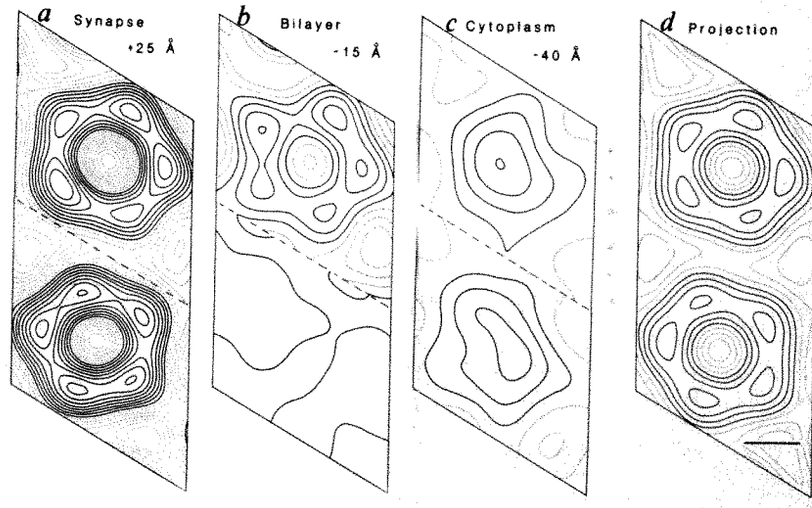

Fig. 5 *a–c*, Sections at different levels through a unit cell from the three-dimensional maps; *d*, the projected structure in frozen solution. The pair of receptors shown is thought to correspond to the δ–δ subunit linked physiological dimer[13]. In *a–c* the regions and levels indicated relate to Fig. 3; contours in the upper and lower halves refer to the frozen and the stained tubes, respectively; the two halves are related by symmetry as in *d*. The positive and zero contours are indicated by continuous lines, the negative contours by dotted lines; data from the (0, 0) lattice line, not included in the Fourier syntheses, have only a minor effect on the position of the zero contour. The scale bar (bottom right) corresponds to 25 Å.

in the hydrophobic core of the bilayer, and 0.8 and 1.9 Å averaged over the contiguous ~30-Å portion on the synaptic side. The total extent of this symmetrical region comprises about half of the length of the molecule, sufficient to dominate its appearance in projection (Fig. 5*d*). Nearer to the extremities, particularly on the cytoplasmic side, the pentagonal symmetry is not as marked, suggesting more profound structural differences between individual subunits in these regions? On the cytoplasmic side the distribution of mass about the axis of the oligomer is asymmetrical (Fig. 5*c*) and the cross-section is smaller, as if the parts of the subunits here have different lengths.

Discussion

The tubular crystals have led to a quantitative description of the quaternary structure of the acetylcholine receptor in a natural lipid-containing environment. The receptor is a cylindrical molecule having almost constant lateral dimensions (mean diameter ~65 Å) except for the part on the cytoplasmic side of the bilayer, which is narrower. It is composed of five rod-shaped subunits, each up to ~140 Å long. They lie approximately perpendicular to the membrane plane and are asymmetrically placed in relation to the bilayer, having two to three times more of their combined mass on the synaptic than on the cytoplasmic side. Subunits are similar in cross-section and are arranged symmetrically around a central opening, the presumed channel through which cations diffuse. The channel is partitioned equally into a wide (25–30-Å diameter) portion at the synaptic end of the structure and an unresolved narrow portion extending through the membrane into the interior of the cell.

In previous studies, electron images of stained molecules, viewed *en face* and from the side, have been used to deduce the overall shape of the protein and channel[16,17,25–27]. Morphological observations have also been combined with X-ray or neutron diffraction data to obtain models for the cylindrically averaged distribution of mass[18,19]. Seen most directly in frozen solution, the molecule appears more elongated and more angular in shape than has generally been supposed.

Identification of the membrane-spanning portion of the structure (Fig. 3) partitions the protein mass on either side in a way that is consistent with models inferred from the amino-acid sequences. However, the probable correctness of different models cannot be evaluated on this basis because of the possibility that the extrinsic cytoplasmic protein of apparent molecular mass 43,000 (ref. 20), thought to be present in the tubes, is bound regularly to the crystallized receptor and contributes some extraneous mass.

A striking aspect of the entire oligomer, previously suspected[1] but not seen until the present study, is that the subunits are arranged in almost equivalent positions around the channel, conferring on the structure an apparent high degree of pentagonal symmetry. This is most exact in the lipid bilayer and over a contiguous ~30 Å region on the synaptic side, and may be even more extensive than observed because minor errors in our data would make it less pronounced. Such symmetry, combined with the observed amino-acid sequence homology, makes it probable that the individual subunits share common features of tertiary organization over the lengths that they are in contact. These properties could be important in facilitating a coordinated movement of all subunits around the channel, such as may occur in switching between different transitional states[8].

The resolution of the analysis described here is insufficient to elucidate the internal structure of the subunits, but the observed details are consistent with models speculating that their membrane-spanning portions are composed of equal numbers of closely packed α-helical rods, or other configurations of the polypeptide chain[28]. The value suggested for the subunit cross-section in this region, 500–540 Å^2, favours models with five α-helices extending through the membrane[10,12] (assuming, for example, a packing similar to that in bacteriorhodopsin[21]).

We thank Dr P. Swann, Gatan Inc., for making available an electron microscope cold holder, and Dr C. Cazaux and his colleagues at the Institut de Biologie Marine, Arcachon for supplying *T. marmorata*. The research was supported by EMBO and Phillipe Foundation Fellowships to A.B. and by a grant from the NIH.

Direct evidence using tritium data for throughflow from the Pacific into the Indian Ocean

Rana A. Fine

Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149, USA

Basin-wide exchange between the Pacific and Indian oceans through the Indonesian Archipelago has received attention, both in relation to the oceans' role in the Southern Oscillation[1] and in efforts to balance the salt and mass fluxes of the individual basins[2–5]. Wyrtki[6] made the first indirect estimate using hydrographic data of a mean annual transport from the Pacific to the Indian Ocean of 2×10^6 m^3 s^{-1} in the upper 200 m. Recent estimates have been considerably higher: 14×10^6 m^3 s^{-1} by Piola and Gordon[2], 10×10^6 m^3 s^{-1} by Godfrey and Golding[5], and 5×10^6 m^3 s^{-1} by Godfrey and Ridgeway[3]. However, Wunsch *et al.*[4] concluded that, as a result of inverse calculations on sections across the South Pacific, there was a negligible throughflow transport. A meridional maximum in bomb-produced tritium (half-life 12.4 yr) observed in the South Equatorial Current (SEC) of the Indian Ocean is used here to show direct evidence that in the mean there is a net transport (in the upper 300 m) of 5×10^6 m^3 s^{-1} from the Pacific into the Indian Ocean.

The use of bomb tritium, which is found in the oceans in the form of HTO, has become increasingly popular[7–9] as a conservative tracer for oceanic circulation processes with decadal time scales. Decay-corrected tritium data collected during the Geochemical Ocean Sections (GEOSECS) Expeditions[10] are anomalously higher in the South Indian than either the South Atlantic or South Pacific oceans. The presence of the Indian subcontinent at 25° N rules out a North Indian Ocean source, the asymmetric fallout pattern[11,12] rules out a Southern Hemisphere source. Toggweiler and Trumbore[13] found anomalously high bomb-produced ^{90}Sr in Indian Ocean corals which they attribute to throughflow of North Pacific water.

Figure 1 is a map showing tritium at the surface of the Indian Ocean[10]. Pre-bomb surface values may be considered to be <1 TU (1 TU = $10^{18}\times$mole fraction of (^{3}H/^{1}H)). Experimental error is <0.1 TU. Tritium values are highest (>6 TU) in the Bay of Bengal as result of runoff; yet the high values are confined to a shallow surface layer. Contrast the Arabian Sea where the highest evaporation in the Indian Ocean occurs, surface waters there contain 2.5 TU. In the Southern Hemisphere, the highest tritium values are found in the westward-flowing SEC located between 10 and 20° S. Tritium >3.5 TU is found from about 5° N to 30° S, and it coincides fairly well with an intrusion of low salinity observed throughout the year[14]. The tritium contours in Fig. 1 generally follow an east-west pattern because the first order transport of water is advection by the zonal wind-driven currents.

Figure 2 is a map showing tritium at 200 m in the thermocline of the Indian Ocean[10]. Tritium values have decreased to <1 TU in the Bay of Bengal showing that high tritium in the runoff there is confined to a shallow surface layer. Its effect is only local because of dilution during subsequent mixing with low ambient levels of tritium. The zonal patterns at 200 m are similar to those at the surface; highest values are shifted slightly polewards. This is probably due to poleward contraction of the gyre with depth[15], and perhaps also downwelling south of 15° S. Thus, at the time of sampling, bomb tritium had already mixed well into the thermocline of the subtropical gyre resulting in a maximum in the region of the SEC as a prominent feature down to 300 m. Most of the transport in the SEC occurs above 300 m (ref. 14).

The intrusion of low salinity/high tritium water into the South Indian Ocean is due to a combination of throughflow from the North and South Pacific, and precipitation[6] which is very high near Indonesia. In general, twice as much tritium makes its way into the oceans through molecular exchange as through rain[12,16]. In regions where precipitation and runoff are high, unusually low salinities and high tritium will be found, for example, the Bay of Bengal. However, the high tritium in the Bay of Bengal is confined to a shallow surface layer and has only a local effect. In addition, the tritium measured in precipitation in the few years before the GEOSECS Indian Ocean expedition was twice as high over the Bay of Bengal as that measured in precipitation over Indonesia[17]. This would result in even lower surface ocean tritium in the component from precipitation than in the Bay of Bengal runoff water. Thus, precipitation is not the main source for the low salinity/high tritium intrusion.

Wyrtki[6] concluded from hydrographic data that, even though the surface currents in the Indonesian Archipelago are subject to monsoonal variations, in all layers (except for the oxygen minimum) movement of water from the Pacific (via the Timor Current) to the Indian predominates. The transport has decreasing intensity with depth. Although the upper waters in the western tropical South Pacific contribute to the throughflow, they are too low in tritium[8] and high in salinity[18] to be a major source. On the other hand, GEOSECS tritium in the Pacific North Equatorial Current (NEC)[8] was twice as high as the South Indian Ocean. Maps by Wyrtki[6] and Tsuchiya[14] show some of the westward-flowing NEC turning south near Mindano, both feeding into the North Equatorial Counter Current and

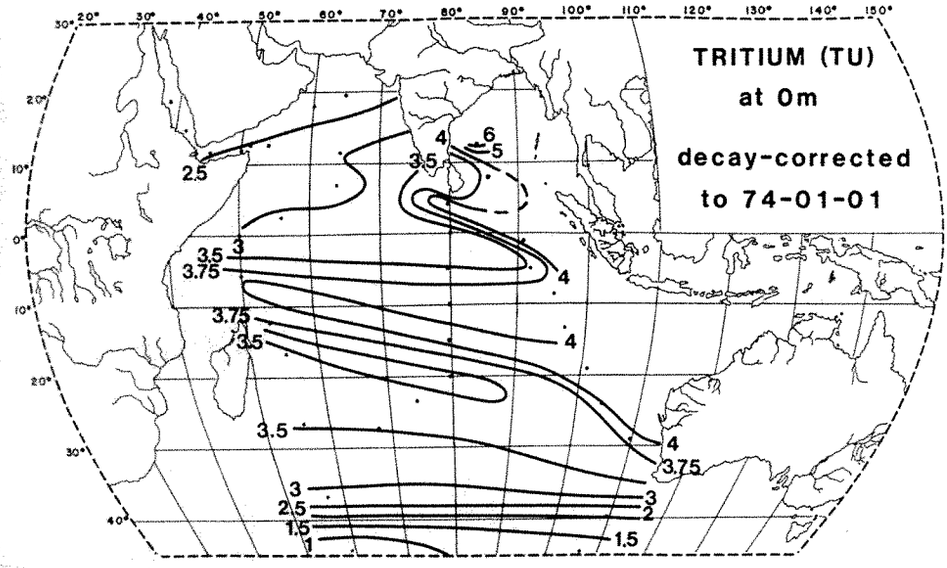

Fig. 1 Map of tritium (TU) at the surface of the Indian Ocean decay-corrected to 74-01-01. Data were collected as part of the GEOSECS program and analysed by Ostlund and Brescher[10]. •, Station locations.

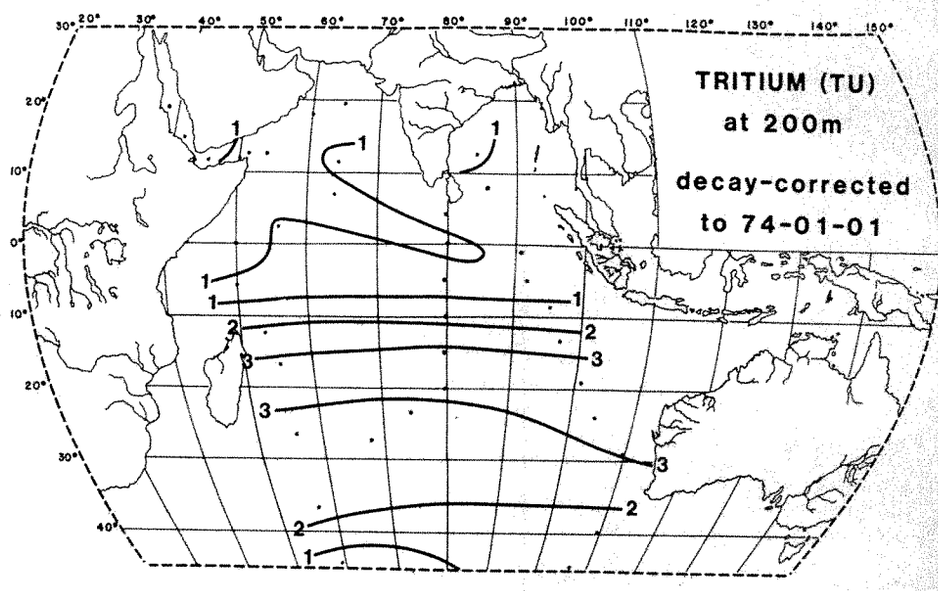

Fig. 2 Map of tritium (TU) at 200 m in the Indian Ocean decay-corrected to 74-01-01. Data were collected as part of the GEOSECS program and analysed by Ostlund and Brescher[10] (1982). •, Station locations.

entering the Indonesian Archipelago. Temperature and salinity near Mindano correlate with those in the western basins of the archipelago[5,6], in agreement with the idea of the North Pacific being a major source for the low salinity/high tritium intrusion in the Indian Ocean.

The additional information obtained when tritium is used as a tracer for oceanographic processes is particularly important for this problem because it provides an integrated picture of the decadal mean circulation. Tritium data[10] are combined with annual averages of temperature and salinity[19] into a box model to calculate the net transport from the Pacific into the Indian Ocean. The meridional extent of the box is chosen from 10 to 20° S and the depth range is 0-300 m; that region is fairly homogeneous in water mass properties and it encompasses most of the transport of the SEC. The eastern and western extent of the box are determined by geography—the Indonesian Archipelago and Madagascar.

The box model calculation[20] assumes that mass and chemical balances within the box are entirely consistent with pure advection. The first-order physics are:

$$u\frac{\partial C}{\partial x}+v\frac{\partial C}{\partial y}=\frac{\partial C}{\partial t}-\lambda(C) \qquad (1)$$

where according to convention u is the advection in the east (x)/west direction, v is the advection in the north (y)/south direction, C is the concentration, t is time, and λ is the decay term for tritium. If equation (1) is integrated over the volume (V) of the box then:

$$C_N v_N A_N + C_S v_S A_S + C_E u_E A_E = \frac{\Delta C}{\Delta t} V - \lambda C V \qquad (2)$$

where the C_is represent the average concentrations and the A_is represent the areas along the boundaries of the box. Table 1 gives the actual values for C_is which were obtained by integrating the data[10,19] observed along the boundaries of the box. Equation (2) is written for volume, salinity, temperature and tritium, giving a total of four equations and three unknowns. Using a least squares regression it may be solved for the advective velocities: v_N, v_S and u_E.

The air-sea exchange ($\Delta C/\Delta t$) may be evaluated using literature values. The net freshwater loss to the atmosphere by the Indian Ocean between 10 and 20° S calculated by Baumgartner and Reichel[21] is 0.14×10^6 m^3 s^{-1}. The heat flux between 10 and 20° S in the Indian Ocean estimated by Talley[22] was a net loss from the ocean to the atmosphere of 2 W m^{-2}.

Rates of addition of tritium by precipitation and vapour exchange to the South Indian Ocean are given in 5° latitude bands by Weiss and Roether[12]. When averaged over the time of the bomb transient, the deposition rate for the region 10-20° S is balanced by tritium decay to within the 30% error given for the deposition rate. Although subsurface observations of tritium are only available from the GEOSECS expedition for the Indian Ocean, there are observations spanning at least 10 yr in the NEC, which is the source region for the low salinity/high tritium intrusion. After 1974, decay has balanced input in the NEC[23], because we were already on the flat part of the deposition curve. Therefore, it is reasonable to consider the surface and subsurface tritium in a steady state.

The results of the regression together with the statistical errors in the coefficients are given in Table 1. The net transport into the box across the eastern boundary corresponds to the throughflow from the Pacific into the Indian Ocean; it is $5.1\pm0.4\times10^6$ m^3 s^{-1}. There is a small net northwards transport across 10° S (out of the box) of $-2.4\pm0.1\times10^6$ m^3 s^{-1} and a small net southwards transport across 20° S (out of the box) of $-2.6\pm0.4\times10^6$ m^3 s^{-1}. The north/south transports are difficult to assess physically as they encompass the surface Ekman poleward flow and part of the equatorward convergent geostrophic flow, as well as the branching of the SEC at its western terminus. A possible explanation for the integrated net northwards flow across 10° S could be related to the fact that Madagascar extends only to 10° S. Schott (personal communication) has recently found a strong northwestwards current at the northern tip of Madagascar.

Using the same data as described above, the model was run for a box 0-100 m deep encompassing the mixed layer. The

Table 1 Average concentrations and resultant net transports calculated from a box model for the region 10-20° S in the Indian Ocean

	N(10° S)	S(20° S)	E
0-300 m			
C (temperature, °C)	18.57	20.61	20.42
C (salinity, ‰)	34.85	35.39	34.43
C (tritium, TU)	2.4	2.5	3.0
Area (10^8 m^2)	20.7	19.8	2.9
Transport (10^6 m^3 s^{-1})	−2.4	−2.6	+5.1
Error (10^6 m^3 s^{-1})	±0.1	±0.4	±0.4
0-100 m			
C (temperature, °C)	25.66	24.30	25.70
C (salinity, ‰)	34.80	35.20	34.20
C (tritium, TU)	3.5	3.6	3.8
Area (10^8 m^2)	6.9	6.6	1.0
Transport (10^6 m^3 s^{-1})	±1.7	−3.6	+2.0
Error (10^6 m^3 s^{-1})	±0.7	±0.2	±0.5

Positive (negative) transports indicate a net flow into (out of) the box across that boundary.

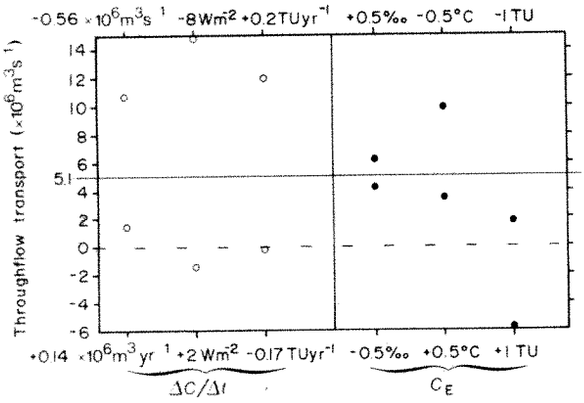

Fig. 3 Comparison of the box model result of 5.1×10^6 m^3 s^{-1} throughflow to variations in: ○, air-sea flux parameters ($\Delta C/\Delta t$) ($\Delta C/\Delta t$ is varied for: freshwater, heat, and tritium input); and ●, concentrations along the eastern boundary of the box (C_E) (C_E is varied for salinity, temperature, and tritium).

results of that regression are also included in Table 1. The net transports across both 10° S ($1.7 \pm 0.7 \times 10^6$ m^3 s^{-1} into the box) and 20° S ($-3.6 \pm 0.2 \times 10^6$ m^3 s^{-1} out of the box) are southwards; this is consistent with theories of a surface Ekman poleward flow. There is a net transport into the box across the eastern boundary of $2.0 \pm 0.5 \times 10^6$ m^3 s^{-1}. This calculation, which gives only 2×10^6 m^3 s^{-1} for the throughflow (0–100 m), shows that more than half of the transport calculated for the box 0–300 m is below the mixed layer.

Figure 3 shows the sensitivity of the throughflow transport to uncertainties which are at least several times the errors in the data. At either extreme in the balance between the tritium decay rate (-0.17 TU yr^{-1}) and deposition rate[12] (0.20 TU yr^{-1}), the effect is to decrease to nearly zero or double the throughflow transport. The uncertainties in the freshwater and heat air-sea fluxes are unknown, although it is unlikely that the directions of the fluxes are unknown. A fourfold increase in these fluxes results in more than a doubling of the throughflow transport. Varying concentrations along the eastern (Fig. 3), northern and southern boundaries of the box result in net positive throughflows, except when C_E and C_N for tritium are increased by 30% (1 TU). These sensitivity tests always result in a net northward transport across 10° S; this is consistent with observations of a northwestward current at the northern tip of Madagascar (F. Schott, personal communication). The tests also result in a positive correlation between throughflow and southwards transport across 20° S; this is consistent with the assertion by Piola and Gordon[2] that the upper layer throughflow transport must be balanced by southwards flow across 35° S in the Indian Ocean.

A throughflow transport exceeding 10×10^6 m^3 s^{-1} is unlikely. Godfrey and Golding[5] pointed out this high a transport would require large upper-layer velocities >1 m s^{-1} in some of the Indonesian passages; these have not been observed. In addition, the throughflow would then amount to 30–50% of the total volume transport for the SEC which is $30\text{–}40 \times 10^6$ m^3 s^{-1} (F. Schott, personal communication). Because of the high tritium intrusion, it is also unlikely that there is no net throughflow transport or even that it is reversed. When the regression was run for three equations and three unknowns, successive omission of salinity, heat and tritium gave throughflows respectively of 2.0, 13.4 and 10.9×10^6 m^3 s^{-1}; direction of the transports across the other two boundaries remained unchanged. Salinity has the most redundancy, that is freshwater, heat and tritium are the three most linearly independent parameters. These sensitivity analyses suggest that the box model calculation of 5×10^6 m^3 s^{-1} for the throughflow transport is probably good to within ±50%.

The tritium data show a direct link between the Pacific and Indian oceans. The interannual variability in the throughflow could have direct implications for climate because it is coincident with a warm pool of 28 °C or higher[14]. The warm pool is found to extend from the western Pacific through to the Indian Ocean. The unique relationship of the Southern Oscillation to sea-surface temperature (SST) in the region extending from the warm pool southwards to northern Australia[24,25] has been shown to have a high correlation[26]. In addition, SSTs in that region have been shown to have an influence on the monsoon[27,28], because the largest region of deep atmospheric convection occurs over the warm pool. Changes in intensity and location of this convection zone are related to variability in both the global atmospheric circulation and the monsoon, and are probably also influenced by changes in the underlying warm, low-salinity throughflow water.

I thank Gary Meyers for suggesting the examination of the tracer data in relation to the throughflow problem; H. Gote Ostlund for the tritium data; Fritz Schott for suggesting the use of the air-sea flux terms; James Mattson, Julian McCreary, Claes Rooth for many useful comments; and the NSF OCE7822120 and OCE8024904 for support.

Importance of thrust faulting in the tectonic development of northern Victoria Land, Antarctica

G. M. Gibson

T. O. Wright

Earth Science Division, National Science Foundation, Washington, DC 20550, USA

The present configuration of Wilson Group, Bowers Supergroup and Robertson Bay Group in northern Victoria Land (Fig. 1) has been attributed to high-angle block-faulting[1–3] or more recently[4] to major strike-slip faulting along the Lanterman and Leap Year Fault zones. In this latter interpretation[4], adjacent units have allochthonous relationships and constitute separate geological terranes. We offer additional support for the concept of allochthonous terranes in northern Victoria Land but suggest here an alternative

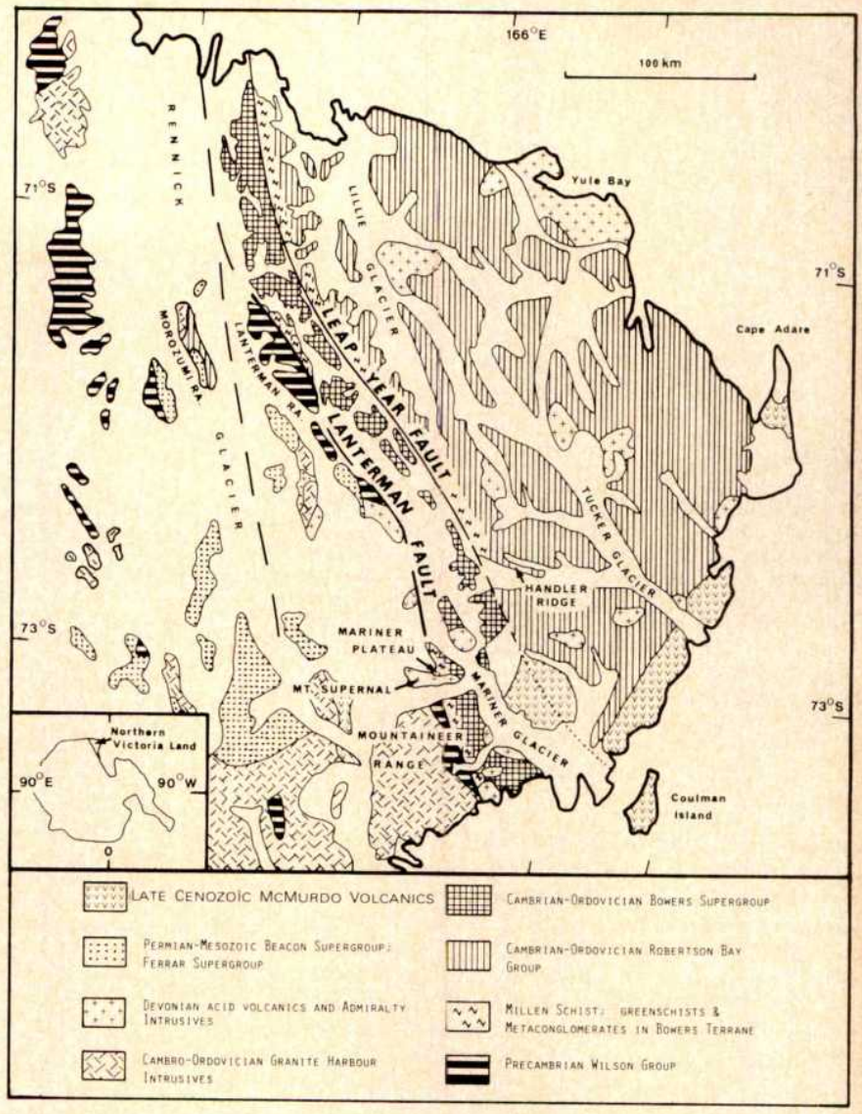

Fig. 1 Geological map of northern Victoria Land (compiled from data in refs 1, 3, 4, 12).

model to explain terrane juxtapositions. Our model emphasizes the role of thrust tectonics and implies severe structural telescoping of entire terranes with significant loss of intervening crust. We further suggest that this occurred during the Lower Palaeozoic Ross Orogeny in response to the collision of Antarctica with a westwardly directed eastern continental block. This requires that the northern Victoria Land segment of Gondwana was a zone of major plate convergence throughout the Cambrian–early Ordovician period.

The Wilson terrane contains mainly (?Precambrian) amphibolite facies gneisses intruded by Lower Palaeozoic S-type granitoids (Granite Harbour Intrusives[5,6]). These gneisses have undergone four phases of deformation[7–9], the first two of which were accompanied by intense flattening and development of boudinage. A conspicuous stretching lineation defined by elongated mineral aggregates is widespread throught the Lanterman Range and also occurs in Wilson Group gneisses immediately west of the Bowers Supergroup in the Mountaineer Range. In the Lanterman Range, this lineation originated during the second phase of deformation and everywhere plunges steeply down-dip within the north-west-trending regional foliation (Fig. 2*a*). The third and fourth phases of deformation in the Lanterman Range were associated with retrogressive metamorphism to the greenschist facies and the widespread development of crenulation structures[7,8].

The Bowers terrane contains a Cambrian–early Ordovician regressive sequence[2,10] which has at its base the Sledgers Group. Sledgers Group comprises two mutually interdigitating units[10]: the Molar Formation composed of marine volcanogenic sediments and the Glasgow Volcanics consisting of pillow lavas, basaltic and andesitic breccias, and subordinate dacite–rhyolite[4,10]. Basic rocks within the Glasgow Volcanics are interpreted [4] as primitive island arc tholeiites.

Overlying[2,10] the Sledgers Group are the non-volcanogenic, shallow or marginal marine, Mariner Group and the non-marine Leap Year Group.

Two other units are also included here in the Bowers terrane; the Lanterman and Husky Conglomerates, both of which occur only in the Lanterman Range along the western margin of the terrane. They are characterized[7] by intensely flattened pebbles and provide important clues about the nature of tectonism along the contact between the Bowers and Wilson terranes. Other conglomerates with severely flattened, or sometimes even stretched, pebbles occur in the Molar Formation immediately south of the Meander Glacier in the Mountaineer Range[3,11,12].

The Bowers Supergroup was mainly metamorphosed under prehnite–pumpellyite or pumpellyite–actinolite facies conditions[13] and generally underwent folding about gently plunging, north-west-trending axes[13,14]. Multiply-deformed greenschist facies rocks are restricted[7,11,12] to a narrow (2–4 km) belt immediately east of the contact with Wilson Group (Fig. 1). Highly strained conglomerates in this belt exhibit characteristics of both flattening and constrictional deformation[7,11]. Fold axes within this belt also show extremely variable plunge, sometimes steepening quite markedly over short distances, although they always maintain a constant north-west orientation within their axial surfaces (Figs 2*b*, *d*–*f*). This suggests non-cylindrical folding, possibly even the presence of sheath folds. Where

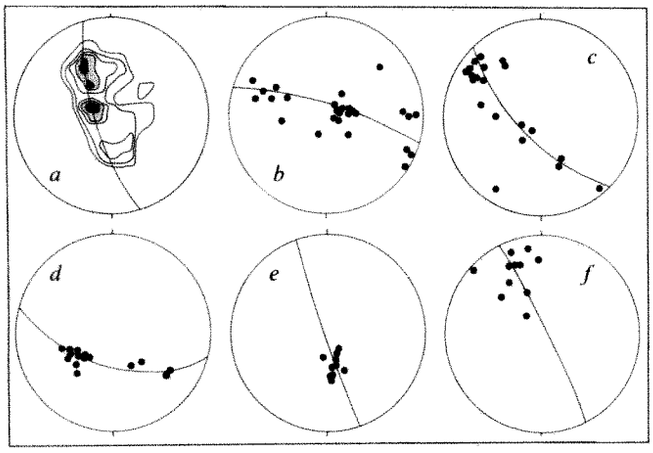

Fig. 2 Equal area stereographic projections of regional structures in the different terranes of northern Victoria Land. Solid lines, dominant schistosity or cleavage; dots, lineations and fold axes except in *a* which includes 112 stretching lineations from Wilson Group gneisses in the Lanterman Range. Contour interval is 1%, 3%, 6%, 9% and 12% per 1% area. *b*, Bowers terrane immediately east of Wilson terrane in the Lanterman Range. *c*, Robertson Bay terrane, data from ref. 14. *d–f*, Bowers terrane; *d*, belt of greenschist facies rocks immediately east of contact with Wilson terrane; *e*, greenschist facies rocks on the Mariner Plateau; *f*, virtually unmetamorphosed Bowers supergroup from area in the lower Mariner glacier. Shading accentuates contour interval.

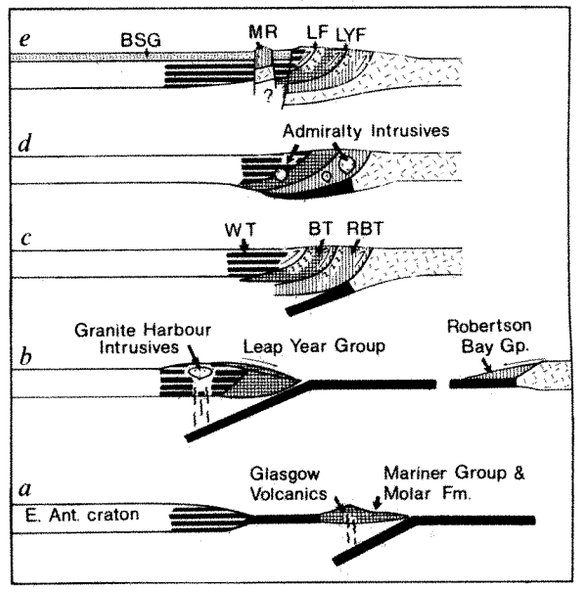

Fig. 3 Tectonic model for northern Victoria Land. *a*, Middle–late Cambrian: development of Glasgow Volcanic arc concomitant with the deposition of Molar Formation and the Mariner Group in a forearc basin. To the east, Robertson Bay Group is deposited as a clastic wedge with continental provenance. *b*, Late Cambrian–early Ordovician: following accretion of the Glasgow Volcanic arc onto the Gondwana continental margin, the centre of magmatic activity migrated westward leading to the intrusion of the Granite Harbour Intrusives and the penecontemporaneous deposition of Leap Year Group (following uplift and erosion of granites). *c*, Ordovician: Ross Orogeny with substantial crustal thickening and underthrusting of one terrane beneath the next. Deformation and regional metamorphism with the Bowers Supergroup; retrogressive metamorphism within the Wilson terrane. *d*, Devonian–Carboniferous: intrusion of Admiralty Intrusives. *e*, Post-Ferrar Supergroup Rennick block faulting[1]. Differential uplift and erosion in the Morozumi Range remove the overlying Wilson and Bowers Supergroup rocks to create a tectonic window in which Robertson Bay Group sediments are exposed. Abbreviations: BSG, Beacon Supergroup; BT, Bowers Terrane; LF, Lanterman Fault; LYF, Leap Year Fault; MR, Morozumi Range; RBT, Robertson Bay Terrane; WT, Wilson Terrane.

asymmetrical folds have been observed[9,11], they generally indicate tectonic transport to the north-east, at right angles to the structural trend of the Bowers terrane. Since the Leap Year Group contains only one-fold generation, and locally[10,11] rests unconformably upon Sledgers Group (without intervening Mariner Group), some deformation of Bowers rocks evidently occurred prior to deposition of the Leap Year Group.

The Robertson Bay terrane contains mainly marine sediments of continental provenance[1,2,15,16]. Along with Bowers Supergroup, these rocks were intruded by the Devonian–early Carboniferous Admiralty Intrusives which possess I-type characteristics[3,17,18]. Although formerly considered to be Precambrian or possibly Cambrian in age, the recent discovery[19,20] of Ordovician fossils in the Robertson Bay Group at Handler Ridge makes a Cambrian–early Ordovician age more likely.

The structural relations of the Robertson Bay Group and Bowers Supergroup are strikingly similar. To the east, weakly metamorphosed[21,22] Robertson Bay Group contains[14,21,23] a single phase of upright, variably plunging folds which trend north-west (Fig. 2*c*), whereas close to the Leap Year Fault there is a belt of multiply deformed greenschist facies rocks (Millen schists)[23,24]. These schists occupy a structural position comparable with that of the greenschist facies rocks along the western margin of the Bowers terrane. Both belts lie immediately east of major tectonic boundaries: the Leap Year and Lanterman Faults respectively. This implies a genetic as well as spatial relationship between the faults and greenschist facies rocks.

The Leap Year Fault has been traced[3,25,26] across virtually the entire length of northern Victoria Land. Recent mapping[11] suggests the Lanterman Fault (type locality[14,25] in the Lanterman Range) extends southwards into the Mountaineer Range. In both areas, Wilson Group rocks are thrust[7,11] against the Bowers terrane (Fig. 1). Moreover, on the Mariner Plateau (Fig. 1), the Lanterman Fault is cut by one of the Devonian Admirality Intrusives (Mt Supernal Granite). Mylonites in this same region partly recrystallized during the associated contact metamorphism. Because the country rocks had also undergone regional metamorphism and deformation before granite emplacement[11], we infer that both the thrust faulting and the regional deformation and metamorphism are manifestations of a pre-Devonian event: the Lower Palaeozoic Ross Orogeny.

The Lanterman and Leap Year faults both possess features compatible with major strike-slip faults. They have straight traces, dip steeply and are marked by wide crush zones, up to 500 m wide in the case of the Leap Year Fault[3]. These few features aside, there is no additional evidence for strike-slip faulting. Both faults are better interpreted as major thrusts. Along the entire length of the Lanterman Fault in both the Lanterman and Mountaineer ranges, Wilson Group amphibolite facies gneisses are consistently juxtaposed against lower grade Bowers Supergroup rocks. The faulted contact between these two units, clearly visible north of Mitten Spur in the Lanterman Range, dips steeply south-west. Slickensides along this fault indicate that movement was directed towards the north-east[7]. Parallel, and presumably related, thrust faults occur[9,12] within the Mountaineer Metamorphics west of the Lanterman Fault. They too bring higher-grade rocks over lower-grade ones. A syn-metamorphic thrust fault has also been reported[23,24] in the Millen Range just east of the Leap Year Fault.

In the western Lanterman Range, Lower Ordovician Granite Harbour Intrusives are thrust over Permian tillites and slate[8]. Late-stage reverse faults also affect the deformed conglomerates in the eastern Lanterman Range[7]. Some thrusting clearly postdates the Ross Orogeny and may represent the reactivation of pre-existing structural discontinuities. Reorientation and/or modification of the earlier thrust faults seems likely.

Based on our interpretation that the Lanterman and Leap Year faults are major thrust boundaries, we present an alternative tectonic model for northern Victoria Land (Fig. 3). It is at variance with earlier ideas[3] of a Bowers graben and precludes significant strike-slip faulting[4] along the Lanterman and Leap Year faults during the early Palaeozoic. In our model, the present disposition of rock types is primarily the result of massive telescoping along the Lanterman and Leap Year faults with one terrane underplated beneath the next. Elements of a primitive island arc (Sledgers Group) were accreted onto the Gondwana margin before a continent-continent collision with significant loss of oceanic crust. The Robertson Bay Group represents an accretionary wedge brought into juxtaposition with the Bowers Supergroup from the east following closure of the intervening ocean. Our model not only implies allochthonous relationships between adjacent terranes but substantial crustal thickening beneath the Transantarctic Mountains during the Ross Orogeny.

Other attributes of our model include:

(1) It provides different source areas for the compositionally dissimilar Sledgers and Robertson Bay Group sediments.

(2) Structural telescoping and significant underthrusting of Bowers Supergroup below the Wilson terrane brought island-arc tholeiites (Glasgow Volcanics) within 6 km of the calc-alkaline Granite Harbour Intrusives and removes earlier objections[4] that the Bowers terrane is too narrow for a typical arc

(3) Fold vergence, the common structural trend of all three terranes, and the down-dip stretching lineation in Wilson Group gneisses are consistent with thrusting directed towards the north-east.

(4) Thrusting immediately following regional metamorphism and/or cessation of subduction emplaced hot Wilson Group rocks over the Bowers terrane. This produced higher temperatures (greenschist facies metamorphism) and the intense flattening observed in rocks along the western margin of the Bowers terrane. Similarly, the Millen schists east of the Leap Year Fault resulted from the thrusting of Bowers rocks over the Robertson Bay terrane.

(5) The Robertson Bay and Bowers terranes are underlain by oceanic crust which provided possible source rocks for the Admiralty I-type granites.

A weakness in our model is the lack of an appropriate suture zone between the Bowers and Robertson Bay terranes. The Leap Year Fault is one possible choice but no fragment of a subduction complex, mélange, blueschist terrane or ophiolite belt is preserved along its trace. An additional problem is the absence of continental crust east of the Robertson Bay terrane, although rocks of suitable age have recently been reported[27] on Surgeon Island in Yule Bay.

We thank thank the Bundesanstalt für Geowissenschaften und Rohstoffe for the opportunity to join GANOVEX III and for the invitation to participate in the 1984 NVL workshop in Hannover where many of these ideas were discussed.

Diagenesis of sediments beneath the Ross Ice Shelf and their sedimentary history

R. Raiswell

Department of Earth Sciences, University of Leeds, Leeds LS2 9JT, UK

M. Md. Tan

School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK

Micropalaeontological studies of sediment cores collected from beneath the Ross Ice Shelf, Antarctica, give conflicting stratigraphical interpretations. The diatom flora initially indicated an *in situ* succession of later middle Miocene age[1,2], which was supported by the occurrence of benthic foraminifera[3]. However, subsequent diatom analyses record the presence of flora with mixed ages (mostly Miocene but also Pliocene and Pleistocene) throughout both of the two lithological units present in the cores. These flora are taken to indicate repeated reworking, which most recently occurred no earlier than the late Pleistocene[4]. These contrasting views have since been re-affirmed[5,6]. Our studies of sediment geochemistry show self-consistent patterns in organic carbon, organic nitrogen and sulphur diagenesis which suggest a Recent, *in situ* origin, at least for the upper unit.

The 47 Ross Ice Shelf Project (RISP) cores collected at site J9 (82°22′ S, 168°28′ W) in the 1977-78 field season have lengths ranging from 15 to 122 cm and contain an upper light olive-grey unit (9-30 cm thick) at the base of which is a thin (<1 cm) brown-orange, iron-rich layer, providing a sharp colour contrast with the darker olive-grey lower unit (>86 cm) thick[3]. Both upper and lower units consist of pebble-granule diatomaceous mud, soft and sloppy in the upper unit but firm and compact in the lower. Quartz, feldspars, clays and diatoms generally comprise >80% of the sediments and the only discernible mineralogical difference between the two units is the presence of minor chlorite and vermiculite in the upper unit[7].

Siliceous diatoms are the most abundant microflora and occur uniformly throughout the upper and lower units Calcareous benthic foraminifera also occur in the lower unit but are absent from the upper unit[1-4]. There are two conflicting views as to the age of the microflora. One view is that the diatoms are well-preserved, except in the upper unit, and indicate a middle Miocene age with the foraminifera in the lower unit being slightly older (early to middle Miocene). This view is consistent with the presence of an *in situ* middle Miocene succession, with the upper lithological unit representing an alteration product of the underlying sediment[2,7]. The alternative view crucially depends on the recognition of minor proportions of smaller, more delicate and poorly preserved Pliocene to late Pleistocene diatoms, which have been recorded amongst the predominantly middle Miocene flora throughout both units. The presence of flora with mixed ages is taken to indicate subglacial reworking, probably in the late Pleistocene (21,000-17,000 yr BP) and possibly also earlier[6]. Thus, there are controversial questions concerning the timing of deposition and the extent of reworking and alteration in the RISP cores, which are of importance in establishing the history of the West Antarctica Ice Sheet.

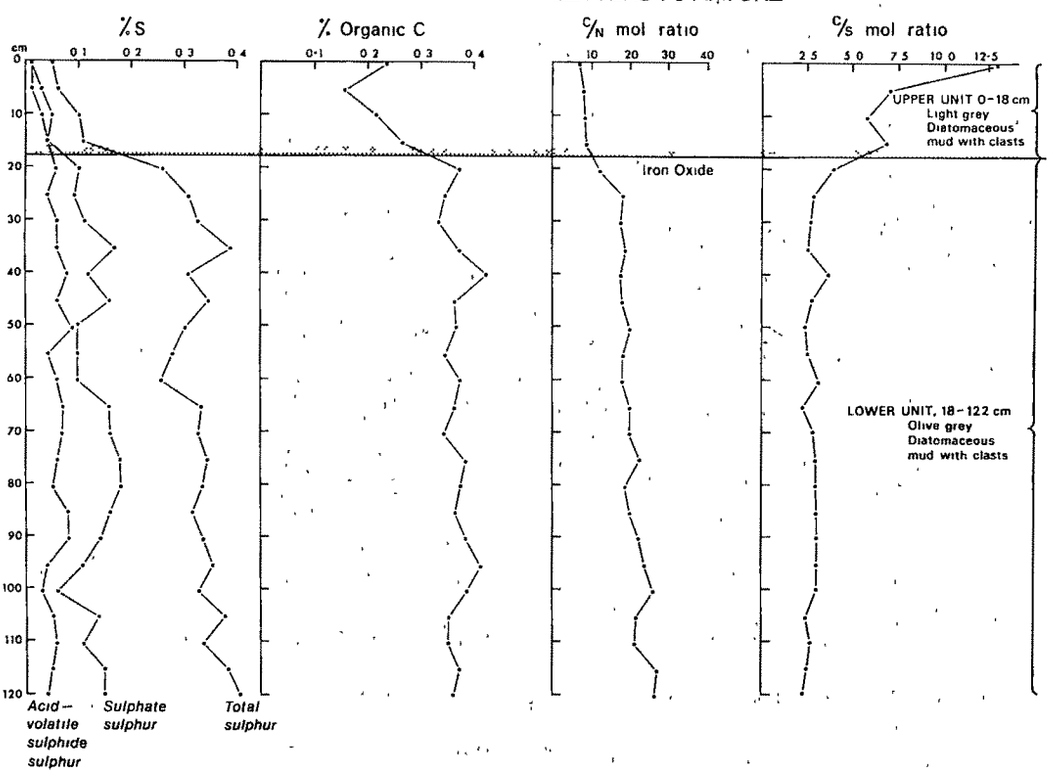

Fig. 1 Depth trends in S species, organic C and the C/S and C/N mole ratios in RISP core no. 12.

A study of chemical diagenesis was undertaken to clarify aspects of the sedimentary history. The longest RISP core, no. 12, was selected to define chemical gradients most accurately. Excess water was allowed to drain away before cores were frozen for transportation[3]. However, samples were received in a dry, unfrozen state and chemical effects may arise from sulphide oxidation and contamination by salts from dried porewater: the latter effect is small. This core provided 25 samples located at 5-cm intervals over 122 cm. These were crushed to <90 μm and analysed for organic C, organic N (by Hewlett Packard CHN analyser), acid-volatile sulphides and gravimetrically for total S and sulphate-S. Organic C and organic N determinations were made at 600 °C to minimize breakdown of carbonates[8]. Both results agreed closely with determinations at 1,200 °C following treatment with dilute HCl which removes calcareous material, exchangeable ammonium and also some fixed ammonium[9]. Organic C analyses in both cases also agreed closely with an alternative combustion method[10] and are consistent with those published elsewhere[11].

Water contents were measured before sampling (G. S. Boulton, personal communication) and decreased from 22.7% near the top of the core to 16.1% at the base. For porewaters of average seawater composition, marine sulphate could not exceed 0.01% S and most sulphate must arise from sulphide oxidation. Total S is accordingly treated as sulphide-S.

The depth profiles demonstrate the following differences in the amounts and compositions of the phases participating in diagenesis (Fig. 1). (1) Organic C (0.16–0.27%) and total S (0.05–0.11%) contents are both smaller in the upper unit than in the lower unit (organic C 0.34–0.42%, total S 0.26–0.41%). (2) The total sulphur, C/S and C/N ratios change progressively with depth through the upper unit and across the boundary, reaching near-constant values at depths >25 cm.

These features arise as a result of microbiological diagenesis of sedimentary organic matter, principally by sulphate reduction.

$$2CH_2O + SO_4^{2-} \rightarrow H_2S + 2HCO_3^-$$

Bacterial sulphate reduction occurs only in the absence of oxygen but such conditions are common in marine sediments, which then allow anaerobic sulphate-reducing bacteria to oxidize metabolizable organic matter to dissolved carbonate species and so produce H_2S by the reduction of seawater sulphate. The H_2S reacts with detrital iron minerals to give black, acid-volatile iron sulphides which are then slowly converted to pyrite. Sulphide contents thus increase with depth (from low surface values) in Recent sediments deposited in conditions where depth and time of burial are related. Such gradients have been described in many different depositional environments[12–14]. Furthermore, in sediments deposited under an oxygenated water column, pyrite formation is apparently limited by the fraction of organic matter which can be metabolized. Thus continuing sulphate reduction is accompanied by a decreasing ratio of organic C to sulphide-S(C/S), which typically reaches a constant value at depths of <2 m, when metabolizable organic C is mostly exhausted[13–15]. Total organic C is a poor measure of metabolizable organic C in a sediment, since the latter depends on the extent of preservation in the water column and is also affected by benthic activity and terrestrial contributions[16]. However, most organic N is present in proteins which undergo rapid preferential destruction such that the C/N mole ratios of organic matter reach constant values, typically of about 15 or more, after only 1–2 m burial in Recent sediments[17,18].

Recent sediments deposited in a depth–time sequence thus show near-surface gradients of an increasing sulphide content, increasing C/N ratio and a decreasing C/S ratio. These gradients can provide a useful signature of age. The observed gradients in total S, C/N and C/S ratios in the RISP sediments are similar to those observed in Recent sediments and are also internally consistent, in that the addition of sulphide (gradients in total S and C/S) corresponds to a decrease in the metabolizable fraction of the organic matter (as indicated by the C/N gradient). A Recent origin, at least for the upper unit, is also indicated by the C/N ratios, which are close to the range in diatoms and plankton (5–6.6)[17]. Contributions from fixed ammonium may cause these values to be low, although most fixed ammonium is associated with illitic clays[19] which rarely exceed 30% of similar Ross Sea Miocene sediments[20]. The near-surface RISP samples have C/N values which clearly indicate that the sediment was mixed with fresh organic material on deposition. Such material typically survives near-surface anaerobic microbiological decay for between a few hundred to a few thousand years, as indicated by the time needed to reach uniform C/N and C/S values[13–17]. Diagenetic nitrogen loss is slower in oxic sediments (where it does not occur concomitantly with pyrite formation) but is still completed within <120,000 yr (ref. 19), except where

rates of bacterial metabolism may be limited by the diffusion of electron acceptors through a large thickness of sediment[21]. Thus, although the absence of benthic activity[22] and low metabolic rates in the water column[23] may diminish the decay of metabolizable nitrogenous material, it seems certain that the upper unit contains organic matter of Recent (or at the very oldest, late Pleistocene) origin. Radiocarbon ages support a Recent origin[4]. Recycled spores and pollen have been identified in RISP sediments[2,11], but the C/N ratios of plant material (13–26) are much larger than the C/N values in the upper unit, and recycled terrestrial material cannot be the main organic matter source.

The diagenetic gradients indicate that deposition of the upper unit has occurred postglacially, with fresh organic matter being incorporated during the reworking of older sediments. Thus the geochemical data are consistent with the occurrence of a reworking event which mixed Pliocene and Pleistocene fauna with the Miocene forms[4], but not with the existence of an *in situ* Miocene succession[1,2]. No reworking of the upper unit has occurred following deposition at the present site, otherwise no depositional or diagenetic variations would occur. In this respect, we agree with the conclusions based on ^{10}Be measurements, although these imply a pre-Quaternary origin at the latest for the upper unit[24]. Such a prolonged period of non-deposition is incompatible with the existence of reduced S species, and nitrogenous organic matter, at the sediment–water interface. Comparatively large ^{10}Be ages may result from diminished rates of ^{10}Be deposition at high latitudes and in the presence of an ice cover[25].

As the two units are so similar in detrital mineralogy, their main chemical differences arise as a result of alteration by *in situ* diagenesis which differs only in degree and not in direction. The extent of alteration by diagenetic sulphate reduction is mainly controlled by metabolizable organic matter concentrations and a fundamental difference between the two units is the lower organic C content of the upper unit, even though the diagenetic loss of organic C is not yet completed here. Hence, the lighter colour of the upper unit is probably due to a smaller content of black, iron monosulphides arising from both a lower initial organic C content and unfinished sulphate reduction. Complete diagenetic alteration of the upper unit would result in a sediment with less organic C and S than the lower unit, although the progressive C/N and C/S trends would suggest that the two units would ultimately be very similar in these respects.

The total S, C/S and C/N trends appear to pass through the iron oxide layer (at 18-cm depth) without major perturbation, but by 25 cm have closely approached the values at greater depths. The depth at which diagenesis is mostly complete thus lies only a little below the iron oxide layer and hence there are no unequivocal signals of depth–age relationships in the lower unit. However, the small but irregular trends of increasing total S and C/N values would be consistent with continuity of diagenesis through the iron oxide layer, and hence with a post-late Pleistocene origin for the whole core.

The iron-stained layer between the two units is a major chemical discontinuity whose temporal significance is unclear. No samples at this depth were analysed, but the small kink in the C/S ratio at 15–16 cm suggests a possible loss of S which, together with the presence of iron oxides, implies a discontinuity in sedimentation which allowed the oxidation of sulphidic sediments by exposure to oxygenated seawater. The oxidation of sulphides may proceed quite rapidly under these circumstances and numerical models for the oxidation of sulphidic sediments by the diffusive penetration of dissolved oxygen into the RISP sediments indicate that a 1-cm oxide layer could be produced in as little as 100 yr.

The diagenetic chemistry clearly demonstrates that the RISP sequence is not wholly Miocene and that the upper unit is probably of Recent origin. Unfortunately, there are no clear indications as to the age of the lower unit. Our observations can be reconciled with the presence of Miocene, also Pliocene and Pleistocene, fauna if the upper unit was formed by reworked material (similar to that in the lower unit) which was redeposited following suspension in the water column (which would allow an autochthonous organic matter contribution). There are no chemical features which are inconsistent with a post late-Pleistocene origin for the whole core.

We thank the RISP support group, especially John Clough, the Office of Polar Programmes and Dr G. S. Boulton.

Late-Quaternary climatic change on the American North Pacific Coast

C. J. Heusser*, L. E. Heusser† & D. M. Peteet‡

Temporal changes in solar radiation caused by variations in the Earth's orbit figure prominently in current Quaternary climate theory[1–4]. Experimental design of atmospheric circulation models emphasizes the importance of solar radiation in the heating of interglacial land and ocean surfaces at different seasons of the year, whereby monsoon-type circulation—seasonal shifting of regional cyclonic and anticyclonic centres—develops, while during glacial ages, seasonality is greatly modified by the influence of ice sheets[5–7]. We investigated the late-Quaternary climate of the North Pacific, where according to modelling, solar radiation in the early Holocene at the time of the summer solstice is high and in the late Holocene is relatively low. We compared quantitative temperature and precipitation estimates from southern Alaska, obtained by application of transfer functions to fossil pollen records, with estimates from western Washington[8] and southern British Columbia[9]. Data extending over >10,000 years show a broadly consistent pattern of climatic change in general agreement with predicted variations in solar radiation and their effect on atmospheric circulation and seasonal duration of pressure systems over the North Pacific Ocean. In the early Holocene, as monsoon-type circulation became established with melting of glaciers, the subtropical North Pacific anticyclone annually regulated climate for a longer period at higher latitudes than at present, so that warmth and dryness (high summer radiation) increased in southern Alaska. The Aleutian low-pressure centre, locus of cyclonic storm activity, intensified during the late Holocene, resulting in colder and more humid coastal climate (low summer radiation) over much of the year and increased frequency of glacier growth in the cordillera.

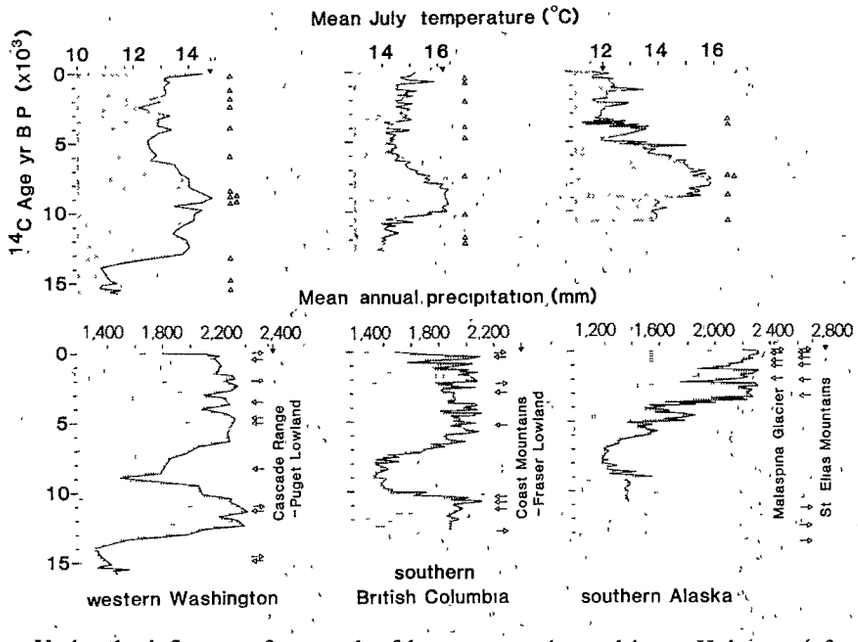

Fig. 1 Late-Quaternary mean July temperature and annual precipitation estimated by use of transfer functions for sectors of North America located in western Washington (47° 49′ N, 124° 12′ W)[8], southern British Columbia (49° 15′ N, 122° 20′ W)[9], and southern Alaska (60° 01′ N, 141° 57′ W). Data are drawn to a uniform time scale with chronology indicated by radiocarbon ages (△) and assuming constant sedimentation rates between ages. Markers on temperature and precipitation scales are modern means. Arrows pointing left next to precipitation curves signify times of glacier advance, whereas retreat is indicated by arrows pointing right; vertical lines between arrows indicate extended intervals of glacier activity.

Under the influence of a trough of low pressure located in the Aleutian/Gulf of Alaska region, climate today along the American north-west coast is mostly stormy, cold and rainy[10]. In summer, as the subtropical anticyclone develops over the North Pacific Ocean, the Aleutian low is weakened and displaced northwestward by the build up of high pressure. Some weeks of relatively stable conditions ensue in the western conterminous United States and southwestern Canada, providing a contrast with the weather during the colder part of the year. Although summer months in southern Alaska and northern coastal British Columbia are driest, influenced by the seasonal pressure change, cyclonic storms, accompanied by heavy precipitation and cloudiness, continue to strike this sector of the coast.

Seasonal duration and extent of pressure systems over the North Pacific were variable in the late Quaternary, as implied by quantified mean July temperature and annual precipitation estimates for three geographic areas (Fig. 1). Data from southern Alaska serve for comparison with data from the Olympic Peninsula of western Washington[8] and the Coast Mountains of southern British Columbia[9]. All three data sets were generated by two independent regression equations[8] that relate modern composition of pollen in surface samples from the Pacific coastal forest and tundra regions to recorded temperature and precipitation values at sites between the Aleutian Islands and California. Applied to radiocarbon-dated fossil pollen records in the three areas, the equations yield estimates of late-Quaternary climatic parameters. Transfer functions used were applied within the limits of the calibration data set.

Southern Alaska data (Fig. 1) are derived from fossil pollen contained in two sections of a muskeg located near Munday Creek on the Gulf of Alaska, ~15 km north-west of Icy Cape in the Malaspina Glacier district. One section extends to ~9,000 yr BP[11] whereas the other reaches beyond to 10,820 yr BP[12]. Mean July temperature is near 14 °C at the end of the Pleistocene (10,000 yr BP) and in the early Holocene, reaching a maximum close to 16 °C at ~8,000 yr BP and then decreasing to 12 °C at ~5,000 yr BP, with fluctuations around this value until the present. Annual precipitation, just under 1,400 mm at the beginning of the record, reached a minimum near 1,200 mm, coinciding with the temperature maximum at ~8,000 yr BP, and thereafter increased to almost twice as much during the past four millennia, while temperature fell to its lowest level of the entire time span.

Temperature and precipitation trends expressed by the curves represent a pattern, repeated to the south in British Columbia and Washington (Fig. 1). All sites show early Holocene temperature maxima and precipitation minima, whereas in the late Holocene (after 5,000 yr BP), as in the late Pleistocene, higher precipitation is coincident with lower temperature. Increased warmth and dryness during the early Holocene suggest extended dominance by the subtropical Pacific anticyclone; conversely, before and after this interval, when precipitation amounts are higher and temperature values lower, polar Pacific cyclones became effective in generating storms that increased in frequency over a greater part of the year. Changes associated with the centres of atmospheric pressure were influenced to a great extent by land–ocean temperature contrasts, latitudinal temperature gradients and topography. Changes follow closely predictive general circulation models in which monsoon-type climate is related to variations in seasonal solar radiation intensity[5–7].

Storm activity, implied by the fossil evidence, was most intense in the late Holocene in southern Alaska, where precipitation increased by some 1,200 mm and temperature fell ~4 °C. Particularly wet climate effecting generation of the muskeg studied near Icy Cape is indicated by an unusually high deposition rate (42 mm yr^{-1}, assuming no compaction) for 150 cm of unhumified peat formed between 3,860 and 3,500 yr ago; before this, under a warmer, drier climate between 9,000 and 7,700 yr ago, rate of deposition of 25 cm of highly humified peat was much lower (2 mm yr^{-1}). Rapid peat deposition close to 3,500 yr ago has been found elsewhere in southern Alaska[13].

This pronounced climate change occurred at the time of the Neoglaciation, during which colder wetter conditions, giving rise to excessive snowfall in the lofty St Elias Mountains, caused glacier regeneration (Fig. 1) between 3,300 and 2,100 yr ago, 1,250 and 1,030 yr ago and in recent centuries, after an extended interval of early Holocene recession[14–18]. During the Neoglaciation, ice flow from the St Elias Mountains contributed to the formation of the huge piedmont lobe of Malaspina Glacier, which spread across the coastal lowland and continental shelf to the Pacific. Episodes of ice advance in the Malaspina Glacier district occurred over the past two millennia, with maxima dated between 1,600–1,200 and 830–560 yr ago and in the past few centuries[19–23].

Malaspina Glacier, covering some 2,200 km^2, rests mostly below sea level[24] along a part of the Gulf of Alaska coast that, under the warmer, drier climate of the early Holocene, was probably an embayment. Located between the eastern end of the Robinson Mountains at Icy Bay and the Deception Hills at the mouth of the Alsek River, the embayment extended along >200 km of coastline, including present-day Icy and Yakutat Bays, before the Neoglaciation. Higher temperature and lower precipitation estimates make it unlikely that mass balance of Malaspina Glacier in its present lobate form could have been maintained in the early Holocene.

Greater frequency of storms passing across southern British Columbia and Washington over the past six or seven millennia is reflected by the estimates of increased precipitation in this part of the coast (Fig. 1). The increase, while temperature steadily decreased, inaugurated late Holocene glacial episodes at ~5,000 yr ago[25-31]. During the early Holocene, except for isolated instances of minor glacial advance in the Cascade Range[32-34], glaciers were inactive. Climate, under control of the subtropical anticyclone, was apparently too warm and dry for glacier growth. In the late Pleistocene (15,000–10,000 yr ago), a major advance occurred in the Puget Lowland in a cold, dry climate ~14,500 yr ago[35], followed under wetter but less cold conditions by minor advances in the Fraser Lowland and North Cascades close to 11,000 yr ago[36-38] and in the Coast Mountains ~10,500 yr ago[39]. Late Pleistocene glaciation of the Puget Lowland has been attributed to northward movement of storm tracks, causing heavy snowfall in the glacier source region in the Coast Mountains of British Columbia, coincident with decay of the Laurentide ice sheet[40]

In the long-term, late-Quaternary climate fluctuations along the American north-west coast, keyed to shifting dominance of atmospheric pressure cells over the North Pacific, are outlined by the pattern of temperature and precipitation estimates. They conform with temporal changes in seasonal radiation intensity predicted by experimental modelling[5-7], previously brought out by fossil pollen studies in north-west Canada[41]. In the absence of tighter radiocarbon-dated time control over extended intervals in the records, assessment of short-term fluctuations of the estimates (of the order of centuries) is not justified. Rates of response to climate change, as well as speed of migration northward following deglaciation of the British Columbia and Alaskan coasts, by plant species used in the equations, for example, are variables that must enter into the timing of events. These may be significant, but further dating and replication are required to define them.

We thank S. C. Porter for unpublished data on glacier fluctuations in the Malaspina Glacier district and C. A. Sancetta, D H. Rind and W. F Ruddiman for critical comments on the manuscript. Final version of the letter was completed while C.J.H and L.E.H. were in residence at Clare Hall, University of Cambridge. We thank N. J Shackleton of The Godwin Laboratory and R. G West of The Botany School for courtesies extended during our stay. Supported by NSF grant DEB-7910505 to New York University with assistance from the US Geological Survey.

Evidence for an early Plio-Pleistocene rainforest expansion in East Africa

P. G. Williamson

Department of Geological Sciences and
Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA

The Plio-Pleistocene palaeoenvironmental history of the Turkana Basin and neighbouring areas in north Kenya and southern Ethiopia has been a matter of considerable interest due to the important palaeoanthropological, palaeoarchaeological and palaeontological discoveries that have been made in this region[1-3]. The consensus is that although environmental oscillations have certainly occurred over the past 4 Myr, Plio-Pleistocene environments were generally comparable to the modern environment of the area[4]. However, the recent recovery of two taxa presently characteristic of the central African rainforest—the anacardiacean tree *Antrocaryon* and the prosobranch gastropod *Potadoma*—from a restricted chronostratigraphic horizon dating at ~3.3–3.4 Myr, at widely separated sites in the Turkana region, suggests that the general pattern of environmental stability was punctuated at this time by a brief but significant rainforest extension in East Africa. This brief humid interval apparently coincides with certain important molluscan immigrations, and can be broadly correlated with the first major episode of climatic deterioration in the Northern Hemisphere.

Recent reviews of Plio-Pleistocene palaeoenvironments in the Omo Valley and Koobi Fora areas of the Turkana Basin, north Kenya, have drawn on sedimentological, palaeontological and palaeobotanical evidence (see, for example, refs 1–4). Although a relatively xeric interval between 2.5 and 2.0 Myr has been postulated[5], the evidence for significant environmental change at this time has been questioned[4]. The general consensus seems to be that throughout the past 4 Myr the Turkana region has been characterized by a suite of terrestrial environments similar to those found at present—dry tropical scrub and grasslands of the 'Sudan savanna' replaced locally by limited gallery forest in the neighbourhood of perennial drainages[4]. However, several recent lines of evidence suggest that the general pattern of overall environmental stability in the latest Cenozoic of East Africa may have been briefly but significantly perturbed by an important humid episode at 3.3–3.4 Myr, an episode which entailed a major expansion of the central African rainforest. The suggestion that a humid episode occurred at this time was originally prompted by the discovery of fruits of the anacardiacean rainforest genus *Antrocaryon*[6] in the 'Brown Sands' locality of the Usno Formation, a short stratigraphic distance above tuff U10, and from Member A1.1 of the Shungura Formation in the lower Omo Valley (see Fig. 1), immediately underlain by tuff A and overlain by tuff B. Tuff U10 is considered to be a lateral correlate of tuff B of the Shungura Formation (F. H. Brown, personal communication), and tuff B itself is now considered a lateral correlate of the Tulu Bor Tuff from the Koobi Fora area[7,8] The age of this latter horizon is considered to be ~3.35 Myr, on the basis of its stratigraphic position between the immediately overlying Toroto Tuff (firmly dated at 3.32∓0 02 Myr) and the underlying Lokochot Tuff[9]. On the basis of geochemical comparisons, the Lokochot has been correlated with tuff A of the Shungura, which is known to lie close to the boundary between

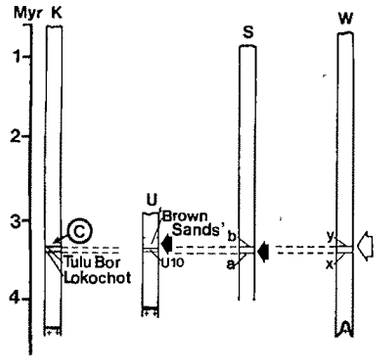

Fig. 1 Stratigraphic distribution of *Antrocaryon* (solid arrows) in the Usno (U) and Shungura (S) formations of the Omo Valley; occurrence of *Potadoma* (open arrow) in sections west of Lake Turkana (W) and the earliest African occurrence of *Corbicula* (C), in the Koobi Fora area (K). a, Tuff A of the Shungura Formation, which can be correlated with the Lokochot Tuff of the Koobi Fora area and also with a tuff (indicated here by x) in the areas west of Lake Turkana; b indicates tuff B of the Shungura Formation, which can be correlated with Tuff U10 of the Usno Formation, with the Tulu Bor Tuff of the Koobi Fora Formation, and with a tuff (indicated here by y) in the area west of Lake Turkana. Note the extremely restricted stratigraphic distribution of both *Potadoma* and *Antrocaryon*, and the fact that their occurrence coincides closely with the first African record of *Corbicula*. Data from various sources. The geographical distribution of these occurrences is indicated in Fig. 2. General chronostratigraphic framework after Brown *et al*[9]

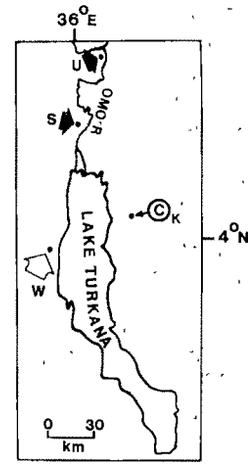

Fig. 2 Geographical location of occurrence of *Antrocaryon* (solid arrows) in the Usno (U) and Shungura (S) formations of the Omo Valley; *Potadoma* (open arrow) in the area of the Lomekwi drainage (W), west of Lake Turkana, and the first African occurrence of *Corbicula* C in area 129 of the Koobi Fora area (K) east of Lake Turkana.

Fig. 3 Present distribution of *Antrocaryon* and *Potadoma* in Africa. Black areas indicate present co-occurrence of *Antrocaryon* and *Potadoma*, except the small isolated area to the north, in which *Potadoma* occurs alone. Grey (stippled) areas indicate the present distribution of *Antrocaryon*. The circled area (T) indicates the location of the Turkana Basin Distribution of *Antrocaryon* after Bonnefille and Letouzey[6]; distribution of *Potadoma* after Brown[13].

the Gauss and Gilbert chrons; the Lokochot/tuff A horizon must accordingly date at ~3.42 Myr[9]. *Antrocaryon* in the lower Omo Valley is therefore confined to an interval from ~3.3 Myr to ~3.4 Myr. In addition to the occurrence of *Antrocaryon* in the Omo Valley deposits, the striking development of palaeosols in Member B has been considered evidence for humid conditions[10], and the mammal fauna from Member B10 contains rodents and prosimians (notably *Galago*) which have been interpreted as indicating a rainforest setting and forest connections with central Africa[11]. However, the various sites from which this evidence was obtained cover a relatively small area of the Omo Valley and all are fluvial deposits in close proximity to the presumed axis of the original Omo drainage[4]. Consequently, the evidence for rainforest conditions around the tuff B level could simply reflect a restricted local development of riverine gallery forest rather than a regionally significant rainforest expansion, as Brown[4] and others have pointed out[6].

The suggestion that a regionally significant humid episode and concomitant rainforest expansion occurred at 3.3–3.4 Myr in northern Kenya and southern Ethiopia is greatly strengthened by the recent discovery of the rainforest prosobranch *Potadoma*[12] from two faunas, separated stratigraphically by some 2 m, in the Lomekwi drainage area west of Lake Turkana some 60 km south of the Omo Valley (see Fig. 2). These faunas occur at the level of a tuff which has been correlated, on geochemical grounds, with the Tulu Bor (U10; tuff B) horizon[9] (see Fig. 1); this occurrence of *Potadoma* constitutes the only definite record of this west and central African genus in East Africa[12].

Both *Antrocaryon* and *Potadoma* are at present restricted to the central African rainforest[6,12,13]; indeed, their joint distribution essentially delimits the present distribution of rainforest in central Africa (see Fig. 3). The simultaneous occurrence of these distinctive taxa in sections up to 150 km apart in the Turkana region at 3.3–3.4 Myr strongly suggests, therefore, a dramatic expansion of humid rainforest conditions in the area at this time. However, the extremely restricted chronostratigraphic distribution of these taxa in the Turkana area deposits suggests that this period of enhanced humidity was relatively brief. The regional nature of this climatic change may also be reflected by the fact that a fauna some 8 m above the Tulu Bor Tuff in collection area 129 of the Koobi Fora area has recently provided the first African record of the primarily Eurasian bivalve *Corbicula*[14]. *Corbicula* has a long Cenozoic record in southern Eurasia, but is a comparatively recent addition to the African malacofauna[15]. *Corbicula* is unknown from any African malacofaunas definitely pre-dating its occurrence in area 129; it is absent from faunas lower in the Koobi Fora Formation[14], from the lower Usno or Mursi formations or the Basal Member of the Shungura in the Omo Valley[16], from the Lothagam or Kanapoi formations in the southern Turkana area[16], and from deposits such as the Kaiso Formation in the western rift[15]. However, the genus predominates in the majority of faunas in the Koobi Fora Formation subsequent to its first appearance above the Tulu Bor level in area 129 (ref. 14), and *Corbicula* is now one of the most abundant and widespread African freshwater bivalves[18]. A regional episode of enhanced humidity, as suggested by the occurrence of *Antrocaryon* and *Potadoma*, may well have encouraged the immigration of *Corbicula* from southern Eurasia by enhancing hydrographical connections between the latter area and northeastern Africa. However, it should be noted that in area 129 the Tulu Bor is overlain by a disconformity[8], and the first occurrence of *Corbicula* may therefore post-date the Tulu Bor by a greater interval than that indicated in Fig. 1, although no evidence of disconformity is apparent between the upper surface of the Tulu Bor and the fauna yielding *Corbicula*. Any molluscan interchange between north-east Africa and southern Eurasia is unlikely to have been strictly 'one-way', and it is therefore of interest that the only known Eurasian occurrence of the African prosobranch *Bellamya unicolor* (Olivier) is from the 'Erq el-Ahmar beds of the

central Jordan Valley[19]; these beds are not directly dated but immediately overlie a basalt (the 'cover basalt') recently dated at ~3.2 Myr[24].

A major humid episode and consequent expansion of rainforest in East Africa at 3.3–3.4 Myr should be reflected by palaeoclimatic events elsewhere. In fact, the regional episode of rainforest expansion discussed here appears to correspond broadly to the early Gauss 'ice-age transition' episode, long considered to signify the initial formation of significant Northern Hemisphere ice sheets[20–23]. However, this transition episode essentially represents a unidirectional palaeoclimatic deterioration reflecting the onset of ice-age conditions[23], whereas the extremely restricted chronostratigraphic distribution of *Antrocaryon* and *Potadoma* in East Africa suggests a palaeoclimatic 'punctuation' or 'overshoot' of relatively brief duration.

I thank F. H. Brown, who originally located the *Potadoma* material and provided stimulating discussions as to its significance, and D. S. Brown and J. P. Kennett for valuable comments

Reconstruction of prehistoric plant production and cooking practices by a new isotopic method

Christine A. Hastorf*‡ & Michael J. DeNiro†

Departments of Anthropology* and Earth and Space Sciences and Archaeology Program†, University of California, Los Angeles, California 90024, USA

As archaeological research has focused increasingly on economic questions, archaeologists have collected data that reflect production and consumption of food. Macrobotanical remains, recovered by methods such as water flotation, often provide the most available and relevant data concerning production in archaeological contexts. However, these data do not necessarily reflect the proportion of crops that were consumed[1]. Here we present a new method, based on isotopic analysis of burnt organic matter, allowing the characterization of previously unidentifiable plant remains extracted from archaeological contexts. We used this method to reconstruct prehistoric production, preparation and consumption of plant foods, as well as the use of ceramic vessels, in the Upper Mantaro Valley region of the central Peruvian Andes[2]. The method will be of use to archaeologists studying these prehistoric activities in other areas of the world.

The basis for the isotopic method used here can be summarized as follows. Nitrogen isotope ratios separate modern plants into two groups: legumes, capable of fixing atmospheric nitrogen, and non-leguminous plants, which must use nitrogen from the soil[3,4]. Carbon isotope ratios also separate modern plants into two groups, C_3 plants and C_4 and crassulacean acid metabolism (CAM) plants, which differ in the enzymes that catalyse initial CO_2 fixation[5–7]. Because all legumes are C_3 plants and no C_4 or CAM plant is known to fix atmospheric nitrogen, combined C and N isotope analysis can be used to separate living plants into three groups: legumes, non-leguminous C_3 plants, or C_4 and CAM plants[3–7]. Prehistorically burnt domesticated plants, identified to the species level and assigned to one of the three plant groups on the basis of this taxonomic information[3–8], retain their isotopic identities during burning and fossilization (Fig. 1*a*). Thus, isotope ratios can be used to separate prehistoric burnt plant remains into the same three groups as modern plants.

To gain information on crop production, we used the isotopic method described above to classify prehistoric plant fragments, extracted from the soil by flotation techniques, that could not be identified by morphological criteria because they had been burned so extensively. These specimens came from three sequential occupation phases in the Upper Mantaro Valley region, namely the Early Intermediate Period/Middle Horizon (EIP/MH, 200 BC to AD 1000), the Huanca I period (H-I, AD 1000–1200) and the Huanca II period (H-II, AD 1200–1470)[2]. The identification of the three phases is based on changing settlement patterns, ceramic type frequencies and radiocarbon dates[9,10]. Results of the isotopic identification of the morphologically unidentifiable plant remains (Fig. 1*b*) were added to the much larger database of plant specimens identified by morphological analysis[10]. From these data we determined the changes that occurred in plant production during the three occupation phases in the Upper Mantaro Valley region (Table 1). (Because we have focused on plant production and consumption, we have included only the major agricultural crops of the region in constructing the table.) Among the indigenous crops, lupines (*Lupinus mutabilis*) and beans (*Phaseolus vulgaris*) are legumes, maize (*Zea mays*) is the only C_4 plant (there are no CAM plants) and the remaining plants are all non-leguminous C_3 plants—namely *quinoa* (*Chenopodium quinoa*) and the tubers, which include potatoes (*Solanum tuberosum, Solanum juzepczukii*), *oca* (*Oxalis tuberosa*), *olluco* (*Ullucus tuberosus*) and *mashua* (*Tropaeolum tuberosum*)[10]. The data in Table 1 indicate that during each phase, legumes and C_4 plants were produced in roughly equal amounts, but non-leguminous C_3 plants predominated as the major crops. During the H-I period there was also increased production of C_4 plants (maize) and legumes compared with the preceding and subsequent periods.

Table 1 Domestic plant group frequencies for three sequential occupation phases of the Upper Mantaro Valley

Period	Plant group frequencies (%) Non-leguminous C_3	C_4	Legumes	No. soil samples analysed
EIP/MH	74	29	23	171
H-I	83	43	43	175
H-II	69	13	20	265

Values for each period represent the percentage of soil samples weighing 6 kg that contained the indicated plant group. This measurement is based on presence/absence of specimens in each sample and not on internal density of the plant type. The frequencies[11–13] do not total 100% but show the relative presence of plants The provenences of the sites are given in ref 10

‡ Present address Department of Anthropology and Center for Ancient Studies, University of Minnesota, Minneapolis, Minnesota 55455, USA

To study prehistoric cooking practices and associated vessel function, we determined the isotope ratios of the organic matter encrusted on the inside surfaces of ceramic vessel shards excavated from habitations in the Upper Mantaro Valley region. Only the plainest self-slipped jar type had encrustations, although these encrustations did not occur on every self-slipped shard. From vessel reconstructions, we found that the encrustations covered the bottoms but not the upper walls of the vessels.

All shards with visible encrustations were scraped to collect the organic matter. The 71 shards whose encrustations were analysed isotopically were chosen at random from all encrusted shards collected at the five sites spanning the three time periods for which we have the production data described in Table 1.

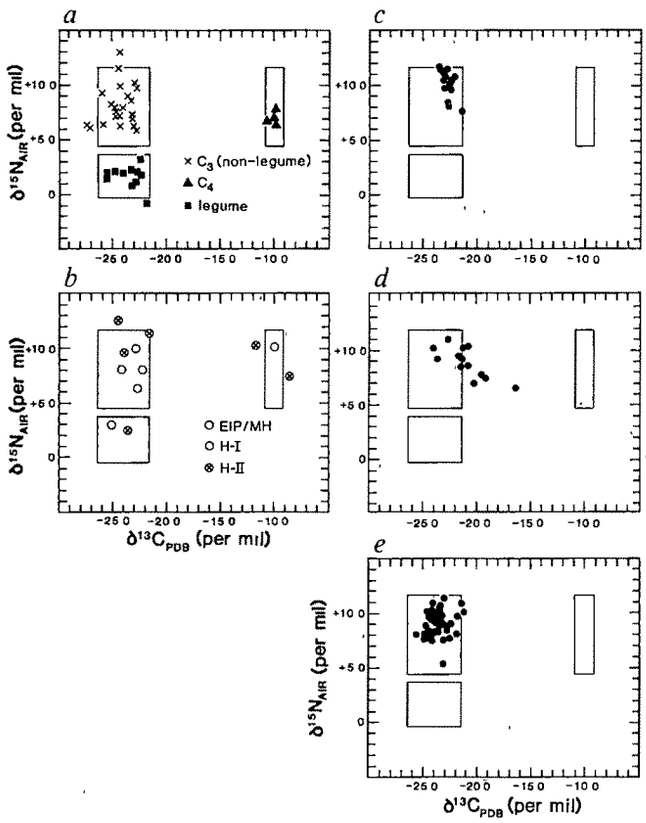

Fig. 1 C and N isotope ratios of burnt plants and of encrustations from the insides of ceramic vessel shards excavated from archaeological sites representing three continuous phases of occupation in the Upper Mantaro Valley area. The $\delta^{13}C$ and $\delta^{15}N$ values are given for: *a*, prehistoric burnt plant fragments assigned to the indicated groups based on morphological criteria; *b*, prehistoric plant fragments too extensively burnt to allow such identification; *c–e*, vessel shard encrustations from the Early Intermediate Period/Middle Horizon (*c*), the H-I period (*d*) and the H-II period (*e*) Plant fragments and shard encrustations were cleaned in an ultrasonic bath and freeze-dried before the determination of their isotope ratios by methods described in ref. 8. The identified prehistoric plants in *a* came from the three occupation phases and include all the local indigenous Andean crops discussed in the text[8]. The boxes in each graph indicate the means ±2 s.d. of the $\delta^{15}N$ values for the identified legumes and non-leguminous plants and of the $\delta^{13}C$ values for the identified C_3 and C_4 plants shown in *a* Isotope ratios of modern plants in the three groups[8] are similar to those indicated by the boxes. Isotope ratios are given as δ^*X values, where

$$\delta^*X = \left[\frac{(^*X/X)_{\text{sample}}}{(^*X/X)_{\text{standard}}} - 1\right] \times 1{,}000 \text{ per mil}$$

For $\delta^{13}C$ values, $^*X/X = {}^{13}C/{}^{12}C$ and the standard is the PDB carbonate (C_{PDB}). For $\delta^{15}N$ values, $^*X/X = {}^{15}N/{}^{14}N$ and the standard is atmospheric nitrogen (N_{AIR}). The precisions for determination of both the $\delta^{13}C$ and $\delta^{15}N$ values are ±0.2 per mil.

For the purposes of this analysis, we assume that our random sample is representative of the total population of encrusted shards.

Analysis of the encrusted organic matter by light and scanning electron microscopy (SEM) indicates that all morphological characters useful for identification had been destroyed during burning. Three lines of evidence indicate that these organic encrustations originated from plant material that was boiled and mashed before charring. First, SEM analysis of the encrustations did not reveal the presence of bone fragments, which would have survived the burning process. Second, the atomic C/N ratios of the prehistoric encrustations were similar to those of encrustations we made by cooking and then charring modern food plants from the Upper Mantaro Valley region onto ceramic vessels, but higher than those we produced by the same process using fresh meat. The ranges and means ±1 s.d. of the C/N ratios were as follows: prehistoric encrustations, 8.2–19.3/12.8 ± 2.1 ($n = 71$); modern plant encrustations, 8.2–38.8/23.4 ± 10.0 ($n = 8$); modern meat encrustations, 4.4–6.1/5.3 ± 0.8 ($n = 6$), where n is the sample size. Third, all of the prehistoric encrustations analysed were evenly distributed on the inside surfaces of the shards. The only way we could reproduce this type of distribution was by boiling and mashing fresh plants before burning them onto ceramic vessels. Dry-toasting before charring produced a spotty distribution of burnt material on the vessel. Experiments with modern plants demonstrate that isotope ratios are not substantially altered when plants are cooked and then burned onto ceramic vessels. Thus, isotope ratios of the shard encrustations indicate the type of plants cooked in these vessels.

The isotopic data for shard encrustations from the EIP/MH period (Fig. 1*c*) and the H-II period (Fig. 1*e*) show a strong clustering in the C_3 plant group box. For the intervening H-I period (Fig. 1*d*), however, the isotopic data provide evidence of C_4 plants mixed with C_3 plants in some of the encrusted samples. With the possible exception of a single sample from the H-II period (Fig. 1*e*), none of the shard encrustations shows isotopic evidence of legumes having been cooked in significant amounts in these vessels.

The ceramic shards with encrustations came from large self-slipped jars, from midden and floor excavation proveniences, suggesting that they were fragments of cooking vessels. The results from the isotopic analysis of these body shards support the hypothesis that these large jars were used for daily domestic food preparation. From this, we assume that food preparation practices reflect food consumption.

We conclude that the prehistoric inhabitants of the Upper Mantaro Valley region used these ceramic jars to cook C_3 plants alone or C_4 plants and C_3 plants together, either simultaneously or sequentially, but did not cook legumes, either alone or in combination with non-leguminous plants. These conclusions are consistent with modern cooking practices in this part of the Andes (C.A.H., unpublished). Today C_3 plants (*quinoa* or tubers) are often boiled alone for a meal, whereas when maize is boiled, it is generally prepared with C_3 plants and spices. Comparison of modern and prehistoric processing of legumes is complicated by the present-day use of fava beans (*Vicia fava*) and peas (*Pisum* sp.), which have been introduced from Europe[10]. Fava beans and peas are boiled as well as dry-toasted at present, whereas the indigenous legume *Lupinus mutabilis* is a casual food and tends to be toasted or eaten raw. *Phaseolus vulgaris*, although indigenous, is not in common use today. Although we do not know whether introduction of new plant foods influenced traditional cooking practices, our isotopic analysis of the shard encrustations indicates that present-day cooking patterns for indigenous plants also existed in the past.

Comparison of the consumption data (Fig. 1*c–e*) with the production data (Table 1) indicates that temporal changes in food preparation paralleled changes in food production for the C_3 and C_4 plant groups. The absence of parallel trends in the two activities for legumes and non-leguminous plants is probably related to how indigenous legumes were prepared. The evidence for maize on some H-I period shards (Fig. 1*d*), in association

with evidence of increased maize production at that time (Table 1), suggests that the additional maize available to the population during this period was eaten as a bulk carbohydrate. We suspect that during all three periods maize was being consumed as *chicha* (fermented beverage) and *cancha* (toasted corn). Because there is no evidence for significant differences in social status during the H-I period[10], differential access to resources based on social position cannot have helped to produce evidence for increased consumption of maize during this period.

The isotopic method described here can be used to characterize plant materials burned onto ceramic vessels (whether the vessels were everyday cooking wares, storage jars or ceremonial items) in areas that have plants from more than one of the three isotopically identifiable plant groups. This method should also be applicable to organic encrustations on vessel exteriors, identifying plant groups used prehistorically as fuel

Population dynamics of *Schistosoma mansoni* in mice repeatedly exposed to infection

J. A. Crombie & R. M. Anderson

Department of Pure and Applied Biology,
Imperial College of Science and Technology, Prince Consort Road,
London SW7 2BB, UK

Studies of host resistance to parasite infection are usually based on experimental designs involving a primary infection and subsequent challenge exposure, resistance being recorded as the percentage reduction in parasite establishment in challenged hosts when compared with that in uninfected animals[1-8]. Few studies have focused on the dynamic nature of helminth establishment and mortality (and their presumed dependency on the rate of current exposure and past experiences of infection) in hosts repeatedly exposed to low levels of infection[9-11]. Here, we report the results of population studies on the dynamics of resistance to *Schistosoma mansoni* infection (a helminth parasite) in mice repeatedly exposed to cercarial invasion. Parasite burdens created by different levels and durations of exposure to infection reflect a dynamic interplay between rates of helminth establishment and mortality. Depending on the intensity of exposure, changes in worm load with duration of host infection vary from monotonic growth to a stable average parasite burden to convex curves in which the average load attains a maximum value before decaying in old animals. These trends are similar to observed patterns of *S. mansoni* infection in human communities[12-14].

Under conditions of constant exposure to infection and constant worm mortality, and in the absence of acquired resistance to infection, average helminth burdens per host will rise monotonically as the duration of exposure increases to a stable equilibrium (an 'immigration-death process')[15]. Patterns of change in the intensity of *S. mansoni* infection in human communities with host age, however, often show a rise to a maximum value in teenage or young adult age groups and a decline thereafter[12-16]. It is not known whether the observed decline in older age groups reflects age dependency in the rate of exposure to infection (that is, an ecological process) or acquired resistance to worm establishment (an immunological process)[16,17]. We used a laboratory model to generate age-intensity curves of *S. mansoni* infection (a Puerto Rican strain) in inbred mice (CBA/Ca) by repeated exposure to constant numbers of cercariae, using four levels of cercarial exposure (Fig. 1*a*, *b*). Separate experiments revealed that ~50% of the cercariae to which a naive host was exposed became established as mature adult worms (5-week maturation period) (Fig. 1*d*).

The severity of the initial rise in mean worm burden with age of the host and the maximum worm burden attained are dependent on the density of cercariae to which the host is exposed At the lowest infection dose, mice survived infection well and the experiment ran for 50 weeks with worm burdens attaining a stable plateau of ~4-6 parasites per mouse. Burdens of this magnitude may produce disease that most closely resembles human hepatosplenic schistosomiasis[18]. At higher exposure levels some host mortality occurred (Fig 1*a*, *b*). In the two highest exposure experiments there was a decline in parasite burden in older mice, the severity of which was not accounted for by a dependence between host death rate and parasite burden.

As the rate of exposure of the host to infective stages was kept constant with time, these observations suggest that the acquisition of resistance to infection occurs as the duration and intensity of exposure increases. The convex pattern (Fig. 1*a*) recorded for the highest exposure rate could have arisen as a consequence of a time-delayed density-dependent mechanism created by limitation of resources in the host, as opposed to host defence mechanisms. This seems to be unlikely for two reasons. First, there is clear evidence for immunological response to *S. mansoni* infections[8]. Second, our experiments generated comparatively low burdens of mature and juvenile worms when compared with the much higher worm loads that can be harboured in the mesenteric veins[8].

Perfusion of infected mice led to the recovery of juvenile worms throughout all the experiments, which suggests that parasites can become established in hosts despite long durations of past experience of infection and the presence of mature adult worms. The observed patterns of infection represent a dynamic interplay between parasite establishment (at a rate $\bar{\Lambda}$) and worm mortality (at a rate per parasite of μ). The rate of change of the mean worm burden per mouse, $M(t)$ with respect to time can be described by an immigration-death process where

$$\frac{dM(t)}{dt} = \bar{\Lambda}(\bar{M}(t)) - \mu M(t) \qquad (1)$$

In agreement with current understanding of the mechanism of immunity to *S. mansoni* infection in mice[8], we assume that acquired resistance acts to decrease the rate of parasite establishment, $\bar{\Lambda}(\bar{M}(t))$, in a manner dependent on the accumulated experience of past infection, $\bar{M}(t)$, where $\bar{M}(t) = \int_0^t M(t')dt'$.

For simplicity we assume a linear dependency where

$$\bar{\Lambda}(\bar{M}(t)) = \Lambda\left[1 - \varepsilon\int_0^t M(t')e^{-\sigma(t-t')}\,dt'\right] \qquad (2)$$

with the constant ε denoting the efficacy of acquired resistance, described in more detail in the accompanying paper[19]. We further assume that the 'immunological memory' of past experience of infection is finite and decays as the time interval between the present and past experience increases with an average memory duration of $1/\sigma$ (ref. 19). The model contains four adjustable parameters, Λ, μ, ε and σ. Estimates are available for Λ and μ (see Fig 1*c*, *d*) on the basis of our experimental design, and a crude estimate can be obtained for ε (by noting

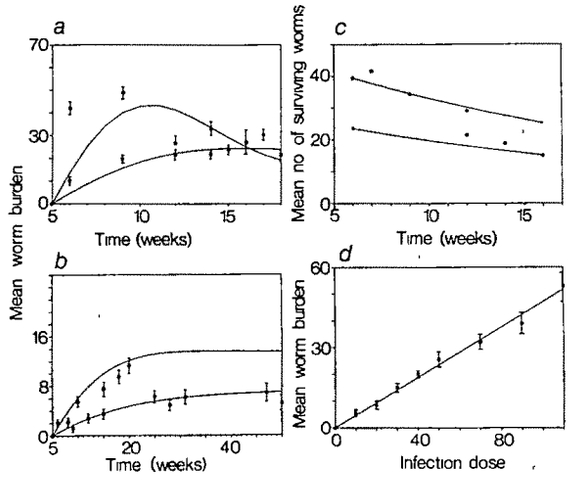

Fig. 1 *a*, *b*, Worm recovery through time from trickle infection experiments. Groups of 10 mice were exposed to infection at weekly intervals by paddling for 0.5 h in tanks containing a suspension of cercariae (of age <2.5 h) in 200 m dechlorinated tap water at 25 °C. Four infection densities were used: 10, 30, 100 and 300 cercariae per group per week. Worms were recovered at intervals post-infection by perfusion of the hepatic portal system with citrated saline and by general dissection. Symbols denote the mean worm recovery with standard error bars. Note that the abscissae start at 5 weeks because of the maturation delay (~5 weeks) of *S. mansoni* in laboratory mice. Solid line, predicted worm recovery calculated from the immigration-death model described in the text (equation (1)). For $(\mu-\sigma)^2>4\varepsilon\Lambda$ the solution of equation (1) is given by

$$M(t)=A+\frac{\Lambda}{\lambda}\left[\frac{(p_1+\sigma)e^{p_1 t}}{p_1}-\frac{(p_2+\sigma)e^{p_2 t}}{p_2}\right]$$

where $A=\Lambda\sigma/(\sigma\mu+\varepsilon\Lambda)$; $p_1=[-(\mu+\sigma)+\lambda]/2$, $p_2=-(\mu+\sigma+\lambda)/2$ and $\lambda=[(\mu-\sigma)^2-4\varepsilon\Lambda]^{1/2}$. When $4\varepsilon\Lambda>(\mu-\sigma)^2$ the solution adopts the form

$$M(t)=A+e^{-(\mu+\sigma)t/2}\left[\frac{2\Lambda}{\theta}\sin\left(\frac{t\theta}{2}\right)\left[1-A\left(\frac{\mu+\sigma}{2\Lambda}\right)\right]-A\cos\left(\frac{t\theta}{2}\right)\right]$$

where $\theta=[4\varepsilon\Lambda-(\mu-\sigma)^2]^{1/2}$. Equation (2) is a crude mimic of current understanding of acquired resistance mechanisms, as the value of ε must be small to prevent negative infection rates. The choice of this function was determined by analytical convenience and the observation that establishment decays slowly as the summed past experience of infection rises (negative infection rates prevented by a very small ε value). If the net infection rate in equation (1) <0 (that is, ε large), acquired immunity is assumed to influence parasite establishment and survival. ***a***, Record of the results for cercarial exposure levels of 10 and 30 infective stages per week (model parameter values $\varepsilon=0.0085$ per week, $\sigma=0.2$ per week and $\mu=0$ 045 per week (see *c*). The values of Λ calculated by means of the relationship shown in *d* were 4.711 and 14.13 per week, respectively. ***b***, Similar to *a* but the results for cercarial exposure levels of 1 and 3 infective stages per week ($\Lambda=0.4711$ and 1.413 per week, respectively, other parameter values as defined for *a*). ***c***, Adult worm survival over a 10-week period post-maturation. Two examples are shown where initial adult worm densities at week 6 of infection were ~40 and 25 parasites per mouse The symbols denote observed means (from 10 mice) and the solid lines denote the fit of an exponential decay survival model with constant death rate $\mu=0.045$ per week ***d***, Worm recovery 6 weeks post-infection of naive mice exposed to a single infection of varying intensity (0-110 cercariae). Symbols denote observed mean recoveries (10 mice) (the underlying distribution of worm numbers per inbred mouse was Poisson in form) and the solid line is the best-fit linear model with slope $b=0.4711$ (that is, 40% of invading cercariae established within the host at week 6) where $r^2=0.99$. Vertical bars denote 95% confidence limits The fit of the model to observed trends is poor in the early stages (weeks 6 and 9) of the cercariae/mouse/week experiment (*a*) as a consequence of higher than average established rates in these batches of experimental animals (higher than the average value of 47% of exposure dose recorded in *d*).

the decline in juvenile worm establishment as a function of accumulated past experience of infection). At present nothing is known about the duration of immunological memory, but model predictions crudely mimic observed changes in parasite burden as the duration of exposure to infection increases, with a fixed value of $1/\sigma=5$ weeks (obtained by trial and error) (Fig. 1*a*, *b*).

The model (with no adjustable parameters other than that (Λ) set by the experimental design) is able to reflect accurately monotonic growth to a stable parasite burden for low exposures to infection and convex curves for high rates of exposure. This provides tentative support for the view that convex age-intensity curves of *S. mansoni* infection in human communities may arise partly as a consequence of acquired resistance. Observed pattens in man are probably generated by a combination of ecological and immunological processes[20].

To explore the significance of immunological memory, curative chemotherapy was used in conjunction with repeated exposure to infection. For low and medium levels of exposure (1 and 10 cercariae per week), there were no significant differences following drug treatment in mice with 9, 12 and 15 weeks previous experience of continual infection, when compared with primary trickle infections (Fig. 2*a*, *b*, *c*, *d*). Resistance following chemotherapy has been the subject of previous studies but the

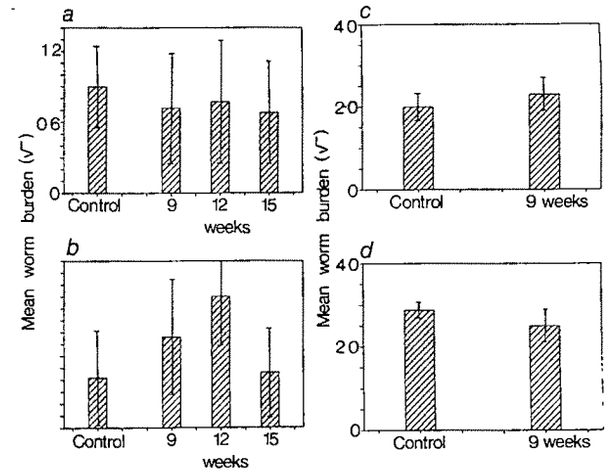

Fig. 2 Worm recovery following curative chemotherapy. Praziquantel was administered at a dose of 250 mg per kg divided into three applications given at 4-h intervals during a single day[21]. ***a***, The control was exposed to infections of 10 cercariae per group of mice per week for 6 weeks before autopsy. The experimental groups (10 mice per group) were exposed to an identical repeated infection for 9, 12 and 15 weeks before chemotherapy; autopsy was performed after 6 weeks of reinfection. One-way analysis of variance on transformed data (a square-root transformation based on the observed Poisson distributions of parasite numbers per mouse) showed no significant differences between treatments and control at the 5% level. Note, however, that the type II errors associated with this test (and those associated with the data presented in *b*, *c* and *d*) are large because of small sample sizes (10 mice per group). Studies involving much larger samples are required for future work. ***b***, As for *a* except that worm recovery was performed 9 weeks after initial infection in the control and after 9 weeks reinfection following chemotherapy in the experimental groups. One-way analysis of variance on transformed data ($\sqrt{x}$) showed no significant differences between treatments and control at the 5% level. ***c***, The control group was exposed to infections of 100 cercariae per group of mice per week for 6 weeks before autopsy The experimental group was exposed to 9 weeks infection before treatment (100 cercariae per week) and to 6 weeks reinfection post treatment. Student's *t*-test ($\sqrt{x}$) showed no significant differences at the 5% level. ***d***, As for *c* but with worm recovery performed 9 weeks after initial infection in the control group and after 9 weeks reinfection in the experimental group. No significant difference at the 5% level (*t*-test). *a*–*d*, Vertical lines show the 95% confidence limits. Note that the sample sizes of experimental animals (10 mice per group) were low and further studies are required to confirm these observations

results (based on primary and single challenge experiments) are inconclusive[10-12]; residual protective immunity was apparent in some studies but not in others. Our results from continual exposure experiments tentatively suggest that the expulsion of adult worm burdens eliminates the 'memory' of previous infections.

Studies of parasite establishment and mortality in hosts continually exposed to helminth infection have many advantages over more conventional experimental designs when seeking information to help interpretation of observed epidemiological trends in human communities. Where rates of parasite establishment depend on previous experience of infection, horizontal or longitudinal profiles of changes in parasite burden with age can vary from growth to a stable plateau in parasite load in areas of low transmission intensity to convex curves with marked declines in infection in older age classes in areas of high transmission intensity.

Despite much research on immunological responses to helminth parasites, knowledge of the dynamic interplay between levels of herd immunity in humans and the rates of exposure, establishment and mortality of parasites remains limited[1-7]. We describe here a simple mathematical model for the population dynamics of helminth infections which mirrors the development of a degree of acquired immunity within populations which are genetically heterogeneous with respect to immunological responsiveness. We interpret observed patterns in the age-specific intensity of infection and attempt to understand the possible effects of control measures based on chemotherapy and vaccination. Mass chemotherapy can, in some circumstances, reduce the level of herd immunity such that average worm burdens in the adult age classes rise above their precontrol levels. When certain individuals or groups are predisposed to heavy infection[5,8,9], selective or targeted drug treatment can have significantly greater impact than mass or random application. Conversely, model predictions suggest that effective parasite control by vaccination (if and when vaccines become available) is difficult to achieve in communities that are genetically heterogeneous in their ability to mount protective responses to infection.

None of the existing epidemiological models of helminth transmission in human communities takes explicit account of acquired immunity, despite the growing volume of field[10-16] and laboratory-based studies[17-19] which attest to its significance as a determinant of parasite abundance. Infection with helminths and exposure to their diverse and complex antigens, generates varied and complex immune responses[4,7,18,20]. Acquired immunity seems to be characterized generally by a marked dependence on the degree of antigenic stimulation (the accumulated experience of infection over time), an ability to provide only partial protection against reinfection, and a transient efficacy[7,17-20]. Host responses seem to be most effective against the invading larval stages of helminth parasites and, as such, act to decrease the rate of parasite establishment within the host[7,18]. In endemic areas, humans seem continually to acquire parasites throughout life, although the average intensity of infection is often less in older than in younger age groups[21] (Fig. 1*a*, *b*). The degree to which intensity declines in the older people seems to be positively associated with the intensity of transmission (Fig. 1*a*, *b*). Much current debate centres on the relative roles of acquired immunity and age-specific changes in exposure to infection as determinants of such trends.

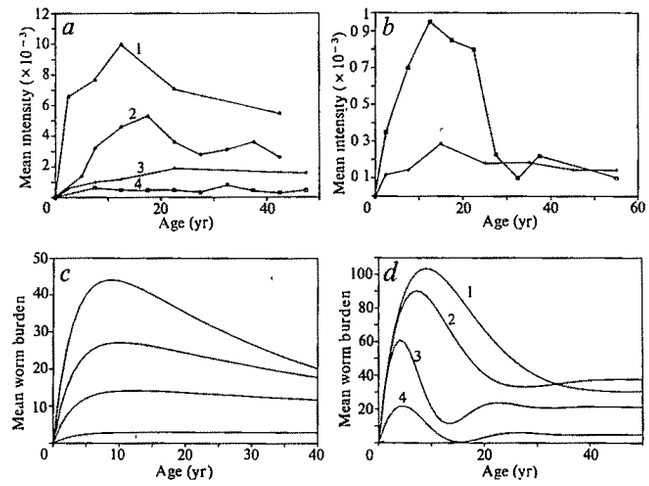

Fig. 1 Observed and predicted patterns of age-related changes in the average intensity of infection (horizontal cross-sectional profiles). *a*, Hookworm infection in communities with varying intensities of transmission. Data sources are: curves 1, 3, ref. 29; curve 2, ref. 30; curve 4, ref. 31. The indirect measure of hookworm burden (intensity) is mean eggs per g of faeces. *b*, Schistosome infection in areas of high[32] and low[33] transmission intensity. Intensity measured by eggs per g of faeces (Kato technique). Note how in both *a* and *b* the intensity profiles become convex in areas of high transmission intensity. *c*, Equilibrium/age-intensity curves ($\partial M(t, a)/\partial t = 0$) generated by the model defined in equation (1) (with $\Delta = 0$) with the following parameters (population assumed to be homogeneous): $\varepsilon = 0.0005$, $\sigma = 0.00001$, $\mu = 0.33$, $\Lambda = 17$ (top line); 10, 5 and 1 (bottom curve) (all rates are per yr). If the net infection rate in equation (1) < 0 (that is, ε large) acquired immunity is assumed to influence parasite establishment and survival. Note how the curves become convex in shape as the intensity of transmission increases (the value of Λ). *d*, Similar to *c* but with parameter values: curve 1, at age 10, $\Lambda = 10$, $\mu = 0.2$, $\varepsilon = 0.009$, $\sigma = 0.05$; curve 2, at age 10, $\Lambda = 30$, $\mu = 0.2$, $\varepsilon = 0.001$, $\sigma = 0.05$; curve 3, at age 10, $\Lambda = 30$, $\mu = 0.2$, $\varepsilon = 0.004$, $\sigma = 0.1$; curve 4, $\Lambda = 30$, $\mu = 0.2$, $\varepsilon = 0.005$, $\sigma = 0.02$ (all rates are per yr).

Current understanding of acquired immunity can be crudely captured by a model in which the rate of establishment of new parasites within individuals of a given age, *a*, is inversely correlated with some accumulated average experience of infection

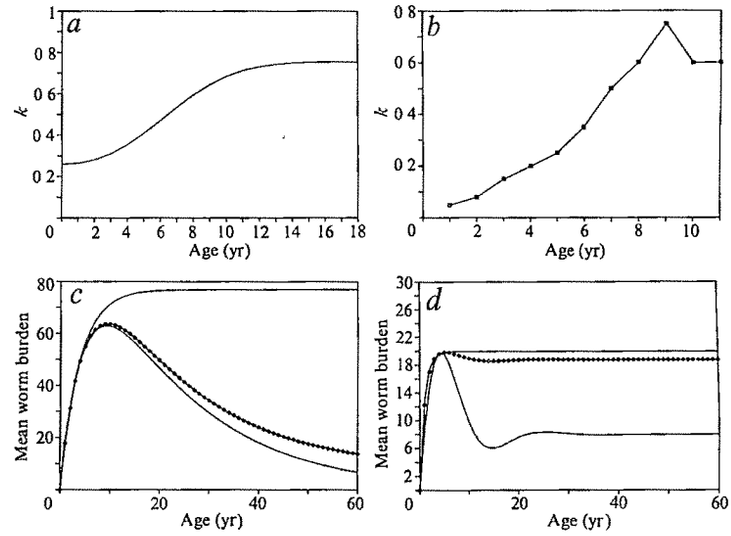

Fig. 2 Heterogeneity in 'immunological responsiveness' and exposure to infection. Model predictions for a population consisting of two types of individuals who represent proportions f_1 and f_2 of the total population, where $f_1+f_2=1$. where $M_1(t, a)$ is the mean worm lead of type I individuals (f_1) and $M_2(t, a)$ is the mean worm load of type II individuals (f_2) at time, t, of age, a, at equilibrium ($\partial M_1(t, a)/\partial t=\partial M_2(t, a)/\partial t=0$) the model takes the form

$$dM_1(a)/da=\Lambda_1\left[1-\varepsilon_1\int_0^a M_1(a')\,e^{-\sigma_1(a-a')}\,da'\right]-\mu_1 M_1(a)$$

$$dM_2(a)/da=\Lambda_2\left[1-\varepsilon_2\int_0^a M_2(a')\,e^{-\sigma_2(a-a')}\,da'\right]-\mu_2 M_2(a)$$

where the subscripts to the parameters denote differences in their values between type one and type two individuals. Here $\Lambda_i=R_{0i}(b+\sigma_i)\bar{M}$ where $1/b$ is the life expectancy of the human host, R_{0i} is the basic reproductive rate of the parasite in hosts of class i and $\bar{M}$ is the overall average worm burden in the entire population (average over all age classes and types),

$$\bar{M}=\sum_{i=1}^{2} f_i b\int_0^\infty M_i(a)\,e^{-ba}\,da$$

a, Predicted changes with age in the negative binomial parameter k (which varies inversely with the degree of parasite contagion within the host population)[5,21]. Model parameters: $\Lambda_1=1, f_1=0.9, \mu_1=\mu_2=1, \varepsilon_1=\varepsilon_2=0.01, \sigma_1=\sigma_2=0.1, \Lambda_2=20, f_2=0.1$; all are per yr. The differences in Λ reflect differing rates of exposure to infection (perhaps induced by behavioural differences between the two groups of individuals). *b*, Observed age-related changes in k for hookworm infection (*Necator americanus*) in a village community in India[34]. *c*, Predicted age-related changes in the mean worm burdens in type I individuals ($M_1(a)$) (top solid line), type II individuals ($M_2(a)$) (bottom solid line) and the total population $M(a)$ (diamond symbols). This example mirrors a population in which the wormy people (fraction f_1) are few in number ($f_1=0.1$) and are characterized by a short immunological memory ($\sigma_1=1$). The dominant proportion of the population ($f_2=0.9$) have a long-lasting memory ($\sigma_2=0.00001$, that is, lifelong). Parameter values: $\Lambda_1=\Lambda_2=20$, $\mu_1=\mu_2=0.25$, $\varepsilon_1=\varepsilon=0.05$; all per yr. *d*, Similar to *c* but the dominant proportion of the population are poor immunological responders to infection ($f_1=0.9$) with a low rate of acquisition of immunity ($\varepsilon_1=0.00001$) when compared with the small fraction of good responders ($\varepsilon_2=0.01$). Parameter values: $\Lambda_1=20$, $\Lambda_2=10$, $\mu_1=1$, $\mu_2=0.25$, $\sigma_1=\sigma_2=0.1$, all per yr.

through time. Laboratory studies of mice repeatedly exposed to helminth infection provide some support for this view (see accompanying paper[19]). We make the simple assumption that the rate of parasite establishment declines linearly as the accumulated experiences of exposure to infection and worm load increase with age. 'Immunological memory' of these past experiences is assumed to last only for a finite period of time. These assumptions can be expressed as a single partial differential equation denoting changes in the mean worm burden, $M(t, a)$, with respect to time t and age a:

$$\frac{\partial M(t,a)}{\partial t}+\frac{\partial M(t,a)}{\partial a}$$
$$=\Lambda(t)\left[1-\Delta\int_0^a \Lambda(t)\exp[-\sigma_2(a-a')]\,da'\right.$$
$$\left.-\varepsilon\int_0^a M(t,a')\exp[-\sigma_1(a-a')]\,da'-\mu M(t,a)\right] \quad (1)$$

Here $\Lambda(t)$ denotes that per capita rate of infection at time t; it is a function of the average fecundity of mature worms, infective stage life expectancy (for indirectly transmitted infection this includes the life expectancy of short-lived vectors or intermediate hosts), host density and the probability of host contact with infective stages or infected vectors[21]. The parameters Δ and ε record the strength of acquired immunity as it acts to decrease parasite establishment resulting from either exposure to infection (Δ) or adult parasite burdens (ε); $1/\sigma_2$ and $1/\sigma_1$ reflect the average duration of the immunolgical memory of past exposure and past worm loads, respectively (if $\sigma_i=0$, memory is life-long; if $\sigma_i=\infty$ memory is absent); and $1/\mu$ denotes the life expectancy of the adult parasites in man. Here, for simplicity, we set $\Delta=0$ because past worm burdens partly reflect past exposure. However, equation (1) has the flexibility to allow for the somewhat different ways in which immunity is influenced by exposure to infection as well as by the burden of established worms.

The acquisition of immunity to parasite establishment is assumed to be the only major constraint on parasite population growth (parasite fecundity and mortality are taken to be independent of parasite density in the present model; such effects are discussed elsewhere[5,9,21,22]). Equation (1) assumes that the human population is homogeneous in its immunological response to parasite invasion (that is, ε is a constant). This assumption can be relaxed by dividing the population into groups ($f_1 \ldots f_n$) in which ε, μ, Λ and σ adopt different values (Λ_i, ε_i, μ_i and σ_i). At equilibrium ($\partial M(t, a)/\partial t=0$), the mean worm burden at age a, $M(a)$, is simply (with $\Delta=0$ and λ real[19]),

$$M(a)=A+(\bar{\Lambda}/\lambda)\left[\frac{(p_1+\sigma)}{p_1}e^{p_1 a}-\frac{(p_2+\sigma)}{p_2}e^{p_2 a}\right] \quad (2)$$

where

$$A=\bar{\Lambda}\sigma/(\sigma\mu+\varepsilon\bar{\Lambda}); \qquad p_1=(\lambda-\mu-\sigma)/2;$$
$$p_2=-(\lambda+\mu+\sigma)/2; \qquad \lambda=([\mu-\sigma]^2-4\varepsilon\bar{\Lambda})^{\frac{1}{2}};$$
$$\bar{\Lambda}=(\sigma+b)(R_0-1)(b+\mu)/\varepsilon;$$

and $1/b=$ human life expectancy (assuming a type II survival curve). The quantity R_0 denotes the basic reproductive rate of the parasite[5,9,21,22] ($R_0>1$ for parasite persistence). Stochastic models for the distribution of worms among hosts in the equilibrium state reveal that the probability distribution of worm numbers per host is Poisson if ε, σ and μ are constant within the human community (the homogeneous case) but overdispersed if R_0, σ or μ vary within different segments of the population (heterogeneity in immunological responsiveness or exposure to infection). Although crude parameter estimates are available for Λ (from studies of reinfection following chemotherapeutic treatment) and μ, little is known about the possible values of ε and σ for the major helminth infections of man. However, the equilibrium/age-intensity curves generated by the model for various plausible values of ε and σ are similar to observed patterns (Fig. 1*a*–*d*). The model can mimic a range of patterns including: monotonic increase in $M(a)$ to a stable plateau; $M(a)$ peaking within childhood, teenage and early adult age groups, and then declining; and damped oscillations in intensity (Fig. 1*a*–*d*). For a fixed severity of the acquired response (ε), the worm burden curve tends to be convex if memory is long,

and/or transmission is intense, and/or worm life expectancy is long. The age at which a maximum worm load is attained depends primarily on the life expectancy of the worm ($1/\mu$) and the severity of acquired immunological response (ε). Certain of these predictions are in qualitative agreement with observed trends: a decline in $M(a)$ in older age groups is more apparent in areas of intense transmission (Fig. 1*a*, *b*). The damped oscillations in mean worm burden that can be produced within individuals under appropriate circumstances derive from essentially the same mechanisms that can produce oscillations in the incidence of microparasitic infections, such as measles, within populations[23].

Observed distributions of parasite number per person are invariably highly aggregated, with most people harbouring few worms and a few people harbouring most parasites (often 70% of the worms are harboured by <10% of the community)[5,8,9,21,22]. For certain helminths, these 'wormy' people seem to be predisposed to this state by as yet undetermined genetic, behavioural or social factors[8,9]. Under the assumption that predisposition to heavy (or light) infection is primarily under genetic[24–28] (via the immune system) or behavioural control, our model can be extended to encompass variability in the way different groups of individuals within a community either respond to parasitic invasion (different values of the parameters ε, σ and μ) or are exposed to infection (different values of Λ).

The range of patterns generated by such 'heterogeneous models' is bewilderingly large. Here, we simply focus on a model with two types of people; namely, high responders (resistive individuals who harbour low burdens) and low responders ('wormy' people). Figure 2 indicates a range of possible patterns for the change in intensity of infection with age. Heterogeneity between the two groups generates aggregation of parasite numbers within the total population, as measured inversely by the negative binomial dispersion parameter, k (Fig. 2*a*). Heterogeneity in exposure to infection (Λ), via its interaction with the rate of acquisition of immunity, can generate age-related changes in the degree of parasite contagion within age classes; these patterns are similar to observed trends (Fig. 2*a*, *b*). Oscillatory changes in worm load with age in high responders can be masked within the overall average burden if low responders predominate and, conversely, the severity of infection within 'wormy' people may be hidden by the overall average if high responders predominate (Fig. 2*c*, *d*). Therefore, average measures may hide interesting age-related trends in individuals predisposed to heavy or light infection. Such trends, if observable (by longitudinal studies of individual patients), could provide valuable insights into the nature of herd immunity to helminth infection.

The dynamics of naturally acquired immunity have important implications for control programmes. Repeated mass chemotherapy at a level less than that required to eradicate the parasites can significantly reduce the level of herd immunity and can raise average worm burdens in the older age classes above the levels pertaining before control (Fig. 3*a*). This trend will be most apparent if strong, long-lasting immunity is acquired (where σ is small and ε large) in areas where transmission is intense (especially relevant to schistosome and filarial infections). This danger can be avoided by targeting drug treatment to those predisposed to heavy infection (see, for example, Fig. 3*b*). Although helpful for community-based chemotherapy, predisposition to heavy infection as a consequence of poor immunological competence may present serious problems for parasite control by vaccination (if and when vaccines become available). A vaccine must be able to convert low responders (wormy people) into high responders if vaccination on a community scale is to be successful.

The model is a crude approximation to the true complexity of acquired immunity to helminths. Although it generates various epidemiological patterns that are similar to those actually observed, predictions must remain tentative; the main purpose of theoretical analysis is to highlight some of the possible population-level implications of acquired immunity to helminth infection. In particular, the model indicates how valuable insights may be gained from longitudinal epidemiological studies of fluctuations in parasite load within individual patients[10–16] and from experimental studies of long-term continual infection in laboratory animals, described in the accompanying paper[19].

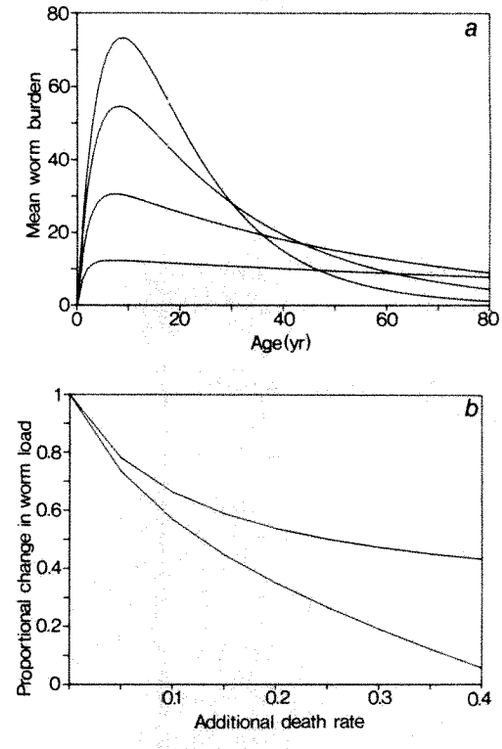

Fig. 3 Impact of chemotherapy on the intensity of infection. ***a***, Homogeneous population (with respect to immunological responsiveness and exposure to infection) in which drug treatment is applied randomly (independent of parasite load) and repeatedly. The four curves denote the equilibrium/age-intensity profile for the precontrol situation (curve 1, at age 10) and three levels of drug application which increase the overall death rate of the parasite within the population from $\mu = 0.25$ (precontrol) to $\mu = 0.33$ (curve 2, at age 10), $\mu = 0.5$ (curve 3, at age 10) and $\mu = 0.75$ (curve 4, at age 10). Parameter values: $\Lambda(\mu) = (\sigma + b)(b + \mu)[R_0 - 1]$, $b = 1/70$, μ = variable, $\varepsilon = 0.0005$, $\sigma = 0.00001$, $R_0 = 1.44$ (when $\mu = 0.75$), $R_0 = 2.13$ (when $\mu = 0.5$), $R_0 = 3.19$ (when $\mu = 0.33$) and $R_0 = 4.16$ (when $\mu = 0.25$). ***b***, Proportional change at equilibrium (over that pertaining before control) in the overall population worm load, $\bar{M}$ (over all age classes and all types of individual) in a population subject to varying degrees of treatment targeted at a 'wormy' fraction ($f_1 = 0.1$). The non-wormy people ($f_2 = 0.9$) are untreated. The value of $\bar{M}$ was calculated from the equation

$$1 = \frac{f_1 R_{01}(b+\sigma_1)}{[(b+\sigma_1)+\varepsilon_1 R_{01}\bar{M}]} + \frac{f_2 R_{02}(b+\sigma_2)}{[(b+\sigma_2)+\varepsilon_2 R_{02}\bar{M}]}$$

where $b = 1/70$, $\varepsilon_1 = 0.00001$, $\varepsilon_2 = 0.0075$, $\sigma_1 = \sigma_2 = 0.1$, $\mu_1 = 0.2$, $\mu_2 = 0.6$, $R_{01} = 4.67$, $R_{02} = 1.63$. Horizontal axis denotes the extra death rate (above the precontrol value of μ_1 and μ_2) resulting from mass chemotherapy. Curve 1 denotes the result of targeting in which only a fraction ($f_1 = 0.1$) are treated (the wormy people with a low ε_1 value, a low parasite death rate (μ_1) and a high parasite basic reproductive rate (R_{01}). Curve 2 denotes mass treatment of the entire population. Note that for an additional death rate of 0.3 per yr (on μ_1 in the case of targeted treatment, and on μ_1 and μ_2 in the case of mass application) the selective treatment of 10% of the population gives a reduction in average worm load ($\bar{M}$) to ~50% (curve 1). By treating the entire population, only an additional 30% change is attained (curve 2).

Differential activity of maternally and paternally derived chromosome regions in mice

B. M. Cattanach & M. Kirk

MRC Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD, UK

Although both parental sexes contribute equivalent genetic information to the zygote, in mammals this information is not necessarily functionally equivalent. Diploid parthenotes possessing two maternal genomes are generally inviable[1], embryos possessing two paternal genomes in man may form hydatidiform moles[2], and nuclear transplantation experiments in mice have shown that both parental genomes are necessary for complete embryogenesis[3–6]. Not all of the genome is involved in these parental effects, however, because zygotes with maternal or paternal disomy for chromosomes 1, 4, 5, 9, 13, 14 and 15 of the mouse survive normally[7,8]. On the other hand, only the maternal X chromosome is active in mouse extraembryonic membranes[9], maternal disomy 6 is lethal[7], while non-complementation of maternal duplication/paternal deficiency or its reciprocal for regions of chromosome 2, 8 and 17 has been recognized[10–12]. We report that animals with maternal duplication/paternal deficiency and its reciprocal for each of two particular chromosome regions show anomalous phenotypes which depart from normal in opposite directions, suggesting a differential functioning of gene loci within these regions. A further example of non-complementation lethality is also reported.

The first set of opposite phenotypes was found in mice disomic for chromosome 11. These were produced, together with animals with disomy 13, by intercrossing heterozygotes for the robertsonian translocation, Rb(11.13)4Bnr, which typically exhibit high levels of non-disjunction of chromosomes 11 and 13 (ref. 13) (Fig. 1). Disomy 13 mice appeared normal in all respects, like other disomics previously produced[7,8], but disomy 11 mice were found to differ markedly in size from their sibs; significantly, when their chromosomes 11 were of maternal origin they were consistently smaller than their littermates, and when their chromosomes 11 were of paternal origin they were consistently larger. This was true for both sexes. The phenomenon was most evident within a few hours of birth (Fig. 2), although the size differences present at birth (ratio of weights, 0.606 ± 0.015 g, $n = 40$, and 1.408 ± 0.036 g, $n = 36$) usually persist to adulthood (small ♀♀, 0.576 ± 0.036 g, $n = 11$; small ♂♂, 0.627 ±

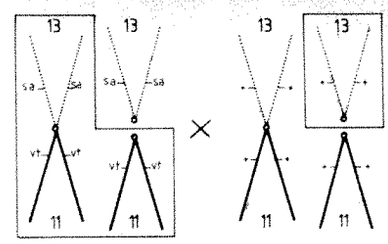

Fig. 1 Production and detection of disomy 11 and 13. Heterozygotes for the robertsonian translocation, Rb(11.13)4Bnr, exhibit high levels of non-disjunction of chromosomes 11 and 13. When intercrossed, normal disjunction in both parents results in the production of chromosomally balanced young; with non-disjunction in one parent, monosomy and trisomy for chromosomes 11 and/or 13 result; but when non-disjunction occurs in both parents and complementary products (as illustrated) unite, chromosomally balanced young disomic for chromosomes 11 (as shown) or 13 are produced. These are most readily detected when one parent is homozygous for a gene marker; marked young are then either maternal or paternal disomics according to which parent carries the marker. Disomy 11 is detected in this way with a frequency of about 1-2%[16] using the gene marker vestigial tail (*vt*). It has also been found with a dominant marker, Wavy coat (Re^{wc}). Marked maternal disomics are smaller than their sibs, marked paternal disomics are larger. Most unmarked young are of normal chromosome origin but unmarked disomic young are also found; in crosses producing large paternal disomy 11 progeny, small maternal disomy 11 young may also occur (*x* and *y*, Fig. 2) and their genotype can be confirmed by breeding tests. The reverse is also true. The size phenomenon is not therefore dependent on the marker genes present. In the same crosses, satin (*sa*) was the marker for detecting disomy 13.

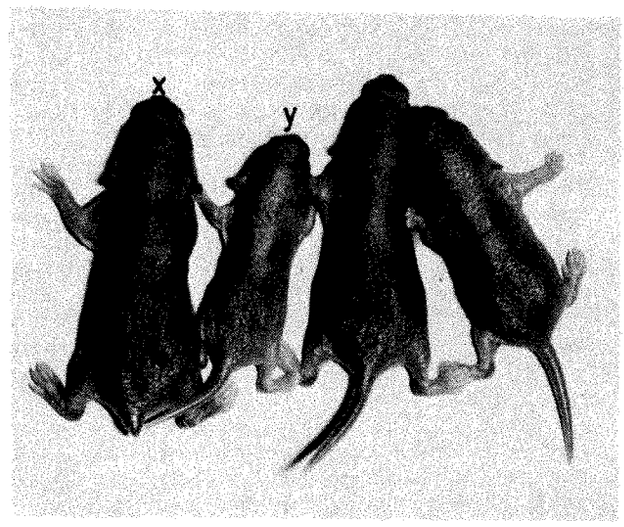

Fig. 2 Maternal and paternal disomy 11 in a single litter. Litter from an unmarked Rb4Bnr female heterozygote sired by a *vt* marked Rb4Bnr male heterozygote. The *vt* marked paternal disomic (*x*) is large, whereas one marked sib is clearly small (*y*). Breeding tests on such small animals show that most are not heterozygous for *vt*, but rather homozygous wild type and therefore maternal disomics. The reverse situation also occurs. Marked and unmarked disomics occur with near-equal frequencies, although seldom, as here, within single litters.

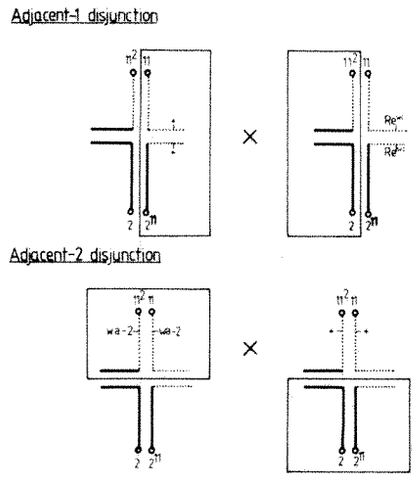

Fig. 3 Intercrosses of T(2; 11)30H heterozygotes. Alternate segregation in both parents leads to the production of chromosomally balanced young; adjacent-1 or adjacent-2 disjunction in one parent leads to the production of young with unbalanced, duplication/deficiency chromosomal constitutions. However, when adjacent-1 disjunction occurs in both parents and complementary products (as illustrated) unite, chromosomally balanced young appear which are either maternal duplication/paternal deficiency or maternal deficiency/paternal duplication for the distal region of chromosome 11 (and vice versa for chromosome 2). These can readily be detected when one parent is homozygous for a gene marking this chromosome region, Re^{wc}, in the present experiments. Each of the two duplication/deficiency types occurs with a frequency of about 11–14% ($n = 514$). When adjacent-2 disjunction occurs in both parents and complementary products (as illustrated) unite, chromosomally balanced young which are either maternal duplication/paternal deficiency or maternal deficiency/paternal duplication for the proximal region of chromosome 11 (and vice versa for chromosome 2) should be produced. These should be detectable with a proximal 11 chromosome marker, waved-2 (*wa-2*), in the present experiments. When the female parent carried the marker, *wa-2* progeny representing maternal duplication/paternal deficiency for proximal 11 were detected with a frequency of ~1.3% (2/153 classified for *wa-2* at 10 days of age); all were small like maternal disomy 11. No large unmarked young which could have represented maternal deficiency/paternal duplication for proximal 11 were detected, however, and, consistent with this, no *wa-2* progeny were recovered (0/248) from intercrosses in which the male parent carried the marker. The genotype may therefore be lethal (see text). However, small, unmarked young which proved to be maternal duplication/paternal deficiency types by breeding tests were recovered from the latter cross (3/248).

0.045 g, $n = 19$; large ♀♀, 1.328 ± 0.020 g, $n = 15$; but for large ♂♂, 1.234 ± 0.036 g, $n = 14$).

The large and small disomics were proportionately normal in all respects, they exhibited no viability problems and both sexes were fertile. The size differences did not persist into the next generation; the progeny of both large and small disomics of each sex and those of control Rb4Bnr heterozygotes were all of similar weight at birth and at 3 weeks of age. The absence of any indication of a maternal effect on progeny size may be attributed to the small litter sizes in all crosses, resulting from the high rates of translocation-associated non-disjunction.

Intercrosses between mice heterozygous for the reciprocal translocation, T(2; 11)30H, provided evidence that only the proximal region of chromosome 11 (proximal 11) was associated with the size phenomenon (Fig. 3). Neither maternal duplication/paternal deficiency for distal 11, nor the reciprocal, resulted in mice which were of abnormal size at birth. However, maternal duplication/paternal deficiency for proximal 11 resulted in mice which were small in size both at birth and subsequently, resembling maternal disomy 11 in all respects. No young representing maternal deficiency/paternal duplication for proximal 11 have been found and it seems probable that this genotype is lethal.

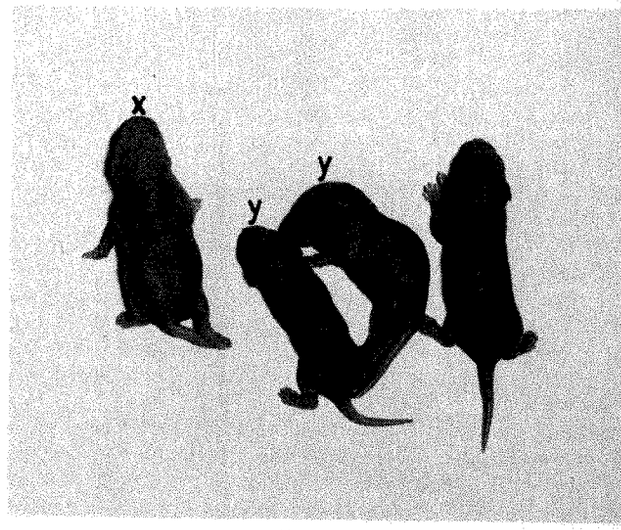

Fig. 4 Anomalous young produced from T(2; 11)30H intercrosses. *x*, Phenotype characterizing maternal deficiency/paternal duplication for the distal region of chromosome 2; *y*, phenotype characterizing maternal duplication/paternal deficiency for this region (see text).

As paternal disomy 11 is viable, the lethality may be reasonably attributed to the chromosome 2 constitution (maternal duplication/paternal deficiency for proximal 2) and represent a further example of the non-complementation phenomenon described by Searle and Beechey[10].

The second set of opposite phenotypes was derived from the T30H crosses. Although both maternal duplication/paternal deficiency for distal 11 and its reciprocal were detected, both genotypes proved to be postnatal lethals. Again, because both maternal and paternal disomy 11 are viable, the lethality may be attributed to the chromosome 2 constitutions, namely, maternal deficiency/paternal duplication for distal 2 and its reciprocal. A lethality for maternal duplication/paternal deficiency for this region of chromosome 2 has been reported previously[10], but a characteristic phenotype can now be described. Such mice have long flat-sided bodies with arched backs (Fig. 4). More strikingly, they become almost totally inactive within a few hours of birth and are killed by their mothers. Very few survive more than 24 h. A remarkable finding was that the reciprocal type, maternal deficiency/paternal duplication for distal 2, shows an effectively opposite phenotype. These mice have short square bodies with broad flat backs (Fig. 4) and are notably hyperkinetic. They usually survive for several days but fail to grow normally, and their behaviour becomes increasingly extreme, tremor and balance defects appearing frequently.

Because the anomalous phenotypes associated with maternal and paternal disomy 11 and corresponding types of duplication/deficiency for distal 2 can each occur among the progeny of single crosses, maternal cytoplasmic effects cannot be responsible for the abnormalities. Rather, a differential functioning of maternal and paternal chromosomes or chromosome regions is indicated, which suggests the existence of a form of chromosome imprinting[14,15] that affects gene activity. The contrasting phenotypes (small and large; hypokinetic and hyperkinetic) depart from the normal in opposite directions and this suggests excess versus shortage of gene activity. This could mean either single or earlier activity of the paternal chromosome regions in the cases cited, and inactivity or later activity of the corresponding maternal regions. Paternal duplication would then give excess/earlier activity and the reciprocal subnormal/later activity. The X-inactivation process[16] provides precedence for the activity of only one parental chromosome or chromosome

region[17]; precedence for an earlier activity of one chromosome or chromosome region over its homologue has not been found, but has been reported at the gene locus level in diverse species and inter-family hybrids, including the mouse[18–23].

The phenomena described could, of course, result from the differential regulation of single loci in the chromosome regions concerned. The size phenomena associated with proximal 11 might involve a growth hormone gene such as Ames dwarf (*df*)[24], which lies in this chromosome region. The *df* mutant is of normal size at birth despite a severe deficiency of pituitary hormones[25], but the homologous chromosome region in man[26] carries a cluster of growth hormone loci[27], and at least one of these acts in the placenta. Hormonal control of fetal growth mediated through the placenta is therefore suggested. For distal 2, the behavioural problems of the anomalous mice may mean they have neurological defects; therefore, the *wst* locus[28] may be involved.

Single or preferential activation of regulator loci or of receptor loci, to give the latter different affinities for regulator substances, may underlie the phenomenon presented here, and detailed studies of the anomalous mice may provide some answers. An interaction between loci in different chromosome regions is a further possibility and studies with translocations having other breakpoints in chromosomes 2 and 11 could be informative here. Whatever the mechanism operating, it may well be the basis of the non-complementation lethality phenomenon[10] and the lethality manifested by parthenogenic and androgenic embryos[1–6].

Since submission of this paper, it has been reported that an 180-base-pair DNA sequence thought to control pattern formation in early development, a homoeo box, is located on human chromosome 17 and mouse chromosome 11 (refs 29, 30) and therefore in the chromosome region responsible for the size phenomena described here. Another homoeo box has been located on chromosome 6 (ref. 31), which exhibits non-complementation lethality[7]. The occurrence of homoeo boxes in chromosomes which show differential activity according to parental origin could be fortuitous, but the association suggests a functional relationship. If true, homoeo boxes should also be found on chromosomes which show the parental origin phenomenon (2, 8 and 17), but perhaps not on those which do not (1, 4, 5, 9, 13, 14 and 15).

Substance P raises neuronal membrane excitability by reducing inward rectification

P. R. Stanfield*, Yasuko Nakajima† & Kazuhiko Yamaguchi

Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907, USA

Much interest has recently centred on the properties of peptides that modulate the excitability of nerve cells. Such compounds include the undecapeptide substance P, which is particularly well established as an excitatory neurotransmitter[1,2], and we examine here its effects on magnocellular cholinergic neurones taken from the medial and ventral aspects of the globus pallidus of newborn rats and grown in dissociated culture[3]. These neurones have previously been shown to respond to substance P[3] and are analogous to the nucleus basalis of Meynert in man[4,5], which gives a diffuse projection to the cerebral cortex and whose degeneration is the likely cause of Alzheimer's disease[5]. Substance P depolarizes these cultured neurones by reducing an inwardly rectifying potassium conductance; this conductance has been found in several neuronal types[6–9] and has similar properties to those of certain other cells[10–13]. As discussed below, modulation of inward (or anomalous) rectification by substance P implies a self-reinforcing element to the depolarization caused by the peptide.

Neurones grown from 10 days to 3 weeks in culture were examined under whole cell recording[14,15] (for details, see Fig. 1 legend). When substance P (3 μM) was pressure ejected onto neurones examined in constant current conditions, a depolarization was produced (Fig. 1*a*) which lasted for 15 s to ≥5 min. Its amplitude was rarely as large as shown in Fig. 1*a*, but generally exceeded 1–2 mV. As described previously, this depolarization was associated with a fall in membrane conductance (for example, refs 16, 17), but in the cells examined in the present study, the fall in conductance was seen more clearly if the membrane was hyperpolarized (Figs 1*b*, 2*a*), implying that inward rectification[6–13] is the conductance affected.

In establishing that inward rectification is modulated, we have sought to satisfy three criteria; first, that a K^+ conductance with an inwardly rectifying current voltage relation is reduced; second, that the conductance depends on external K^+ concentration as well as on voltage[11–13,18]; and third, that the conductance mechanism is nearly impermeable to rubidium (refs 10, 12, 19), which should therefore abolish the response to substance P.

The nature of the response to substance P is illustrated in the current–voltage relations of Fig. 2*b*. The substance P-sensitive current reversed its polarity close to E_K, the equilibrium potential for K^+, reversal changing from -98.0 ± 1.9 mV ($n = 6$) to $-85.4 + 1.3$ mV ($n = 14$) to -57.9 ± 1.6 mV ($n = 7$) as external K^+ was changed from 2.5 to 5.0 to 12.5 mM (internal K^+, 128 mM).

Although it remains possible that conductances other than inward rectification are affected, neither the transient A-current[20] (Fig. 2*a*) nor the delayed K^+-current seem to be involved in the response of these cells. As Ca^{2+}-activated K^+ currents also become activated under depolarization[21,22], rather than under hyperpolarization as here, their involvement is unlikely. In addition, in our experiments internal Ca^{2+} was buffered to 10^{-7} M. The M-current, which is known to be involved in the response to substance P in certain cells[23], was not seen in the conditions of our experiments.

Our experimental external solutions contained tetrodotoxin (TTX, 1 μM) to block Na^+ currents, and blockage of Ca^{2+} currents with cadmium (0.5 mM, two cells) did not alter the response. Hence, the shape of the substance P-sensitive current-

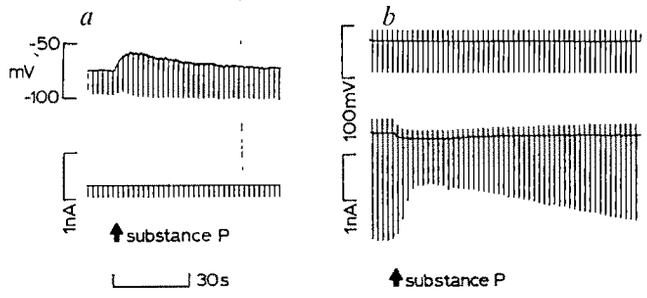

Fig. 1 Depolarization (*a*) and change in membrane current (*b*), measured under voltage clamp, resulting from application of 3 μM substance P to a neurone cultured from the magnocellular basal forebrain of a newborn rat The cell had been grown for 11 days in modified Eagle's medium with Earle's salt at 37 °C in a 10% CO_2 atmosphere. The methods of isolation, dissociation and culture have been briefly described previously[3], a detailed account of the methods will be published elsewhere. The initial resting potential of the cell was −65 mV; soma diameter, 28 μm, temperature, 31.2 °C. In *a*, a steady current of −75 pA was applied, which took the resting potential to approximately −75 mV; current pulses were −240 pA in amplitude and 100 ms long. In *b*, the holding potential was −76 mV The depolarizing pulse was 20 mV in amplitude and the hyperpolarization, 60 mV. Both were 100 ms long. E_K, measured from the substance P response, was −89 mV. Whole cell recording was used[14,15]. Recording pipettes were made from Blue Tip microhaematocrit capillary, and their tips were fire-polished but uncoated[14] The pipette used in the experiment shown here had a resistance of 3.0 MΩ. The pipette (intracellular) solution contained (mM)[15]. K-aspartate, 120; NaCl, 40; $MgCl_2$, 3; $CaCl_2$, 0.25 and EGTA, 0 5 (calculated ionized Ca^{2+}, 10^{-7} M); HEPES/KOH buffer, 5; Na_2ATP (vanadate-free), 2. The *p*H of this solution was adjusted to 7.2 with KOH. External solution (mM)· KCl, 5; NaCl, 145.5, $CaCl_2$, 2.4; $MgCl_2$, 1 3, (+)glucose, 11; HEPES/NaOH buffer (*p*H 7 4), 5. Internal and external solutions were designed to have the same osmolarity (~310 mosmol). The recording amplifier was a List electronic type EPC 7 patch clamp, and currents were filtered at 3 kHz, using the filter of this amplifier. Records of current, voltage and timing of substance P application were stored on a Hewlett-Packard 3520B tape recorder for later analysis Voltage commands were provided from the gated output of a Digitimer type D4030, divided appropriately. Application of substance P was made by pressure ejection. A pipette, tip diameter 5 μm, was filled with external solution containing substance P at 3 μM Timed pressure pulses (~0.2 p.s.i and 1 63 s long) ejected this solution onto the cell. To avoid excessive depolarization of neurites by substance P, this pipette was placed close to the soma of the neurone. In this experiment the distance was 12.8 μm from the edge of the soma, and single 'puffs' of substance P were applied at the times indicated by arrows.

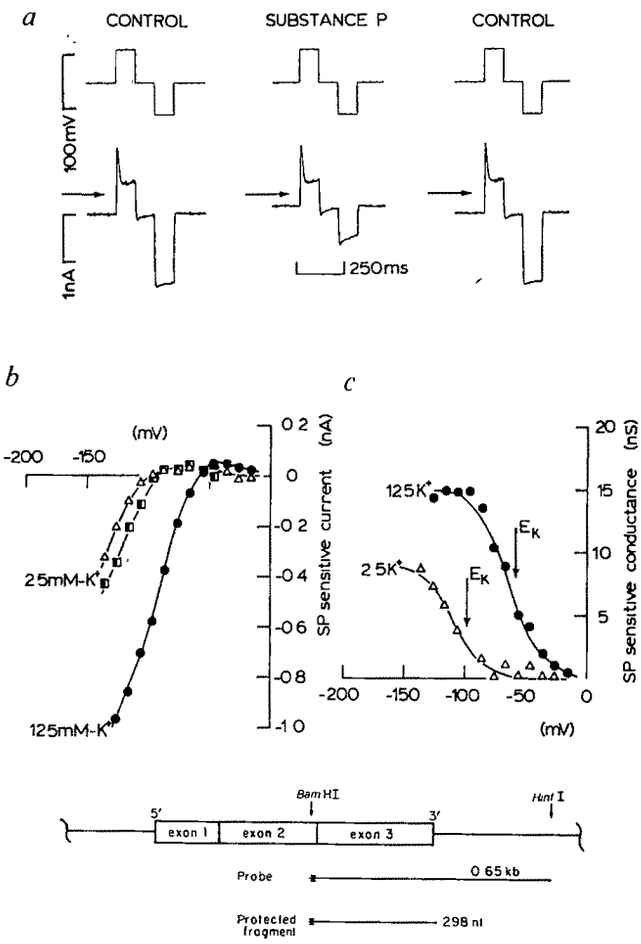

Fig. 2 *a*, Records of membrane potential (mp) (above) and membrane current (below) in 12.5 mM K^+ obtained before, during and after recovery from application of 3 μM substance P Holding potential, −76 mV, voltage steps depolarize and hyperpolarize by 60 mV for 100 ms. The pulses were applied 100 ms apart Horizontal arrows indicate the zero current level Note that the A-current is activated by depolarization, but is unaffected by substance P Inward currents are substantially reduced, and substance P seems to increase the rate of inactivation of these inward currents under hyperpolarization Three puffs (each 1 63 s long) were applied in rapid succession to produce a brief plateau in the response to the peptide, during this time a membrane current–voltage relation was measured with pulse pairs whose amplitude increased in 10-mV steps from ±10 to ±60 mV This procedure took 6 s to complete. *b*, Current–voltage relations from the same cell as in *a*, measured first in 2.5 mM (△), then 12.5 mM (●), then in 2 5 mM K^+ (◨). The current plotted is the substance P-sensitive current, measured by subtracting the current at the end of the 100-ms voltage steps applied during the action of substance P from the average of the control currents measured before and after recovery from substance P application During the final run in 2 5 mM K^+, no control was measured after substance P application, owing to breakdown of the seal between the recording pipette and the cell The initial resting potential of the cell was −77 mV, diameter of cell soma, 26 μm, temperature, 29.2 °C. In 2 5 mM K^+ solution, NaCl concentration was 148 mM, and in 12 5 mM K^+ it was 138 mM, otherwise the external solution had the composition given in Fig. 1 legend Ordinate, substance P-sensitive membrane current (nA), abscissa, membrane potential (mV). *c*, Chord conductance for the substance P-sensitive current The currents in 2 5 mM K^+ (△) and 12.5 mM K^+ (●) are divided by the driving force on K^+ ($V-E_K$, where E_K is measured from the reversal potential of the substance P-sensitive current–voltage relations) The relations are fitted by Boltzmann expressions, according to

$$g_K = \bar{g}_K\{1+\exp[(V-\bar{V})/k]\}^{-1}$$

where g_K is potassium conductance, $\bar{g}_K$ is limiting potassium conductance, $\bar{V}$ is the voltage at which $g_K = \bar{g}_K/2$, and k determines the steepness of the curve. For 2.5 mM K^+ $\bar{g}_K = 9.0$ nS; $\bar{V} = -109$ mV and $k = 11\ 5$ mV For 12.5 mM K^+, $\bar{g}_K = 15\ 0$ nS; $\bar{V} = -62$ mV and $k = 13\ 8$ mV. Inward rectification of egg cells[10] and skeletal muscle[18] has previously been fitted to an expression similar to the above equation, with a similar steepness for voltage dependence, and an approximately similar increase in $\bar{g}_K$ with $[K^+]_o$ The measured E_K (indicated by vertical arrows) shifts by 40 mV when $[K^+]_o$ is increased from 2 5 to 12 5 mM (theoretical, 42 mV), $\bar{V}$ shifts by 47 mV, close to the shift in E_K Ordinate, substance P-sensitive chord conductance (nS); abscissa, membrane potential (mV)

voltage relation is not influenced by altered activation of inward Na^+ or Ca^{2+} currents under depolarization.

The neurones we used possess long neurites whose membrane potential will not be fully controlled by the voltage clamp. Because this problem will affect the amount of membrane current we record, we minimized excitation of neurites by substance P by applying the peptide close to the cell body. We also attempted to test whether lack of complete control of neurites influences the shape of the relation between substance P-sensitive membrane current and membrane potential by applying tetraethylammonium ions (TEA^+, 50 mM), which reduce membrane potassium conductance[24] and may therefore be expected to alter voltage decrements along neurites. TEA^+ reduced the size of the response to substance P, but had no effect on the shape of the current–voltage relation (Fig 3*b*).

The second criterion for the dependence of the conductance on both external K^+ and voltage was demonstrated by measuring the response in the same cell in 2.5, 12.5 and 2.5 mM K^+ (Fig. 2). The dependence on external K^+ concentration ($[K^+]_o$) is seen more clearly if the K-chord conductance is computed (by dividing the substance P-sensitive membrane current by the driving force on K^+) and plotted against membrane potential (Fig. 2*c*). The relationship between conductance and potential was shifted

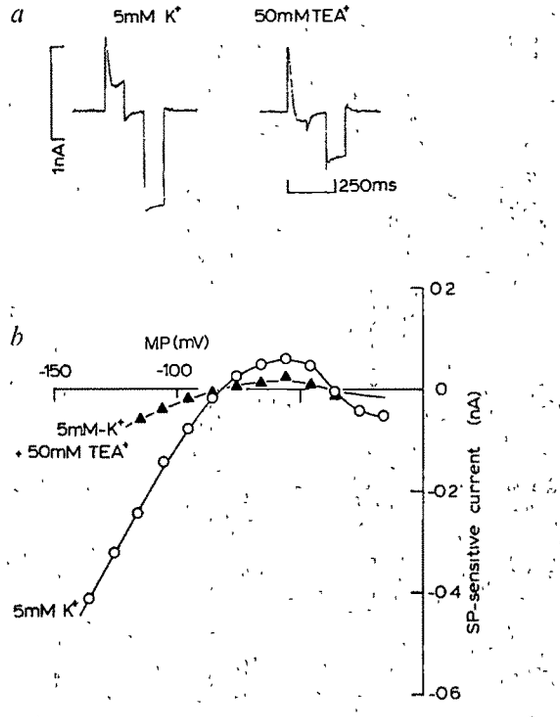

Fig. 3 *a*, Records of membrane current made under 50 mV depolarizations and hyperpolarizations from the holding potential of −76 mV, in a cell immersed successively in 5 mM K^+ solution and 5 mM K^+ + 50 mM TEA^+ solution. This concentration of TEA^+ leaves the A-current virtually unaffected, but abolishes delayed K^+ currents recorded under depolarization. Inward rectification is reduced, as indicated by the reduction in inward current under hyperpolarization and by the reduced response to substance P (*b*). *b*, Substance P-sensitive current (measured as described in Fig. 2 legend, but at the start of the voltage step) plotted against membrane potential in 5 mM K^+ (○) and 5 mM K^+ + 50 mM TEA^+ solution (▲). The TEA^+ solution contained 96 mM NaCl. The line to the TEA^+ results is that to the open circles, multiplied by 0.26, indicating that the form of the current–voltage relation is not altered by TEA^+, even though the current amplitude is reduced. Cell resting potential, −70 mV; diameter of cell soma, 24 μm; temperature, 29.9 °C; diameter of substance P pipettes, 5 μm; distance from cell, 12.8 μm; resistance of recording pipette, 3.0 MΩ.

to more positive levels at higher $[K^+]_o$, a property characteristic of inward rectification[11,13].

The third criterion that distinguishes inward rectification from certain other classes of K^+ conductance is its low permeability to Rb^+ (refs 10, 12, 19). Figure 4 shows that replacement of external K^+ by Rb^+ blocks inward rectification, reducing the membrane current that flows at potentials negative and slightly positive to the resting potential. Evidently, Rb^+ is itself impermeant and acts to block efflux of K^+ through the inward rectifier. The substance P-sensitive conductance of this cell had a current–voltage relation similar to that blocked by Rb^+, and Rb^+ abolished the response to substance P (Fig. 4*b*,*c*).

We have investigated certain other properties of this substance P-sensitive permeability. It is blocked by the addition of external Cs^+ (2 mM), as are other inward rectifiers[8,25–27]; it persists in the absence of external Na^+ (tetramethylammonium replacement), unlike that reported in hippocampal neurones[9]; it also persists in the absence of internal Na^+, whose replacement with K^+ does not abolish the response to substance P. This property (and its sensitivity to TEA^+ reported above) is shared with inward rectification of skeletal muscle[18,28], but not with that of egg cells, which is abolished in the absence of internal Na^+ (ref. 11).

Our results with substance P on magnocellular basal forebrain neurones of the rat are reminiscent of those obtained with serotonin on *Aplysia* (molluscan) neurones by Benson and Levitan[25]. In *Aplysia*, serotonin enhances inward rectification by phosphorylating the K^+ channels through cyclic AMP-dependent protein kinase. Here substance P reduces inward rectification. Although we have not investigated the steps between the binding of substance P to its receptor and the closure of K^+ channels, it seems likely that an intracellular second messenger system is involved[29], and that this is not washed out during whole cell recording for periods up to 1 h.

Substance P may have several effects on nerve cells. For example, in chromaffin cells, which secrete catecholamines, it acts indirectly, reducing the excitatory response to acetylcholine by increasing the rate of desensitization of nicotinic receptors for that transmitter[30]. In the central cholinergic neurones used in this study, excitability was increased, the more common physiological effect of the peptide[1,2]. As we have shown, this effect is achieved by reducing inward rectification, which contributes substantially to the resting membrane conductance (Fig. 4). Because this K^+ conductance decreases on depolariz-

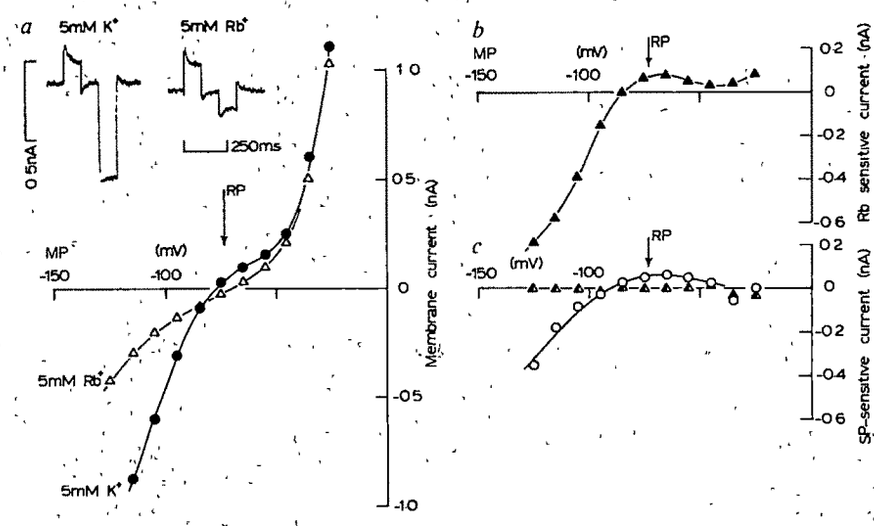

Fig. 4 Rb^+-induced block of inward rectification and of the effect of substance P. *a*, Membrane current–voltage relation obtained by plotting current at the beginning of the 100-ms potential step or at the peak of the A-current, which becomes activated at potentials positive to −50 mV. Currents were recorded in 5 mM K^+ (●) solution and then in 5 mM Rb^+ (zero K^+, △) solutions. These solutions also contained NaCl at 145.5 mM, but were otherwise identical with that listed in Fig. 1 legend. The vertical arrow denotes the resting potential (RP) of the cell (−74 mV) recorded immediately after sealing the recording pipette onto the cell and breaking the membrane patch for whole cell recording. The inset shows membrane currents obtained in response to 30 mV depolarizations and hyperpolarizations from the holding potential (−76 mV) in 5 mM K^+ and 5 mM Rb^+ solutions, 3.3 MΩ; diameter of cell soma, 24 μm; temperature, 30.3 °C. Ordinate, membrane current (nA); abscissa, membrane potential (mV). *b*, Membrane current removed by Rb^+ substitution. The current–voltage relation was obtained by subtracting the current in 5 mM Rb^+ from that in 5 mM K^+. Arrow denotes initial resting potential of the cell. *c*, Membrane current–voltage relation for the substance P-sensitive current in 5 mM K^+ (○) and in 5 mM Rb^+ (▲) solution. These relations were obtained as in Fig. 2 by subtracting the current during substance P action from the average of currents measured in controls before and after recovery from substance P application. Vertical arrow, initial resting potential of the cell. In this cell, whole cell recording failed during the return to 5 mM K^+ solution. However, we recovered the substance P effect after Rb^+ application in one other cell.

ation and increases as the membrane potential becomes more negative (Fig. 2c), substance P, by reducing K^+ conductance, will induce depolarization and this depolarization will further reduce K^+ conductance. Thus, by modulating inward rectification, substance P (and serotonin in neurones of *Aplysia*) will have a self-reinforcing element to its effect on excitability.

We thank Dr Shigehiro Nakajima for help and discussion. The work was supported by NIH grant NS 10457 (Y.N.) and by a travel grant from the Wellcome Trust (P.R.S.).

Modulation of a transient outward current in serotonergic neurones by α_1-adrenoceptors

G. K. Aghajanian

Departments of Psychiatry and Pharmacology, Yale University School of Medicine and the Abraham Ribicoff Research Facilities of the Connecticut Mental Health Center 34 Park St, New Haven, Connecticut 06508, USA

The excitability of various neurones in the mammalian central nervous system (CNS), ranging from motoneurones to serotonergic neurones, is enhanced by α_1-adrenoceptor agonists[1]. Excitations mediated via α_1-adrenoceptors are associated with a slow depolarization and an increase in input resistance, probably resulting from a decrease in resting potassium conductance[1,2]. However, the involvement of voltage-dependent transient currents in mediating α_1 excitatory effects has not been evaluated. An early transient outward current has been described which is important in regulating the frequency of repetitive firing; it is activated by depolarizing voltage steps from potentials more negative than rest and blocked by 4-aminopyridine[3,4]. This current, which has been termed 'I_A', was found originally in invertebrates[3,4] and subsequently in various vertebrate neurones[5-8]. The present single-electrode voltage-clamp study demonstrates an early transient outward current (I_A) in serotonergic neurones which is suppressed by noradrenaline and the α_1-agonist phenylephrine; a suppression of I_A may account in part for the acceleration of pacemaker activity induced by α_1-agonists in serotonergic neurones.

Rat serotonergic dorsal raphe neurones, investigated in voltage-clamp conditions (see Fig. 1 legend), exhibited an early transient outward current with the characteristics of I_A as originally described in molluscan neurones[3,4]. This current could be evoked by depolarizations from holding potentials below resting potential and suppressed by 4-aminopyridine (4-AP; $n = 5$) (Fig. 1); in unclamped cells in the absence of tetrodotoxin (TTX), 4-AP (1 mM) produced a marked activation of firing

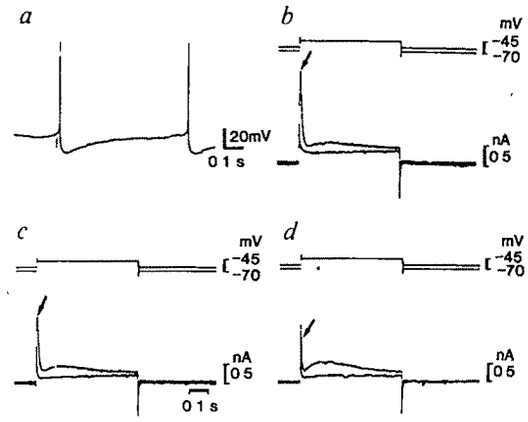

Fig. 1 A transient outward current in a serotonergic neurone and its suppression by 4-aminopyridine (4-AP). *a*, Spontaneous spikes of a typical serotonergic neurone in the dorsal raphe slice preparation; note the large AHPs, followed by a rapid phase of depolarization and then a plateau period before the subsequent spike. In *b*, the slice has been perfused with TTX (1 μM) to eliminate sodium spikes and the cell has been voltage clamped at −70 mV (holding current, −0.01 nA); a step depolarization to −45 mV elicits a transient outward current (arrow) which peaks approximately 8 ms after the depolarizing step; a superimposed trace shows the virtual absence of a transient outward current when the holding potential is −60 mV rather than −70 mV. In *c*, 10 min after the addition of 1 mM 4-AP to the perfusate, the transient outward current (arrow) is reduced by ~30% (leakage current was estimated by subtraction of instantaneous current after the −60 to −45 mV step). In *d*, 12 min after the 4-AP has been increased to 2 5 nM, the transient outward current (arrow) is reduced by more than 60%. In *b* and *c* the current traces are beneath the voltage traces; outward currents are upward going Photographs were taken on line from a storage oscilloscope.

Methods. Coronal midbrain slices (300-350 μm) through the dorsal raphe nucleus were obtained from 53 male albino rats (125-200 g; Charles River). As described previously[18], slices were placed on a lens paper strip at the fluid-gas interface of a slice chamber; the temperature was kept at 33 ± 0.5 °C. Artificial CSF, gassed with 95% O_2/5% CO_2 to give a final *p*H of 7.37-7.4, was composed of (in mM). NaCl, 130; KCl, 5.0; $CaCl_2$, 2.0; $MgSO_4$, 2.0, $NaHCO_3$, 25.7; NaH_2PO_4, 1 25; (+)glucose, 15. Drugs were administered in known concentrations in the perfusate; ascorbic acid (0.1 mM) was added to solutions of noradrenaline to retard oxidation. There was a continuous flow of humidified 95% O_2/5% CO_2 through the chamber. To facilitate the flow of fluid over the tissue, slices were covered with a monolayer of cotton gauze. To minimize capacitance and resistance, short stubby electrodes (7-8 mm, shank to tip; 30-50 MΩ) were pulled with a Brown-Flaming puller (Sutter Institute) using Microstar tubing (1.4 mm; Radnoti Glass Inc.); filling was with 2 M KCl. Intracellular recording and single-electrode voltage clamping were conducted using an Axoclamp-2 voltage clamp (Axon Instruments); electrode settling time was within 50-75 μs, allowing switching frequencies of 4-6 kHz and a loop gain of at least 5 nA mV^{-1} (30% duty cycle). Although phase lag was used (to prevent oscillations), false clamping was avoided by using optimal capacitance neutralization and by selecting a switching frequency which allowed full settling to a horizontal baseline as determined by continuously monitoring input voltage[19]. As an operational criterion of the adequacy of the space clamp, loop gain was increased until high-threshold calcium spikes, induced by step depolarizations, were completely clamped; this was carried out in the presence of TTX (1 μM; Sigma) to block sodium spikes. The dorsal raphe nucleus was visualized by its surface markings in incident light; serotonergic neurones within the dorsal raphe nucleus were identified by their characteristic long-duration action potentials (2 ms), high input resistance (200-400 MΩ), large AHPs, and pacemaker potentials[11,18].

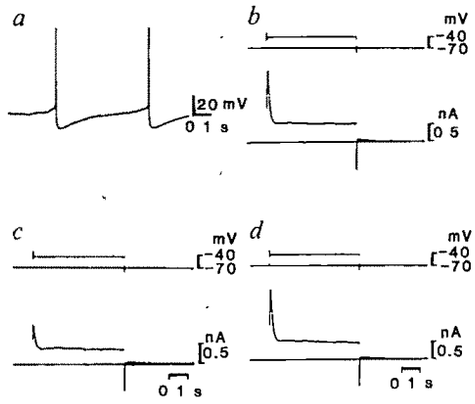

Fig. 2 Suppression by phenylephrine of the transient outward current (I_A) in a serotonergic neurone and the reversal of this effect by prazosin. *a* Shows the spikes of a neurone before clamping and treatment with TTX; this cell was not spontaneously active and spikes were evoked by 0.02 nA of depolarizing current. In *b*, TTX (1 μM) has been added to the perfusate and the cell has been clamped at −70 mV (holding current, −0 01 nA); a step depolarization to −40 mV elicits a typical I_A. As in Fig. 1, leakage current was estimated by holding at −60 mV (where I_A is inactivated; see Fig. 3*e*) and measuring instantaneous current after stepping to −40 mV (trace not shown). In *c*, the amplitude of I_A is markedly reduced after perfusion (15 min) with artificial CSF containing phenylephrine (25 μM); note that the holding current has shifted to −0.07 nA, indicating an increase in resting inward current. Although not readily discernible at this gain and holding potential, there is also a prolongation of the outward tail current (thicker trace) with little or no change in maximal amplitude during phenylephrine administration; this effect was seen consistently for both phenylephrine and noradrenaline. In *d*, 12 min after the addition of prazosin (5 μM) in the continued presence of phenylephrine, there is a total reversal of the suppression in I_A.

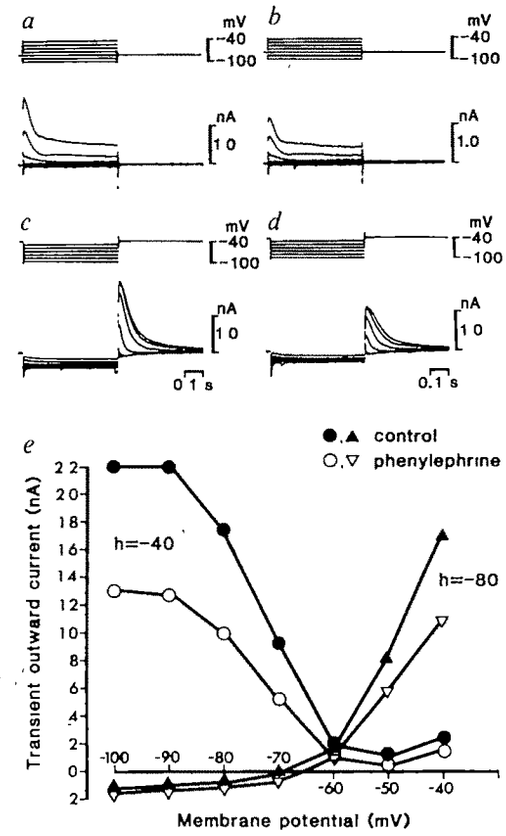

Fig. 3 The effect of phenylephrine on I_A activation/inactivation curves. In *a* and *b*, holding potential (h) is at −80 mV (holding current in *a*, −0 07 nA), current responses (lower traces) are to voltage steps (upper traces) ranging from −40 to −100 mV. Note that I_A first becomes activated at −60 mV and increases progressively up to the −40 mV step. In *b*, the administration of phenylephrine (25 μM; 18 min) results in a decrease in amplitude at each step. In *c* and *d*, the holding potential is at −40 mV (holding current in *c*; +0 25 nA) with hyperpolarizing prepulse steps ranging from −50 to −100 mV; note that I_A is de-inactivated only by hyperpolarizing steps below −60 mV. In *d*, following the administration of phenylephrine (15 min), the holding current shifts to +0 16 nA and there is a reduction in the amplitude of I_A elicited by a return to the holding potential (−40 mV). Note the decrease in leakage current in the prepulse series (−50 to −100 mV) during phenylephrine perfusion as compared with the control series in *c*. In *e*, control and phenylephrine traces for holding potentials of h = −40 mV and h = 80 mV are plotted as direct current-voltage (*I-V*) curves (no leakage current subtraction), as can be seen, at all voltage steps where I_A is activated, phenylephrine reduces the maximum amplitude. Also note that phenylephrine induces a small increase in 'resting' inward current. The slice was perfused with artificial CSF containing TTX (1 μM) throughout the experiment to block sodium spikes.

rate (not shown). A further similarity to I_A is the fact that in artificial cerebrospinal fluid (CSF) containing 5 mM KCl, tail currents of this early transient outward current had a reversal potential of approximately −82 mV (±3 s.d.; n = 4 cells); this shifted to −68 mV (±3 s.d.) in 10 mM KCl, as would be predicted by the Nernst equation for a current carried by potassium ions. Based on these criteria, the early outward current of serotonergic neurones is hereafter designated I_A. To achieve rapid responses, the effects of noradrenaline or phenylephrine on the amplitude of I_A were tested at a concentration of 25 μM, which is approximately 10 times their ED_{50} for activating the firing of serotonergic neurones[11]. Phenylephrine (25 μM) produced a marked reduction in the amplitude of I_A (Fig. 2). For the total group of serotonergic cells tested in this manner, phenylephrine and noradrenaline produced a 38% (±10 s.d.; n = 8) and 34% (±13, s.d., n = 8) reduction in I_A, respectively (leakage current was subtracted as described in Fig. 1 legend); increasing the concentration of phenylephrine or noradrenaline produced little or no further change. Activation/inactivation curves showed that suppressions of I_A by phenylephrine (Fig. 3; n = 5) and noradrenaline (n = 5) were present throughout a wide range of voltages, with initial activation occurring between −60 and −50 mV; in addition, phenylephrine reduced the leakage current (Fig. 3*d*), an effect which corresponds to the increase in input resistance detected by current-clamp methods[1].

The complex time course of current offset (see, for example, Fig. 3*a*, *b*) suggests the presence of transient currents in addition to I_A; these may include rapidly activating Ca^{2+} and Ca^{2+}-dependent potassium currents (I_{Ca} and $I_{K(Ca)}$)[9,10]. To evaluate the possible involvement of Ca^{2+}-dependent currents, the Ca^{2+}-channel blocker cadmium (1 nM) was perfused until an early inward current (arrow, Fig. 4*a*) and a delayed outward current (including an outward tail current; double arrows, Fig. 4*a*) were blocked (Fig. 4*b*); these currents, which were elicited from a holding potential at which I_A is inactivated, presumably represent components of I_{Ca} and $I_{K(Ca)}$, respectively. When I_A was once again evoked, it was found to be undiminished by Cd^{2+}; in these conditions, phenylephrine had its usual suppressant effect (Fig. 4*c*, *d*; n = 4).

Pharmacological studies have indicated that the noradrenergic activation of serotonergic neurones is mediated specifically by an α_1-adrenoceptor[11,12]. Accordingly, prazosin, a highly specific α_1-antagonist in electrophysiological studies[13], completely reversed the noradrenaline- or phenylephrine-induced depression of I_A (Fig 2*d*; n = 4 and 5, respectively).

The results of the present study show that serotonergic dorsal raphe neurones possess an early transient outward current (I_A) which can be elicited by depolarizations from potentials below resting levels and is suppressed by noradrenaline or phenylephrine. As serotonergic neurones in the dorsal raphe nucleus receive a direct noradrenergic synaptic input[14], the present

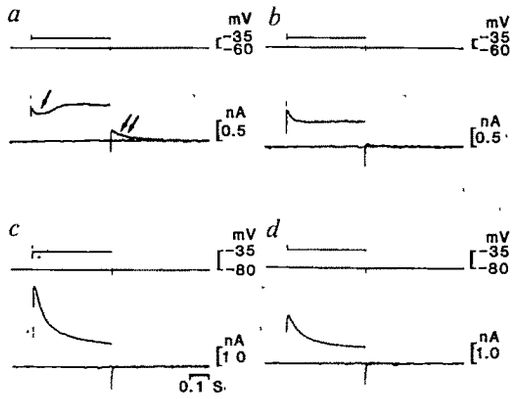

Fig. 4 Effect of the Ca^{2+}-channel blocker Cd^{2+} on the phenylephrine induced reduction of I_A. In *a*, a depolarizing step ($h = -60$ mV; holding current, +0.02 nA) to the command potential (−35 mV) induced a slow inward current (arrow) followed by a delayed outward current (note the outward tail current, double arrows); also note that at this holding potential I_A is largely inactivated. In *b*, after perfusion with Cd^{2+} (1 mM) for 20 min, the slow inward current and the subsequent outward currents are virtually abolished. In *c*, Cd^{2+} perfusion was continued but here the holding potential was changed to −80 mV to elicit I_A (note the change in current scale). I_A during Cd^{2+} was not diminished relative to its amplitude before Cd^{2+} (elicited from −80 mV, not shown). In *d*, phenylephrine (applied for 9 min) produces its usual reduction in I_A; full recovery from the effect of phenylephrine occurred within a 20-min washout period. After prolonged exposures to Cd^{2+} (for example, >1 h, not shown), it was no longer feasible to test for the response to phenylephrine because of increased membrane instability. In these experiments the artificial CSF was modified by substituting equimolar HEPES for NaH_2PO_4 to prevent the precipitation of Cd^{2+}.

results suggest that the suppression of I_A by noradrenaline represents a true neurotransmitter-induced modulation of this voltage-dependent current.

Intracellular recordings both *in vivo*[15] and *in vitro*[11] show that serotonergic neurones are tonic pacemaker cells whose spikes arise from gradual interspike depolarizations rather than discrete synaptic potentials. The interspike behaviour of unclamped serotonergic neurones is characterized by a large afterhyperpolarization (AHP), then a short period of relatively rapid depolarization, and finally a plateau region lasting several hundred milliseconds which precedes spike initiation[11]. α_1 Stimulation markedly shortens the plateau period but does not reduce the initial amplitude of the AHP[11]. Similarly, in preliminary voltage-clamp experiments, the amplitude of $I_{K(Ca)}$ was not reduced and, in fact, its duration was increased by phenylephrine and noradrenaline (Fig. 2*c* legend). This contrasts with β-adrenoceptor effects on hippocampal pyramidal neurones which are characterized by an inhibition of the Ca^{2+}-dependent AHP, resulting in increased excitability due to reduced spike frequency accommodation[16,17]. The plateau period of the pacemaker potential in serotonergic neurones occurs between −60 to −50 mV; this is precisely the range in which I_A becomes activated (Fig. 3*e*). Thus, by suppressing I_A, α_1-adrenoceptors would abbreviate this plateau period and thereby, together with a reduction in resting potassium conductance[1], accelerate pacemaker activity. It remains to be determined whether increases in neuronal excitability induced by α_1-receptors elsewhere in the CNS also involve a suppression of I_A.

I thank Dr C. F. Stevens for helpful discussion and N. Margiotta for technical assistance. This work was supported by PHS grant MH 17871 and the State of Connecticut.

Modulation of single Ca^{2+}-dependent K^+-channel activity by protein phosphorylation

Douglas A. Ewald, Alan Williams* & Irwin B. Levitan†

Graduate Department of Biochemistry, Brandeis University, Waltham, Massachusetts 02254, USA

There is considerable evidence that cyclic AMP can modulate the electrical activity of excitable cells[1–10] and that protein phosphorylation by the catalytic subunit (CS) of cAMP-dependent protein kinase is a necessary step in these modulatory effects[11–21]. In analogy to alterations in enzyme activities following phosphorylation[12], it seems possible that direct phosphorylation of ion-channel proteins may alter their gating properties, giving rise to the observed changes in electrical activity. However, the results obtained so far do not indicate whether it is ion channels themselves that are phosphorylated, or whether phosphorylation is simply an early step in some cascade of events which leads ultimately to modulation of channel activity. The development of single-channel recording techniques[22] has provided a way to investigate this question. Here we describe effects of CS on the activity of individual Ca^{2+}-dependent K^+ channels from the nervous system of the land snail *Helix* measured in isolated membrane patches and in artificial phospholipid bilayers. The results demonstrate that cAMP-dependent protein phosphorylation produces long-lasting changes in the activity of individual channels, and indicate that the relevant phosphorylation site is closely associated with the channel.

Helix ganglia contain an identified group of neurones (the F cluster) in which the outward current is predominantly Ca^{2+}-dependent[23], and DePeyer *et al.*[19] found that intracellular perfusion of CS could selectively enhance this Ca^{2+}-dependent K^+ current in such neurones. Using detached patches from these neurones in the 'inside-out' configuration[22], we have observed Ca^{2+}-dependent K^+ channels with Ca^{2+} and voltage dependences as shown in Fig. 1. The maximal single channel conductance, measured using symmetrical K^+ solutions in the detached patch configuration, is 40–60 pS. Thus, this channel is distinct from the large conductance (200–300 pS) Ca^{2+}-dependent K^+ channels which have been described in several systems[24]. Most of our experiments have been performed using 1 mM K^+ in the electrode (the outside of the membrane) and 120 mM K^+ in the solution bathing the inner membrane surface, to approximate the K^+ gradient seen by the channel in the normal cell membrane. In these conditions the apparent single-channel conductance measured at 0 mV is ~20 pS, similar to that reported by Lux *et al.*[25] for this channel in cell attached patches. Furthermore, the channel is K^+ selective, and thus is distinct from a Ca^{2+}-dependent non-selective cation channel which we have observed in *Helix* neurones (D.A.E. and I.B.L., unpublished) and which has been described previously in several cell types[26–28].

† To whom correspondence should be addressed

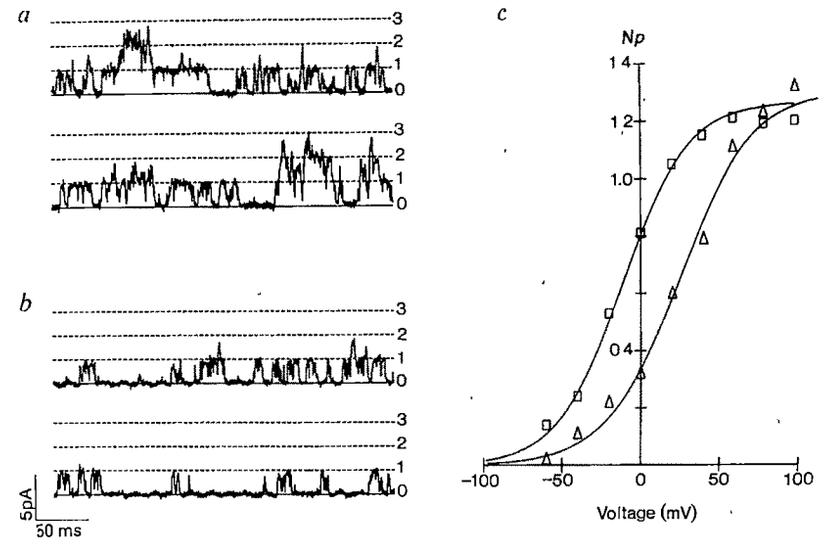

Fig. 1 A Ca^{2+}-dependent K^+ channel in an isolated patch of *Helix aspersa* neurone membrane. *a*, Continuous record of channel activity at 0 mV in a patch with its inner surface exposed to 10^{-7} M free Ca^{2+}. There are several channels in this patch (the dotted lines and the numbers to the right of the traces indicate the number of open channels). The single channel current is ~2.2 pA at the Na^+ plus K^+ reversal potential, and approaches zero at the K^+ reversal potential, indicating that the channels are K^+ selective. *b*, The same patch exposed to 10^{-8} M free Ca^{2+}. Channel activity is decreased substantially by this 10-fold decrease in free Ca^{2+}, indicating that the channels are Ca^{2+} dependent. There is no indication of any activity of other types of channels in this patch. In the experimental conditions described below, we often obtained patches such as this where the activity over a wide potential range was entirely due to this type of channel Channel activity in such patches was analysed by integrating the activity over baseline for a certain length of time and dividing by the integral of one channel being open for that length of time. Thus, channel activity is expressed in units of *Np* where *N* is the number of active channels in the patch and *p* is the probability of opening of a single channel. *c*, Analysis of channel activity in this patch as a function of membrane voltage for both 10^{-7} M (□) and 10^{-8} M (△) free Ca^{2+}. The data were fitted by eye with the approximation to a Boltzmann distribution given by $(Np)_{max}(e^{(V-V_{mid})/slope}/1+e^{(V-V_{mid})/slope})$ where *V* is membrane voltage and V_{mid} is the midpoint of the curve along the voltage axis. The fitted curves for 10^{-7} M and 10^{-8} M free Ca^{2+} had virtually the same maximum *Np* (1.25 and 1.30 respectively) and slope (*e*-fold change per 20.7 mV and 23.6 mV respectively), but the midpoints of the curves were about 30 mV apart. This shift is typical of our results in other experiments.

Methods. The *Helix* central nervous system was desheathed and decapsulated in *Helix* saline containing 80 mM NaCl, 4 mM KCl, 10 mM $CaCl_2$, 5 mM $MgCl_2$, 10 mM glucose, and 5 mM HEPES (*p*H 7.4). The exposed neurones were then bathed for 50 min at 37 °C in *Helix* saline containing 10 mg ml^{-1} trypsin. After 25 min the trypsin solution was taken up in a Pasteur pipette and gently flushed over the preparation for 2 min. Enzyme treatment was terminated with six rinses of 37 °C saline. Standard patch clamp recording techniques[22] were used to form 'inside-out' patches with seal resistances of 10 GΩ or more from neurones in the F cluster. The patch pipette solution contained 60 mM NaCl, 1 mM KCl, 40 mM $CaCl_2$, 5 mM $MgCl_2$ and 5 mM HEPES (*p*H 7.4). The inner surface of the membrane was bathed in EGTA-buffered Ca^{2+} solutions containing 5 mM EGTA, 120 mM KCl, 1 mM $MgCl_2$, 0.25 mM ATP and 5 mM HEPES (*p*H 7.4). The total concentration of $CaCl_2$ was either 1.13 mM or 3.72 mM to give free Ca^{2+} concentrations of ~10^{-8} M and 10^{-7} M, respectively. The K^+ and Na^+ concentrations in these pipette and bath solutions correspond to a K^+ reversal potential of −120 mV and a Na^+ plus K^+ reversal potential of −20 mV.

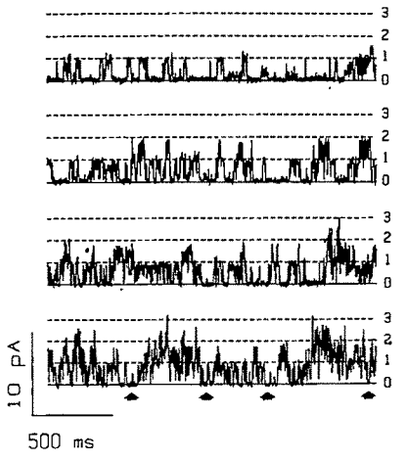

Fig. 2 Modulation of Ca^{2+}-dependent K^+ channel activity in an isolated membrane patch by catalytic subunit of cAMP-dependent protein kinase (CS) CS was purified to homogeneity by the method of Peters *et al.*[34] and stored at −20 °C. The preparation was diluted 100-fold with 10^{-8} M free Ca^{2+} bath solution immediately before use. The patch shown here was held at 0 mV in 10^{-8} M free Ca^{2+} and contained at least five Ca^{2+}-dependent K^+ channels. This continuous record of channel activity begins 50 s after exchanging the 0.2-ml chamber with 0.4 ml of 10^{-8} M free Ca^{2+} bath solution containing 0.4 μM CS. Channel activity increased abruptly during the 8 s of this record and remained at this heightened level for the remainder of the patch lifetime (5 min). Arrows below the bottom trace indicate examples of occasional time periods when all channels are closed amidst this heightened activity

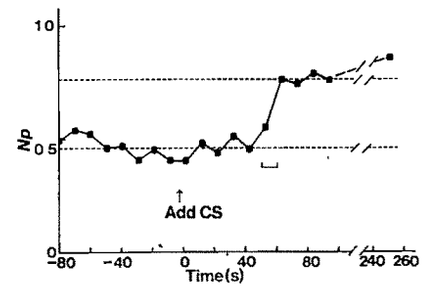

Fig. 3 Time course of the increase in Ca^{2+}-dependent K^+ channel activity produced by CS. Each point is the *Np* value for a 10.24-s interval during the 80 s before and 100 s after the addition of 0.4 μM CS (vertical arrow). The patch was held at 0 mV during this time. The traces in Fig. 2 were taken at the time indicated by the bracket, during the abrupt increase in channel activity resulting from CS addition. Dashed lines are drawn at the average *Np* levels before (*Np* = 0.45) and after (*Np* = 0.76) the abrupt increase. At 100 s, a set of voltage steps was begun which ended at 250 s, and the *Np* value at 0 mV between 250 and 260 s is also shown. In the six other experiments performed in our laboratory, the onset of the effect was similarly abrupt and in six out of seven cases the increase in channel activity lasted for at least 5 min. In four additional experiments performed in collaboration with J. DePeyer and H. Reuter, similar abrupt and long-lasting increases in the activity of this channel were seen. In all three experiments in which patches with this channel were exposed to heat-inactivated CS, no changes in channel activity were seen for at least 10 min. In one of these experiments the patch was subsequently exposed to active CS and there was an abrupt increase in channel activity within 4 min

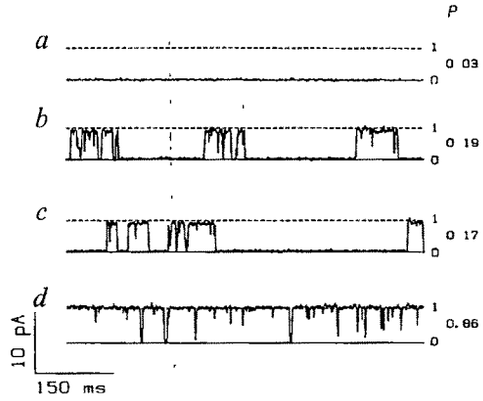

Fig. 4 Modulation of a reconstituted Ca^{2+}-dependent K^+ channel in a phospholipid bilayer formed on the tip of a patch electrode. A single channel which had been observed immediately after formation of the bilayer remained closed virtually all the time in a well containing 1.13 mM $CaCl_2$ to give a free Ca^{2+} concentration of about 10^{-8} M (*a*). When the electrode was moved to a well containing about 10^{-6} M free Ca^{2+} (4.84 mM $CaCl_2$), channel openings and closings were observed (*b*). When the bath solution contained either more or less KCl than the electrode, the single channel currents reversed at the calculated K^+ equilibrium potential (−17 mV in this experiment); furthermore addition of Na^+ to either the bath or the electrode solution had no effect on the reversal potential, indicating that the channel is K^+ selective. In some experiments the channel exhibited openings even at free Ca^{2+} concentrations as low as 1 nM, whereas in others it opened only in the presence of ≥10 μM free Ca^{2+}. Furthermore, this Ca^{2+}-dependent K^+ channel was only observed in about 30% of our membrane preparations. We cannot explain this variability between experiments However, the effects of protein phosphorylation on the activity of this channel (in this case in the presence of ~10^{-6} M free Ca^{2+}) were reliable and consistent from experiment to experiment. Treatment with 0.7 μM DTNB-inactivated CS[34] for 13 min had no effect on channel open probability (*c*). In contrast, treatment with 0.1 μM active CS led to a dramatic increase in open probability (*d*). The values to the right of each trace are channel open probabilities for each experimental condition, calculated from at least 30 s of record containing many opening and closing transitions. The voltage across the bilayer was +40 mV (corresponding to depolarization of the cell membrane) for the traces shown here.

Methods. F clusters were dissected from *Helix* central nervous system, and were rinsed sequentially with Listerine, then with 10 mM EGTA (*p*H 7.4), and finally with 20 mM HEPES (*p*H 7 4). They were then homogenized in the latter buffer (clusters from five *Helix* per ml of homogenizing buffer) using five strokes of a glass-glass homogenizer The homogenate was centrifuged at 10,000*g* for 15 min and the pellet was discarded The supernatant was centrifuged at 100,000*g* for 60 min; the resulting supernatant was discarded and the pellet was taken as the source of membranes. The pellet was resuspended in 200 μl of 200 mM KCl, 20 mM HEPES (*p*H 7.4) by homogenization. To this was added 200 μl of a mixture of brain phosphatidylethanolamine/phosphatidylserine (PE/PS, 3/1; Avanti) which had been suspended in 20 mM HEPES and sonicated until the suspension was clear. $CaCl_2$ was added to a final concentration of 0.1 mM, and the membrane/phospholipid mixture was frozen and thawed three times The reconstituted preparation contained, in a total volume of 400 μl, 300–500 μg membrane protein ml^{-1}, 4 mg phospholipid ml^{-1}, 20 mM HEPES, 100 mM KCl and 0 1 mM Ca^{2+} This preparation (100 μl) was placed in a well of a sterile microtitre plate (Falcon). A fresh plate was used for each experiment and all solutions were filtered through 0.45 μm filters to avoid spurious channels arising from bacterial contamination. The preparation was left for at least 5 min at room temperature to allow a phospholipid monolayer to form at the air/liquid interface. A fire polished patch electrode containing 50 mM KCl, 20 mM HEPES (*p*H 7.4) was pulled through the monolayer twice to form a bilayer on the electrode tip[32,33]. The seal resistance for this experiment was 17 GΩ, and the bandwidth was 1 kHz. Current across the bilayer was monitored, and when single-channel currents were detected the electrode was moved to an adjacent chamber containing 100 mM KCl, 20 mM HEPES (*p*H 7.4), 1 mM $MgCl_2$, 0.25 mM ATP, 5 mM EGTA, and $CaCl_2$ and enzymes as described above

Figure 1*c* shows the voltage dependence of channel opening at two different Ca^{2+} concentrations. Because we never obtain patches which contain only one Ca^{2+}-dependent K^+ channel, channel activity is expressed in units of *Np*, where *N* is the number of active channels in the patch and *p* is the open probability for an individual channel. Note that increasing the Ca^{2+} concentration shifts the *Np*-voltage curve to the left, with little change in slope or in the maximum *Np* value. The shift in the mid-point of the curve is ~30 mV for a 10-fold change in Ca^{2+} concentration.

We have investigated the possibility that the activity of this channel can be regulated by cAMP-dependent protein phosphorylation, by applying CS together with Mg^{2+} and ATP directly to the inner membrane surface of inside-out patches. The results of one such experiment are illustrated in Fig. 2. At the beginning of the record (top trace) the channel activity is that normally observed in the presence of 10^{-8} M Ca^{2+} at this voltage (0 mV, compare with Fig. 1*b*). During the 8-s period shown, channel activity increases dramatically, so that by the end of the record (bottom trace) several channels are open a large portion of the time.

Figure 3 shows the time course of the onset of this response. It can be seen that the *Np* value was stable before and for almost 1 min after addition of CS (vertical arrow), and then abruptly increased to reach a new stable level. Such abrupt increases in activity were observed in all experiments in which active CS was added ($n = 7$), with a latency ranging from 12 s to 4 min. In all but one experiment the activity remained elevated for many minutes, often for as long as we could hold the patches, although on occasion there did seem to be some reversal with time. In contrast to these results with active CS, we have never seen such changes in channel activity either spontaneously, or following addition of heat-inactivated CS.

A consistent finding in all our experiments is that CS causes an increase in *Np* at all voltages between −60 and +100 mV. Although the reasons are unclear, it seems likely that CS is having more than one effect. The results are consistent with the possibility that phosphorylation leads to an increase in the affinity of Ca^{2+}-dependent K^+ channels for Ca^{2+}, which shifts the *Np*-voltage curve to the left at negative voltages. The maximum *Np* at positive voltages is also increased, which is consistent with an increase in the number of functional channels in the patch, or with an increase in the maximum open probability for a given channel.

These and other isolated patch experiments[29,30] have provided direct evidence that the activity of individual channels can be modulated by cAMP-dependent protein phosphorylation, and demonstrate that the phosphorylation target must be something which remains associated with the patch of membrane when it is detached from the cell. This target may be the channel itself, or it may be some other membrane-associated element (for example, a cytoskeletal component) which comes away with the patch. To study this further, we have examined channel activity in a reconstituted system using homogenized F cluster neurones dissected from *Helix* ganglia and a crude membrane vesicle fraction prepared by differential centrifugation. When these vesicles are allowed to fuse with artificial phospholipid bilayers in conditions which permit the measurement of single channel currents across the bilayer[31], we find at least five separate K^+ channels which can be distinguished on the basis of their kinetics and single channel conductances (I.B.L. and A.W., in preparation). At least one of these K^+ channels is Ca^{2+}-dependent. These experiments have been performed in several different configurations, including large planar bilayers (80–200 μm diameter) formed across an opening between two chambers[31], and in bilayers formed on the tip of a patch electrode ('tip-dipping')[32,33]. Figure 4 illustrates an experiment in which a single Ca^{2+}-dependent K^+ channel was present in the artificial membrane on the tip of a patch pipette. This channel has a single-channel conductance of 70–100 pS, somewhat larger than that of the Ca^{2+}-dependent K^+ channel observed in membrane patches. It also seems to be less sensitive to Ca^{2+}, although the

Ca^{2+} sensitivity of the bilayer channel varies markedly between experiments. It remains to be determined whether the channels in the patch and the bilayer are distinct, or whether the apparent differences in some of their properties result simply from differences in their membrane environment.

The bilayer channel is closed virtually all of the time in 10^{-8} M Ca^{2+} at +40 mV (Fig. 4*a*), but is open for a significant time when the Ca^{2+} concentration is raised to 10^{-6} M (Fig. 4*b*). This degree of Ca^{2+} sensitivity is in the middle of the wide range that we observed. There is no effect on channel activity after prolonged treatment (in this case 13 min) with dithionitrobenzene (DTNB)-inactivated or heat-inactivated CS (Fig. 4*c*). However, the opening and closing kinetics of the channel change dramatically within 20 s of the addition of active CS, with a large increase in open probability (Fig. 4*d*). The latency for the onset of the response ranged from too fast to measure (that is, <5 s) to as long as 7 min. The *p* values to the right of each trace in Fig. 4 demonstrate the magnitude of the probability change at +40 mV produced by phosphorylation with active CS; such changes were observed in all the experiments ($n = 11$) carried out with either the large planar bilayers or the 'tip-dip' technique. Investigation of the change in probability elicited at various voltages by CS treatment produced results (not shown) entirely consistent with a shift in channel affinity for Ca^{2+}.

Previous studies from our own and other laboratories have provided evidence that protein phosphorylation can regulate the membrane properties of excitable cells. The present results extend these findings by demonstrating directly that the activity of individual Ca^{2+}-dependent K^+ channels can be modulated by cAMP-dependent protein phosphorylation. In addition, the results put the phosphorylation site considerably closer to the channel; indeed, from the reconstitution experiments, in which individual channels are effectively at infinite dilution in the bilayer, we conclude that the phosphorylation target is either the K^+ channel itself or something intimately associated with the channel. Finally, clues have been provided about those aspects of channel function which are modulated by phosphorylation, and it will be of great interest to extend these approaches to investigate the detailed molecular mechanisms of ion-channel regulation.

We thank Dr Christopher Miller for advice on bilayer strategy and tactics, and Drs Miller, Gary Yellen and John Lisman for their critical comments on the manuscript. Several early phosphorylation experiments in the isolated patch were done with Drs Harald Reuter and Jacques DePeyer at the University of Bern; we thank them for their collaboration and for teaching us how to patch clamp. This work was supported by NIH grant NS17910 to I.B.L.

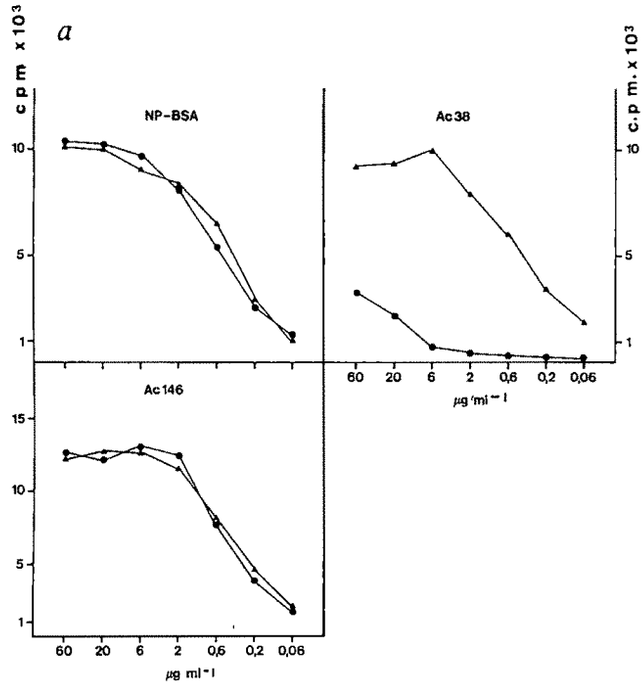
Drastic change in idiotypic but not antigen-binding specificity of an antibody by a single amino-acid substitution

Andreas Radbruch, Siegfried Zaiss, Claudia Kappen, Marianne Brüggemann, Konrad Beyreuther & Klaus Rajewsky

Institute for Genetics, University of Cologne, Weyertal 121, D-5000 Koln 41, FRG



In proliferating B lymphocytes, somatic mutation of rearranged antibody variable (V)-region genes occurs at high frequency and may have a key role in the selection of these cells[1–3]. It is of interest in this context to learn in which way single mutations can affect antigen binding and/or idiotypic specificity of an antibody. Previous investigations have analysed spontaneous mutants of myeloma and hybridoma cells in which the mutation affected the antigen-binding specificity of the antibody[4–8]. Here we describe an antibody mutant that has fully retained antigen-binding specificity but has lost or drastically changed all V-region antigenic determinants (idiotopes) of the wild type as defined by monoclonal anti-idiotope antibodies. The mutant phenotype is generated by a glycine to arginine exchange in the middle of the diversity (D) element, at position 103 of the heavy chain.

The mutant was derived from the monoclonal antibody B1-8.δ1, which binds the hapten 4-hydroxy-3-nitro-5-iodophenylacetyl (NIP) with high affinity[9,10]. From a series of monoclonal anti-idiotope antibodies raised against antibody B1-8 (refs 11, 12), two were used for mutant selection. Antibody Ac38 defines an idiotope (idiotope Ac38) outside the hapten-binding cleft. In contrast, idiotope Ac146, recognized by antibody Ac146, is presumably located close to the hapten-binding site because hapten and antibody Ac146 compete for binding to the B1-8 V region. Spontaneously arising idiotope loss mutants of B1-8.δ1 were isolated by fluorescence-activated cell sorting. It has been shown previously that an $Ac146^-Ac38^+$ mutant has lost hapten-binding specificity together with the binding site-related idiotope Ac146[4]. The present experiments describe a mutant selected for the expression of the latter idiotope and against expression of idiotope Ac38.

Table 1 Affinity and fine specificity of hapten binding to wild-type and mutant antibody

	IC_{50} NIP-cap (M)	IC_{50} NP-cap (M)	Fine specificity
B1-8.δ1	1×10^{-7}	2×10^{-5}	NNP = NIP > NCLP = NP
B1-8 δ1V3	1.1×10^{-7}	1.8×10^{-5}	NNP = NIP > NCLP = NP

The IC_{50} value is the molar hapten concentration resulting in 50% inhibition of binding of antibody (60 μg ml^{-1}) to N^{125}IP-cap (4×10^{-8} M), determined by Farr assay as described in ref. 9. For unknown reasons, IC_{50} values for NP-cap differed reproducibly by an order of magnitude from those published previously[10]. The order of haptens according to affinity was: NNP, (4-hydroxy-3,5-dinitrophenyl)acetyl; NIP, (4-hydroxy-5-iodo-3-nitrophenyl)acetyl; NCLP, (4-hydroxy-5-chloro-3-nitrophenyl)acetyl; NP, (4-hydroxy-3-nitrophenyl)acetyl

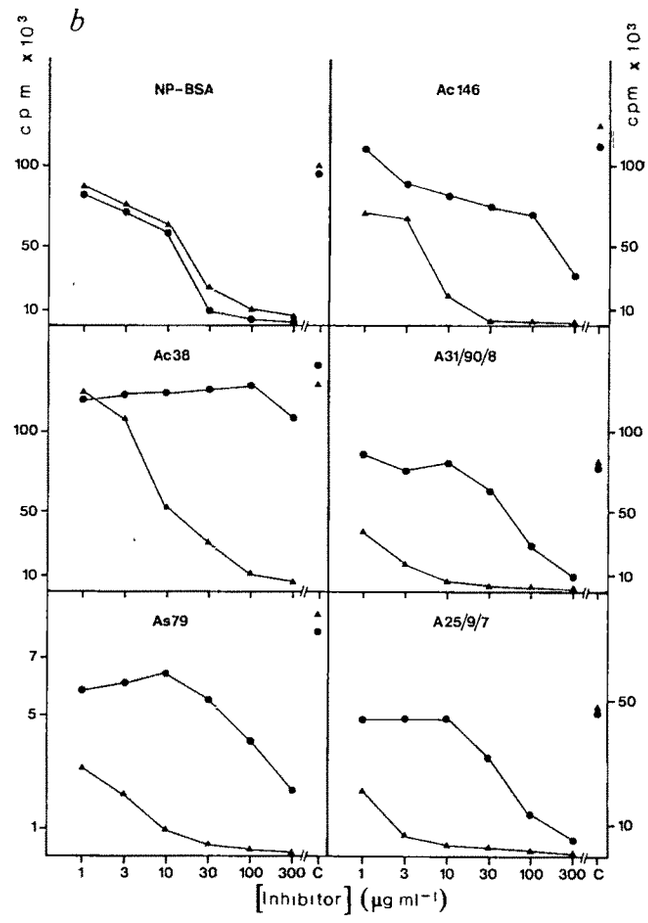


Fig. 1 Serological analysis of B1-8.δ1 (▲) and B1-8 δ1V3 (●) *a*, Direct binding in a solid-phase radioimmunoassay[26]. Plastic plates were coated with NIP-BSA or anti-idiotope antibody at a concentration of 50 μg ml^{-1} After saturating the plastic surface with BSA, B1-8 δ1 or B1-8.δ1V3 antibody was added to the coated wells at the concentrations indicated on the abscissa, and bound antibody detected with ^{125}I-labelled monoclonal anti-mouse λ1-chain antibody Ls136 (0.5 μg ml^{-1}; refs 11, 27). Results are shown for NIP-BSA and the anti-idiotopes Ac146 and Ac38. The anti-idiotope antibodies Ac106, As79, A25 9.7 and A31 90.8 behaved like antibody Ac38 in that they failed to bind the mutant B1-8.δ1V3 (data not shown). *b*, Binding inhibition The binding of iodinated antibody B1-8.δ1 to NIP-BSA or anti-idiotope-coated plates was inhibited by graded concentrations (abscissa) of unlabelled antibody B1-8 δ1 (▲) or B1-8.δ1V3 (●). Control binding without inhibitor is indicated (C)

B1-8.δ1 cells were incubated with fluoresceinated antibody Ac146 (50 μg ml^{-1}) in the presence of a 100-fold excess of unlabelled antibody Ac38. In these conditions, only cells that have retained the expression of idiotope Ac146 but lost that of idiotope Ac38 are stained. Stained cells were then enriched in eight successive rounds of sorting, expanding the separated cells after each sort. The mutant cells were finally isolated by cloning and identified by a radioimmunoassay of culture supernatant. Fifteen clones produced antibodies of mutant phenotype, that is, antibodies binding to antibody Ac146 but not to antibody Ac38. The frequency of the variant cells in the original B1-8.δ1 population is presumably $>2\times10^{-8}$, as about 5×10^{7} cells were used in the initial sorts. On the other hand, Ac146^{+}Ac38^{-} cells were not detected in the original population by fluorescence microscopy, staining the cells simultaneously with the two anti-idiotope antibodies coupled to different fluorochromes[4] and repeatedly screening 1×10^{5} cells. These results are consistent with previous data[4] and indicate that the frequency of a given idiotype variant in B1-8.δ1 cells is at least one order of magnitude lower than the frequency of variants of the myeloma S107 which have lost the property of antigen binding.

Because of the rare occurrence of the variants and the fact that three of the variant cell clones behaved identically when tested with a variety of other anti-idiotopes, it seemed unlikely that we had isolated a series of independent mutants. Therefore, we chose only one clone, B1-8.δ1V3, for a detailed characterization. The antibody produced by this clone (antibody B1-8.δ1V3) was assayed for binding to a NIP-conjugate of bovine serum albumin (NIP_{14}-BSA) and the anti-idiotope antibodies

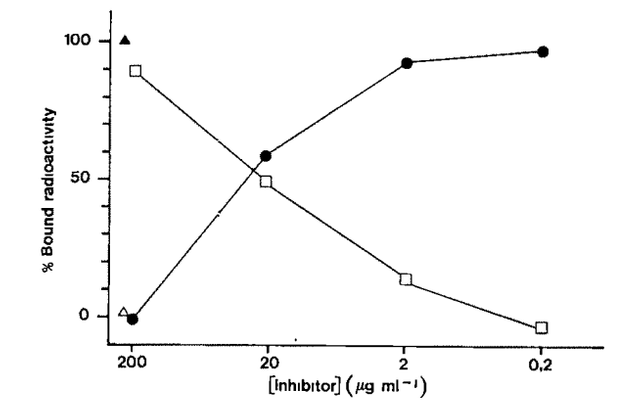

Fig. 2 Binding of λ1 light chain to variant and wild-type heavy chain. The myeloma protein HOPC1 (IgG2a, λ1) and IgD from B1-8.δ1 and B1-8.δV3 were mildly reduced with 10 mM dithioerythrol (150 min, room temperature, in the dark) and light and heavy chains separated on a Sephadex G-150 column (Pharmacia) in 1 M acetic acid with 10 mM dithioerythrol. The various fractions were dialysed first against 10 mM sodium acetate *p*H 5.5 and then against phosphate-buffered saline (PBS). When tested on a 7 5% SDS-polyacrylamide electrophoresis gel, the separated chains were >95% pure HOPC1 λ1 chains were iodinated[27], re-associated at 20 μg ml^{-1} in PBS with 1% BSA at 4 °C overnight to either B1-8.δ1 (▲) or B1-8.δ1V3 (△) heavy chains (20 μg ml^{-1}) and tested for binding to an Ac38 (30 μg ml^{-1}) anti-idiotope-coated plastic plate. The λ1 chains can bind to the anti-idiotope only when associated with a B1-8 δ1 chain. Bound λ1 chains were counted in a γ-counter. The re-association of λ1 to B1-8.δ1 or B1-8.δ1V3 heavy chains was inhibited by increasing amounts (abscissa) of B1-8.δ1V3 (●) or B1-8 δ1 (□) heavy chains, respectively The two curves cross each other at roughly 50% binding, indicating a similar affinity of the two heavy chains for the λ1 light chain

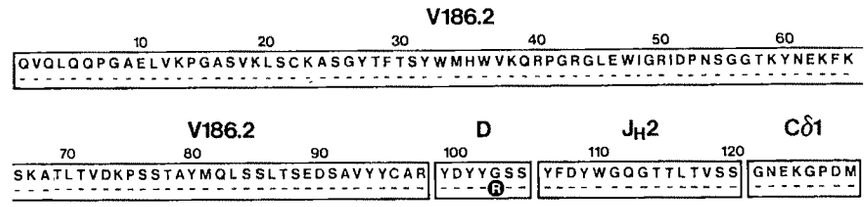

Fig. 3 Amino-acid sequence of the B1-8.δ1V3 heavy-chain variable region. The B1-8 δ1V3 antibody was cleaved by cyanogen bromide and the three fragments of the heavy-chain variable region isolated as described for B1-8 δ1 and B1-8.δ1V3 (refs 5, 28). Because H1 (residues 1–34) and H3 (residues 82–128) are blocked by the presence of N-terminal pyroglutamic acid[8], only H2 (residues 35–81) was sequenced directly by automated Edman degradation in a spinning-cup sequencer. Fragments H1, H2 and H3 were cleaved with trypsin or/and thermolysine and the fragments isolated by reverse-phase HPLC. The peptides were identified by amino-acid analysis and compared with the B1-8.δ1 sequence (upper line, single-letter code). The peptides covering residues 20–34 and 99–128 were sequenced in a gas-phase sequencer[29]. The amino-acid compositions of the peptides covering residues 1–21 and 82–98 isolated from B1-8.δ1 and B1-8.δ1V3 were indistinguishable, suggesting that for these parts both heavy chains are identical. The sequence of B1-8.δ1V3 (lower, dashed line) shows at position 103 an arginine residue instead of the glycine found for B1-8.δ1. The region of the variable regions encoded by the *D* gene (D), J_H2 gene (J_H2) and the J_H2 border to the first constant domain ($C_\delta1$) are indicated by vertical lines.

Ac146, A25.9.7, Ac38, A31.90.8, A6.24, As79 and Ac106. Efficient binding was observed only in the case of NIP-BSA and antibody Ac146 (Fig. 1*a*). The Ac146 determinant, however, is also affected by the mutation, as the B1-8.δ1V3 antibody was about 100-fold less efficient than the wild type in inhibiting the binding of radiolabelled antibody B1-8.δ1 to antibody Ac146 (Fig. 1*b*). In the case of the anti-idiotopes Ac38, A25.9.7, As79 and A31.90.8, binding inhibition by the mutant was even less efficient.

Despite its drastic idiotypic alteration, the mutant antibody inhibited the binding of the B1-8.δ1 wild type to NIP-BSA with the same efficiency as the wild-type antibody itself (Fig. 1*b*), and the affinities of both antibodies to NIP and some related haptens were identical within the limits of the analysis (Table 1).

The mutation in B1-8.δ1V3 was localized to the heavy chain. In chain re-association experiments, mutant and wild-type heavy chains, when re-associated to λ1 chains of the myeloma HOPC1, gave rise to mutant and wild-type immunoglobulin, respectively. The mutation does not interfere with the capacity of the heavy chain to bind light chain, as the two heavy chains competed with equal efficiency for re-association to λ1 (Fig. 2). Isoelectric focusing of Fv fragments revealed a small but distinct difference between the C-terminal heavy-chain variable-region fragments (relative molecular mass 19,000) of mutant and wild-type immunoglobulin (data not shown).

The amino-acid sequence of the V_H, D and joining (J) segments of the B1-8.δ1V3 heavy chain, determined by the strategy developed previously for the sequencing of B1-8.δ1V1 (ref. 5), revealed a single amino-acid difference between variant and wild type; at position 103 a glycine residue is changed to an arginine residue (Fig. 3).

In the previously isolated mutant, B1-8.δ1V1 (ref. 4), recombination (conversion) between the expressed and a non-rearranged V_H gene had generated the mutant phenotype[5,6]. Although we cannot exclude such an event in the case of B1-8.δ1V3, it seems more likely that in this antibody a point mutation has occurred, changing the glycine-encoding triplet GGT at position 103 (ref. 13) into CGT, encoding arginine. Point mutation is also the simplest explanation for the generation of mutants of the S107 myeloma line with changed antigen-binding specificity[8,14].

The observations that single amino-acid substitutions can profoundly affect idiotypic and/or antigen-binding specificity and that the D element has a key role in determining idiotypic specificity are not new[3,15–20]. The main point of the present analysis is the demonstration that a single amino-acid exchange in D can essentially eliminate the reactivity of an antibody with the majority of the anti-idiotopes raised against it, while leaving hapten-binding specificity intact. The conservation of NIP-binding specificity in the mutant, its reactivity with the NIP group on a macromolecular carrier (BSA), and the chain re-association data argue that the mutation has left the overall structure of the antibody and the hapten-binding cleft intact and selectively changed a surface structure (arginine 103 is a surface residue according to ref. 21) of key importance for idiotypic recognition. This structure may be directly involved in the interaction of the various anti-idiotope antibodies with the B1-8 V region. Like other protein interactions, idiotypic interactions seem in general to involve extended areas on the protein surface[3,19]. In the present system it has been shown that, in addition to D, residues in V_H and the V region of the light chain all contribute to the reactivity of antibody B1-8 with various anti-idiotopes[3,4,22]. It is therefore not surprising that, as far as analysed, the anti-idiotope antibodies compete with each other in binding to antibody B1-8 (ref. 11). Nevertheless, the points of contact differ for the various antibodies, as none of the target idiotopes is necessarily co-expressed with any other (refs 12, 23, 24 and our unpublished observations). Only some of the idiotopes are intimately associated with the hapten-binding site[11,12].

In biological terms, the B1-8.δV3 mutant demonstrates that a single amino-acid exchange can make an antibody essentially invisible for a variety of anti-idiotypic antibodies. Thus, somatic mutation can easily mediate escape from idiotypic control[25].

The phagocytic function of neutrophils is a crucial element in host defence against invading microorganisms. Two main specific receptor-mediated mechanisms operate in the phagocyte plasma membrane, one recognizing the C3b/bi fragment of complement and the other the Fc domain of immunoglobulin G (ref. 1). There is evidence that phagocytosis mediated by these receptors differs in the number and nature of the intracellular signals generated[2–5]. However, the mechanism by which receptor binding is transduced into a signal that generates the formation of the phagocyte pseudopod is not known, although extensive biochemical evidence has allowed the postulate that calcium ion gradients in the peripheral cytoplasm, by interacting with calcium-sensitive contractile proteins, initiate the process of engulfment[6]. Using the high-affinity fluorescent calcium indicator quin2 both to measure and to buffer intracellular calcium ($[Ca^{2+}]_i$), we show here that in human neutrophils two mechanisms of phagocytosis coexist: a $[Ca^{2+}]_i$-dependent and modulated phagocytosis, triggered by activation of the Fc receptor, and a $[Ca^{2+}]_i$-independent mechanism triggered by the activation of the C3b/bi receptors.

To monitor changes in $[Ca^{2+}]_i$ during phagocytosis, human neutrophils loaded with quin2 were exposd to yeast (*Saccharomyces cerevisiae*) particles coated with IgG, C3bi or heat-inactivated serum. Figure 1 shows how $[Ca^{2+}]_i$ changes during the phagocytosis of different particles and also the kinetics of phagocytosis, expressed as a percentage of phagocytosing cells, in the same batch of quin2-loaded neutrophils. In contrast to the observations of Campbell *et al.*[7] with latex particles, we found that with both IgG- and C3bi-coated yeasts, $[Ca^{2+}]_i$ rises after a lag time of 2–3 min, reaching a plateau at about 4–6 min and remaining elevated for >10 min. Both the lag time and the maximum rise in $[Ca^{2+}]_i$ was dependent on the yeast to cell ratio and the intracellular quin2 concentration (see below). No $[Ca^{2+}]_i$ increase was observed with unopsonized yeast that was not ingested (Fig. 1*c*). In several experiments, with both IgG- and C3bi-coated yeast, phagocytosis began slightly before the rise in $[Ca^{2+}]_i$ became detectable. With cells loaded with 10 μM quin2 (same conditions as for Fig. 1), the rise in $[Ca^{2+}]_i$ was detected on average within 1.8 ± 0.4 ($n = 9$) for C3bi-coated yeast and 2.8 ± 0.5 min ($n = 12$) for IgG-coated yeast whereas phagocytosis was already detectable at 1 min for both IgG-coated yeast ($7 \pm 3\%$ ingesting cells, $n = 5$) and C3bi-coated yeast ($27 \pm 8\%$, $n = 5$).

This kinetic discrepancy between the increase in $[Ca^{2+}]_i$ and phagocytosis may be explained in two ways. First, the kinetics of the $[Ca^{2+}]_i$ increase and that of yeast ingestion are similar, but because the rise in $[Ca^{2+}]_i$ occurs initially in a small proportion of cells, possibly in the cortical cytoplasm, the average value of $[Ca^{2+}]_i$ for the whole cell population, which is what quin2 actually measures, would be affected only to a small extent; only when a large number of cells becomes engaged in phagocytosis, and perhaps the increase in $[Ca^{2+}]_i$ spreads throughout the cytoplasm, is a significant average increase in $[Ca^{2+}]_i$ revealed by quin2. Furthermore, for a process like phagocytosis, which occurs as discrete events in a proportion of the whole cell population, the quin2 technique, by definition, underestimates the real rise in $[Ca^{2+}]_i$ in the cells actually engaged in particle ingestion. Figure 1 (inset) shows that soluble

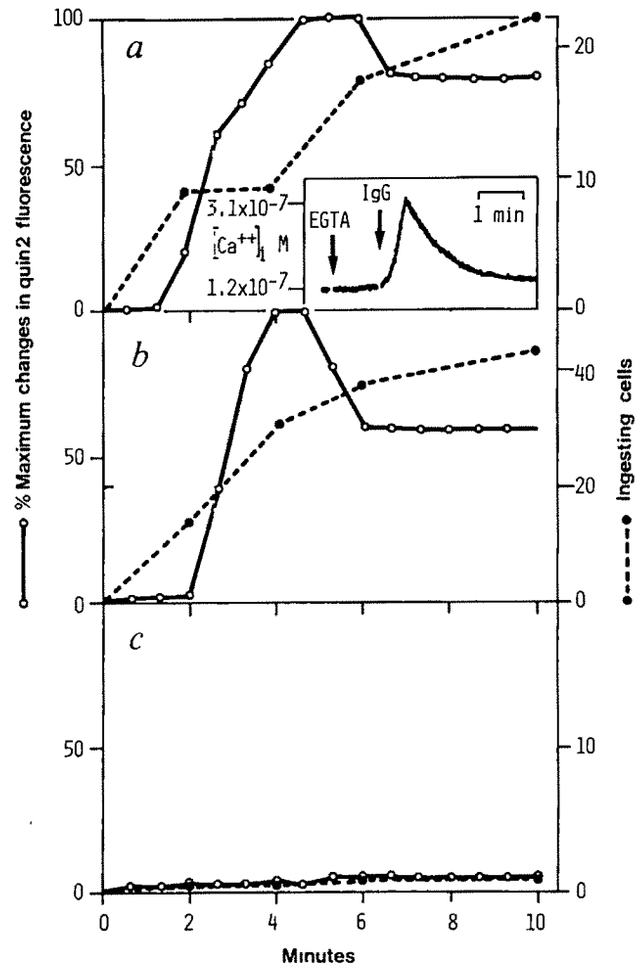

Fig. 1 Changes in $[Ca^{2+}]_i$ and phagocytosis of yeast particles by neutrophils. *a*, An experiment using yeast particles coated with rabbit anti-yeast IgG. The inset shows the effect of heat-aggregated (63 °C, 30 min) human IgG (500 μg ml^{-1}) on $[Ca^{2+}]_i$ in cells incubated in Ca^{2+}-free medium + 1 mM EGTA. *b*, *c*, Experiments using C3bi-coated yeast particles (*b*) and unopsonized yeast particles (*c*). **Methods.** Purified neutrophils were loaded with the fluorescent probe quin2/AM as described previously[11]. Loaded cells were incubated in a spectrofluorometer (Perkin-Elmer LS3) at 37 °C with a stirring system, and $[Ca^{2+}]_i$ as well as phagocytosis in suspension were measured. Because the phagocytic assay uses fluorescein isothiocyanate (FITC)-labelled yeast particles[2], both experiments were performed in parallel with different aliquots from the same batch of cells. Intracellular quin2 was 0.1 nmol per 10^6 cells. Cells (5×10^6) were incubated with yeast particles (2.5×10^7) in a total volume of 2.9 ml buffer containing 138 mM NaCl, 6 mM KCl, 1 mM $MgSO_4$, 1.1 mM $CaCl_2$, 5 mM $NaHCO_3$, 100 μM EGTA, 5.5 mM glucose, 20 mM HEPES, *p*H 7.4. The IgG-coated particles were opsonized by incubating yeast with purified anti-yeast IgG (20 μg ml^{-1}) in the presence of 20% heat-inactivated (56 °C, 30 min) human serum; C3bi-coated particles were opsonized by incubating the yeast with 20% fresh normal serum and unopsonized particles were incubated with 20% heat-inactivated serum. All particles were incubated at 37 °C, 30 min and washed before use. No IgG was detected on the surface of the yeast incubated with serum[2]. Phagocytosis of FITC-labelled yeast particles was monitored by the fluorescent quenching method[2], where the extracellular particles are quenched by adding trypan blue. Phagocytosis is expressed as the percentage of phagocytosing cells. The uptake of C3bi-coated particles was furthermore blocked by $F(ab')_2$ anti-C3c (J. H. and O.S., unpublished observation). All the above experiments were performed on the same batch of quin2-loaded neutrophils. For total change in quin2 fluorescence, see Fig. 2 showing similar results.

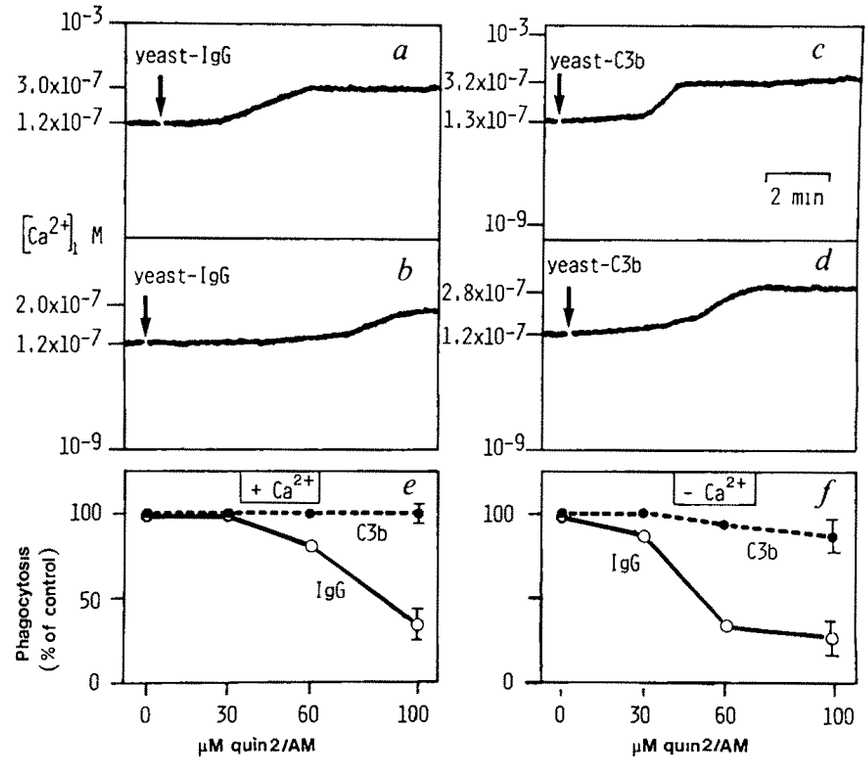

Fig. 2 Changes in $[Ca^{2+}]_i$ and phagocytosis of C3bi- and IgG-coated yeast particles by neutrophils loaded with different concentrations of quin2. *a–d*, Neutrophils were loaded with 10 or 30 μM quin2/AM and $[Ca^{2+}]_i$ was monitored. Intracellular quin2 concentration per 10^6 cells were 0.11 and 0.34 nmol, respectively *a*, *c*, Cells loaded with 10 μM; *b*, *d*, cells loaded with 30 μM quin2/AM The number of neutrophils and yeast particles were as for Fig. 1 legend. *e*, *f*, The effect of increasing cytosolic calcium buffering capacity by increasing intracellular quin2, on IgG- and C3bi-mediated phagocytosis. *e*, Cells incubated with various concentrations of quin2/AM in the presence of 1 mM Ca^{2+} for 60 min at 37 °C. The phagocytosis assay was performed with washed cells in the same medium containing 1 mM Ca^{2+} *f*, Phagocytosis by cells incubated with various concentrations of quin2/AM in the absence of extracellular Ca^{2+} + 1 mM EGTA ($[Ca^{2+}]_0 = 10^{-9}$ M). This procedure depletes the cells of intracellular calcium[12]. The cells were then incubated in Ca^{2+}-free medium at 37 °C for 5 min before yeast particles and Ca^{2+} (final concentration 200 μM) were added. This concentration of calcium is necessary to establish good binding of the yeast particles to the neutrophils Phagocytosis was monitored as described in Fig. 1, and expressed as the % of phagocytosing cells after 10 min. 100% = % of phagocytosing cells in the absence of quin2. The values for IgG- and C3b-coated yeast phagocytosis in the absence of quin2 were 30% and 64%, respectively.

aggregated IgG, presumably by interacting with several receptors on most cells, initiates and mediates a rapid increase in $[Ca^{2+}]_i$ from intracellular stores, as also shown by others[8,9]. (For further discussion of the problem of cell heterogeneity, see refs 10 and 11.) A second possibility is that phagocytosis itself does not require an increase in $[Ca^{2+}]_i$ which, if correct, would indicate that the increase in $[Ca^{2+}]_i$ observed with IgG- and C3bi-coated yeast is an event that is secondary to phagocytosis and/or receptor triggering, and not directly related to the process of particle ingestion.

To determine the role of the increase in $[Ca^{2+}]_i$ in phagocytosis, we used the fact that quin2 not only measures $[Ca^{2+}]_i$, but can also act as a high-affinity calcium buffer inside the cells. Thus, increasing the intracellular quin2 concentration, $[quin2]_i$, should decrease the amplitude and/or delay the increase in $[Ca^{2+}]_i$. The presence of increasing concentrations of quin2 inside the cells should, furthermore, counteract the formation of large $[Ca^{2+}]_i$ gradients within the cell (see also ref. 12). Thus, it can be predicted that if phagocytosis casually depends on a local, or average, rise in $[Ca^{2+}]_i$, it should be inhibited and/or delayed by increasing $[quin2]_i$. Figure 2*a–d* shows that increasing $[quin2]_i$ decreases the amplitude and delays the appearance of the yeast-induced elevation of $[Ca^{2+}]_i$. However, although the effect of quin2 loading on $[Ca^{2+}]_i$ is similar for both IgG- and C3bi-coated particles, its effect on phagocytosis is strikingly different. Figure 2*e*, *f* shows that phagocytosis of IgG-coated yeast is decreased markedly as a function of quin2 loading whereas ingestion of C3bi-coated particles is unaffected by increasing the intracellular calcium-buffering capacity; the percentage of ingesting cells (Fig. 2) and the number of ingested IgG-coated yeast molecules per cell are reduced to the same extent. The inhibitory effect of $[quin2]_i$ on IgG-mediated phagocytosis was more pronounced in cells that had been loaded with quin2 in the absence of extracellular Ca^{2+} ($[Ca^{2+}]_0$) + EGTA ($[Ca^{2+}]_0 = 10^{-9}$ M), a condition which decreases basal $[Ca^{2+}]_i$ and depletes intracellular Ca^{2+} stores[12]. In contrast, C3bi-coated yeast particles were ingested to the same extent and with the same rate independently of the loading conditions. In cells loaded with quin2 in Ca^{2+}-free buffer + EGTA, resting $[Ca^{2+}]_i$ was reduced to below 10 nM; the addition of Ca^{2+} (200 μM) produced a slow (5 min) increase in $[Ca^{2+}]_i$ towards basal levels, the rate of the rise being unaffected by the simultaneous addition of Ca^{2+} and opsonized yeast.

Taken together, these data suggest that Fc receptor-triggered phagocytosis depends on $[Ca^{2+}]_i$ transients, possibly localized to some specific regions of the cytoplasm, whereas C3bi receptor-mediated phagocytosis occurs at the same speed and to the same extent independently of $[Ca^{2+}]_i$ A major problem in considering C3bi-mediated phagocytosis as a completely $[Ca^{2+}]_i$-independent process, however, is the finding that at least 100 μM Ca^{2+} must be present in the medium before yeast particle ingestion is observed. This probably does not result from an effect on $[Ca^{2+}]_i$, but reflects a role for $[Ca^{2+}]_0$ in the interaction between the surface of the cell and the yeast. It remains possible, however, that $[Ca^{2+}]_0$ is required to induce local changes in $[Ca^{2+}]_i$ or that receptor triggering sensitizes the phagocyte machinery to resting levels of $[Ca^{2+}]_i$. To exclude these two possibilities, it would be necessary to reduce $[Ca^{2+}]_i$ to 10 nM and maintain it at this low concentration throughout phagocytosis. At such a low Ca^{2+} concentration, all known Ca^{2+}-dependent processes are almost completely inhibited[13–16]. To study phagocytosis in the absence of extracellular calcium, C3b-opsonized endotoxin-coated oil particles were used which are efficiently ingested even at $[Ca^{2+}]_0 = 1$ nM[17]. Figure 3 (right panel) shows initial ingestion of C3b-opsonized oil particles by neutrophils loaded either in Ca^{2+}-containing medium ($[Ca^{2+}]_i = 120$ nM) or in Ca^{2+}-free medium + EGTA ($[Ca^{2+}]_i = 10$ nM), and tested in Ca^{2+}-free medium + EGTA. Ingestion of C3b-opsonized oil droplets, at $[Ca^{2+}]_0 = 1$ nM, was identical whether the $[Ca^{2+}]_i$ was 10 nM, where no Ca^{2+} would be released by ionophore, or $[Ca^{2+}]_i$ = 120 nM and in the presence of ionophore-releasable pools. The oil particles are, unfortunately, strongly fluorescent at the quin2 wavelength, which prevents us from monitoring $[Ca^{2+}]_i$ during oil droplet phagocytosis.

The experiments shown in Fig. 3 support the $[Ca^{2+}]_i$ dependency and independency of Fc- and C3b/bi-mediated

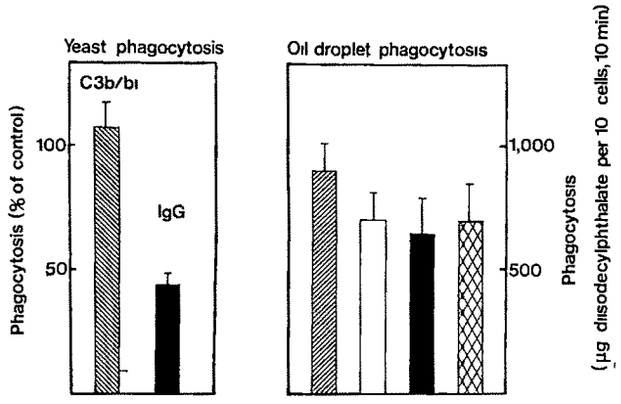

Fig. 3 *a*, Effect of the calcium ionophore ionomycin (1 μM) on phagocytosis of C3bi- or IgG-coated yeast in Ca^{2+}-containing medium. The ionophore was added 1 min before the yeast particles. Incubation time was 10 min. Phagocytosis was monitored as described in Fig. 1 legend and expressed as % of controls (=neutrophils + 0.1% dimethyl sulphoxide without ionophore). *b*, Effect of manipulation of $[Ca^{2+}]_i$ on the initial rates of ingestion of C3b-opsonized endotoxin-coated oil particles in Ca^{2+} free medium + 1 mM EGTA ($[Ca^{2+}]_0 = 10^{-9}$ M) The oil particles were prepared and opsonized as described previously[18]; at the end of opsonization (15 min, 37 °C), 2 mM EGTA was added to the oil particles. The phagocytosis experiments were performed in the above medium containing 1 mM Mg^{2+}, 1 mM EGTA but without Ca^{2+} ($[Ca^{2+}]_0 = 10^{-9}$ M). Phagocytosis was stopped by ice-cold isotonic NaCl + 1 mM *N*-ethylmaleimide + 2 mM EDTA, and the cells were washed twice in the same buffer. ▨, Phagocytosis in the presence of calcium by cells that were not loaded with quin2/AM. □, Phagocytosis by unloaded cells in the absence of extracellular calcium (Ca^{2+}-free medium + 1 mM EGTA) ($[Ca^{2+}]_0 = 10^{-9}$ M). It was 77% of the values obtained in medium containing 1 mM Ca^{2+}, and 72% of the cells ingested oil particles. ■, Phagocytosis by cells loaded with quin2/AM in Ca^{2+}-containing medium and tested in Ca^{2+}-free medium + 1 mM EGTA. ▩, Phagocytosis by quin2/AM cells, loaded and tested in Ca^{2+}-free medium + 1 mM EGTA. The intracellular quin2 concentration was 0.7 nmol per 10^6 cells. $[Ca^{2+}]_i$ in this last batch of cells was 8 nM, and no calcium could be released from intracellular stores by ionomycin. About 70% of the neutrophils contained oil droplets at the end of these four experiments after 10 min incubation.

phagocytosis, respectively. The IgG-coated yeast phagocytosis was inhibited by ~60% by preincubation of the neutrophils with the Ca^{2+} ionophore ionomycin, whereas C3bi-mediated yeast phagocytosis was completely unaffected by this treatment. Ionomycin at this concentration increases $[Ca^{2+}]_i$ to >1 μM (not shown, see ref. 13) and should abolish any existing localized $[Ca^{2+}]_i$ transient.

Our main conclusion is that two main mechanisms of phagocytosis seem to operate in human neutrophils First, C3b/bi-mediated phagocytosis, which occurs independently of $[Ca^{2+}]_i$, enabling phagocytosis, a motile event requiring a rearrangement of contractile proteins[6], to occur without the involvement of calcium ions. Other signals which trigger the contractile machinery must therefore exist. Whether latex particle ingestion occurs through a similar mechanism remains to be established. The elevation in $[Ca^{2+}]_i$ induced by C3bi-coated yeast should thus be considered a secondary event probably not directly related to phagocytosis. Second, Fc receptor-mediated phagocytosis, which possibly requires localized changes in $[Ca^{2+}]_i$ and depends on the presence of this ion at least at physiological concentrations in the cytosol. The reduction, but not complete inhibition, of IgG-mediated phagocytosis by high quin2 loading or ionomycin in Ca^{2+}-containing medium suggests that Fc-mediated phagocytosis may occur, at least in part, through a mechanism that does not require major changes in $[Ca^{2+}]_i$. However, we cannot eliminate the possibility that discrete local changes in $[Ca^{2+}]_i$ close to the plasma membrane are sufficient to trigger some ingestion, or that some IgG-independent ingestion of the yeast particles may occur.

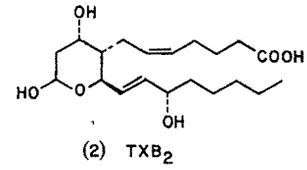
Synthesis and structure of the platelet aggregation factor thromboxane A_2



Shripad S. Bhagwat, Philip R. Hamann, W. Clark Still*, Stuart Bunting & Frank A. Fitzpatrick†

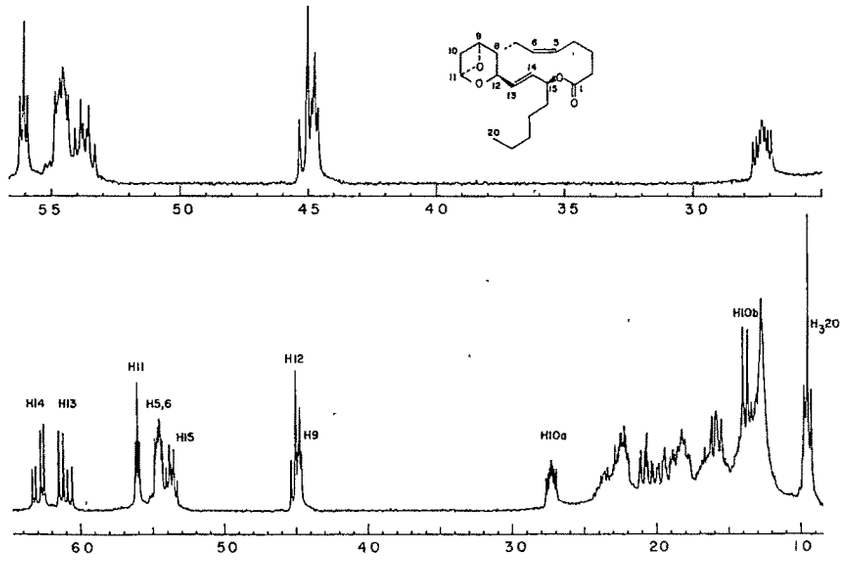
* Department of Chemistry, Columbia University, New York, New York 10027, USA
† Lipids Research, The Upjohn Company, Kalamazoo, Michigan 49001, USA

In 1975, Hamberg *et al.*[1] reported evidence for the existence of an unstable platelet-aggregating factor which they named thromboxane A_2 (TXA_2) and for which they proposed a novel bicyclic oxetane structure (1, below) based on the short half-life of the factor ($t_{1/2}$(37 °C) = 32 s at *p*H 7.4) and the isolation of degradation products related to thromboxane (TXB_2) (2, below). As natural TXA_2 has not yet been isolated and characterized as a pure compound, we have synthesized the proposed structure (1) from TXB_2 and compared its biological properties with those of authentic, biologically generated material. Here we present evidence that synthetic material having structure (1) is indistinguishable from platelet-derived TXA_2 in various biological assays and that the proposed structure (1) for TXA_2 is correct.

(1) TXA_2

(2) TXB_2

The acid-lability of TXA_2 is believed to be a result of the highly strained nature of the bicyclic oxetane acetal nucleus and it was only recently that the hetero-unsubstituted ring system, a 2,6-dioxabicyclo[3.1.1]heptane, was isolated[2]. (References 3-6 describe the preparation of heterosubstituted derivatives.) Bhagwat *et al.*[2] prepared the TXA_2 model (3) by a modified Mitsunobu[7] etherification [$(MeO)_3P$, $EtO_2CN{=}NCO_2Et$, CH_2Cl_2] of compound (4), followed by mild free-radical reduction (Bu_3SnH, C_6D_6, sun-lamp irradiation) and, auspiciously, (3)



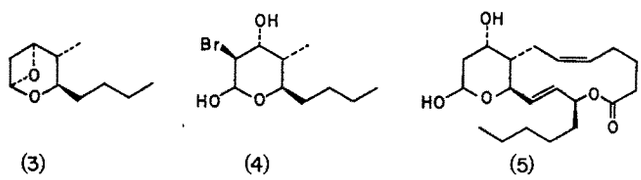


Fig. 1 270-MHz ^{1}H-NMR spectrum of synthetic 1,15-anhydro-TXA_2 in benzene-D_6. The lower trace shows the complete spectrum, with assignments being confirmed by double-resonance decoupling studies. The upper trace shows the expanded spectrum segment spanning 2.5–5.7 p.p.m.

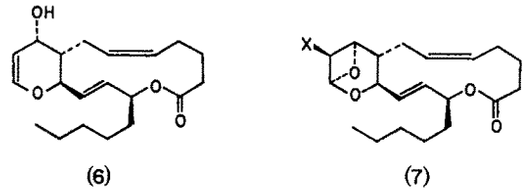

was found to undergo hydrolysis in the Krebs medium[8] at a rate comparable with that reported for TXA_2.

To prepare compound (1) by an analogous procedure, problematic C_{10} free-radical cyclization onto the C_{13}, C_{14} olefin in the penultimate precursor of (1) had to be avoided. This undesired reaction pathway could be eliminated by forming a conformationally restricted 1,15-macrolactone which prevented approach of the C_{13}, C_{14} olefinic linkage to the C_{10} free-radical intermediate in the debromination reaction. Thus, TXB_2 was converted to the 1,15-macrolactone (5) using the Corey-Nicolaou procedure (refs 9, 10 and see also refs 11–13), then dehydrated to the β-hydroxy enol ether (6) using 2-chloro-1-methylpyridinium iodide[14]. Formation of bromohydrin (*N*-bromosuccinimide, 1% $NaHCO_3$, H_2O/Et_2O; 51% yield overall from TXB_2) and oxetane [$(MeO)_3P$, $EtO_2CN{=}NCO_2Et$, CH_2Cl_2; 20% yield] then yielded 1,15-anhydro-10-bromo-TXA_2 (7, X=Br). Finally, polymer-bound tin hydride[15] reduction and filtration of the tin reagent gave the crystalline, acid-labile 1,15-anhydro-TXA_2 structure (7, X=H, melting point (pentane) = 81–82 °C) in high yield. Compound (7) (X=H) displayed the characteristic bicyclic oxetane ^{1}H- and ^{13}C-NMR resonances which closely matched those of compound (3) (the 270-MHz ^{1}H-NMR spectrum is shown in Fig. 1). The novel bicyclic oxetane structure of compound (7) was confirmed by single-crystal X-ray crystallography.

Although macrolide (7, X=H) did not show the biological properties of TXA_2, it was saponified in $NaOD/D_2O/CD_3OD$ (30 min, 22 °C) as evidenced by ^{1}H-NMR, which showed opening of the 1,15-macrolactone with retention of the bicyclic oxetane nucleus, to yield the synthetic compound (1) (TXA_2S) as its sodium salt, which did show the biological properties of

(3) (4) (5)

(6) (7)

TXA_2. TXA_2S was also prepared by saponification of compound (7) (X=H) with Me_3SiOK[16] in tetrahydrofuran and isolated as an amorphous solid by solvent evaporation. Although TXA_2S underwent rapid decomposition in neutral or acidic solutions, it was relatively stable in the basic saponification solutions described and could be stored for up to 1 week at −20 °C without significant loss of activity.

TXA_2S at concentrations of 16–100 ng ml^{-1} caused a concentration-dependent aggregation of human platelet-rich plasma (PRP). Irreversible aggregation occurred with 50–100 ng TXA_2S per ml for all cases examined. TXA_2S was found to be ~10 times more potent than the prostaglandin endoperoxide PGH_2 at inducing aggregation of human PRP. These comparative potencies (shown in Fig. 2) agree with published data[17,18]. TXA_2S (10 μg ml^{-1}) decayed in human plasma with first-order kinetics, with a half-life of 3.9 min at 37 °C, consistent with values of 3 min[19] and 5–6 min[20] determined by indirect methods for biologically generated material. The aggregatory effects of TXA_2S were confined to platelets. At 2 μg ml^{-1} it did not aggregate human neutrophils nor did it stimulate formation of leukotriene B_4.

A selective thromboxane synthetase inhibitor with no accompanying receptor-level antagonist properties (9,11-iminoepoxy-prosta-5,13-dienoic acid, U-54701) at 5–15 μg ml^{-1} had no effect on platelet aggregation induced by TXA_2S. In contrast, a related compound with receptor-level antagonist properties (9,11-diazo-prosta-5,13-dienoic acid, U-51605) at 1–3 μg ml^{-1} inhibited TXA_2-induced aggregation in a concentration-dependent manner[21].

Hydrolysis of TXA_2S in 0.1 M phosphate buffer, *p*H 7.4, eliminated its biological activity and produced a substance that was immunologically indistinguishable from synthetic TXB_2. Radioimmunoassay determinations of hydrolysed TXA_2S yielded values of 84±21, 60±16, 39±11 and 25±8 pg TXB_2 (mean±s.d. at 95% confidence level, $n=3$) which correspond to the predicted values of 125, 62, 31 and 15 pg, respectively. The half-life of TXA_2S at 37 °C in Krebs solution, measured by bioassay on vascular tissue, was 30 s, which corresponds closely to previously reported half-lives for biologically generated material[1,17].

The substance that induces contraction of rabbit aorta, detected by Piper and Vane[22] in the effluent of perfused guinea pig lung during anaphylaxis, was shown to be a mixture of TXA_2 and prostaglandin endoperoxides. Similarly, TXA_2 generated by platelets or a partially purified platelet enzyme, has potent vascular contracting activity. Thus, both natural and synthetic TXA_2 contracted all vascular tissue tested including Krebs-superfused[23] rabbit aorta, pulmonary, mesenteric and coeliac arteries and bovine coronary arteries. On most tissues,

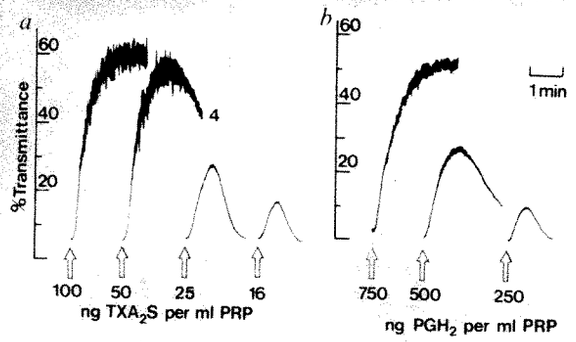

Fig. 2 Dose-response curves for aggregation of platelets in human platelet-rich plasma (PRP) for synthetic (*a*) and biologically generated (*b*) TXA_2. Whole blood (45 ml) was collected over 3.8% w/v trisodium citrate (5 ml). PRP (20 ml) was isolated from blood after centrifugation at 200*g* for 10 min at 25 °C. PRP suspensions (1.0 ml) were incubated at 37 °C for 2 min, then transferred to an aggregometer cuvette containing TXA_2S (10–200 ng) or prostaglandin endoperoxide PGH_2 (100–1,000 ng). Platelet suspensions were stirred at 1,100 r.p.m. at 37 °C and aggregation was monitored as described by Born[25]. To verify that the effects were attributable solely to exogenous TXA_2 or PGH_2, and to exclude any contribution to aggregation from activation of endogenous arachidonic acid metabolism, PRP containing 250 μM aspirin was used.

2–3 ng of TXA_2S was the threshold dose for contraction, generating ~200 mg of tension, with higher doses generating more than 2 g of tension in rabbit aorta and 4 g of tension in bovine coronary arteries. The potency of TXA_2S compared well with the activity of biologically produced TXA_2, calculated from the amount of PGH_2 originally in the incubation (assuming 100% conversion). Rabbit mesenteric and coeliac arteries respond to PGH_2 with a small, short-lived contraction, followed by larger, longer-lasting relaxation[24], whereas TXA_2S and biologically generated TXA_2 gave only constriction.

Although these experiments do not exclude the formal possibility that compound (1) is not TXA_2 itself but is converted *in vivo* to a different material which is the endogenous TXA_2, the qualitative and quantitative activity and the half-life of TXA_2S provide strong evidence that the Samuelsson[1] oxetane structure (1) for TXA_2 is correct.

The synthetic work described here was carried out by S.S.B., P.R.H. and W.C.S. at Columbia University. These authors thank Dr John Pike of the Upjohn Company for a generous supply of TXB_2 and the NIH for support (HL25634). Biological studies were carried out by S.B. and F.A.F. at the Upjohn Company.

Tissue localization and chromosomal assignment of a serum protein that tracks the cystic fibrosis gene

Veronica van Heyningen, Caroline Hayward*, Judy Fletcher & Christine McAuley*

MRC Clinical and Population Cytogenetics Unit and *Human Genetics Unit, Western General Hospital, Edinburgh EH4 2XU, UK

The basic gene defect in the autosomal recessive disorder cystic fibrosis has not been identified, and no firm linkage of the disorder to any other marker has been reported. However, a serum protein abnormality present in unaffected heterozygotes as well as in affected homozygotes has been described[1], and immunological quantitation of this protein, termed cystic fibrosis antigen, allows the three genotypes to be distinguished[2,3]. We show here that an immunologically indistinguishable protein is present at high concentrations in granulocytes from normal and cystic fibrosis individuals as well as in myeloid leukaemia cells. Somatic cell hybrids between the mouse myeloid stem-cell line WEHI-TG and myeloid leukaemia cells express cystic fibrosis antigen only when human chromosome 1 is present.

Cystic fibrosis is one of the most common serious genetic diseases in Caucasian populations: 1 in 2,000 live births produces an affected child. Assuming that homozygosity for mutant allele(s) at a single locus gives rise to affected individuals[4], the expected heterozygote frequency in these populations is about 1 in 22. The major abnormalities are those of exocrine secretion[5]. Raised sweat sodium and chloride concentration is currently the best diagnostic test for the disease[6], but clinical problems arise because of chronic obstructive lung disease and exocrine pancreatic insufficiency leading to malabsorption and neonatal intestinal blockage[5]. Despite much effort to define the basic gene defect, no obvious candidate has been found among the many, mainly secondary, observed metabolic abnormalities. Therefore, the study of any abnormality which is manifested in a gene dosage-dependent manner in the symptomless obligate heterozygote as well as in the affected homozygote may lead to the identification of a primary defect and hence to the aberrant gene in cystic fibrosis[7].

We have followed a serum protein first described by Wilson *et al.*[1] as a doublet band at *p*I 8.4 on isoelectric focusing (IEF) in the presence of urea. This doublet band is present in serum from cystic fibrosis homozygotes and heterozygotes but not in normal serum, a finding confirmed by several other groups[8–10]. Manson and Brock[2] produced a guinea pig antiserum to the doublet band cut out of IEF gels. When used in rocket immunoelectrophoresis, this antiserum distinguishes all three genotypes: homozygotes have high, heterozygotes intermediate and normals very low (or absent) concentrations of this protein, cystic fibrosis antigen. But the exact method of serum collection is critical for accurate quantitation of the antigen and hence for heterozygote detection. The performance of the rocket assay on optimally collected serum samples is described by Bullock *et al.*[3]. Blood from normal individuals collected in the presence of the serine protease inhibitor benzamidine exhibits high levels of cystic fibrosis antigen. Heparin- or EDTA-collected plasma samples, on the other hand, possess antigen levels expected on the basis of genotype, but produce poor rockets.

Attempts have been made to purify the antigen to identify it biochemically and to produce monoclonal antibodies which would improve and simplify the heterozygote detection technique, but with increasing purification the antigen was repeatedly lost. Partial purification by gel-permeation on Sephacryl S-300, however, is possible. The antigen can be recovered in fractions strongly contaminated with albumin, suggesting that it has a relative molecular mass of ~70,000. To attempt to eliminate this contamination, several probable tissue and cell

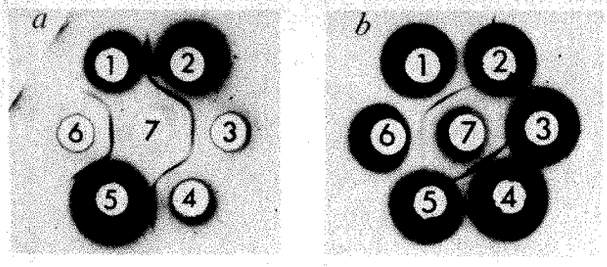

Fig. 1 Ouchterlony double-diffusion analysis for the presence of cystic fibrosis antigen. *a*, 1, Pooled sera from 15 cystic fibrosis homozygotes; 2, guinea pig antiserum raised against material cut out of the cystic fibrosis-specific doublet band region of IEF gels[1] (GP anti-IEF); 3, guinea pig antiserum raised against partially purified antigen from myeloid leukaemia cells (GP anti-CML); 4, antiserum raised as in 3, but in rabbit; 5, citrated plasma from a cystic fibrosis patient; 6, GP anti-CML; 7, freeze-thawed, spun lysate in Dulbecco A buffer of peripheral leukocytes (at 10^8 cells per ml) from a CML patient who was the human parent in the WEMAD hybrids. *b*; 1–5, Cell lysates prepared as for the CML cells above. 1, WEMAD 1.1.9.1; 2, WEMAD 1.1.6.3; 3, NYX 3.1 (see text); 4, WEH 3127.6.1; 5, WEP 1342.2.3; 6, cystic fibrosis serum pool; 7, GP anti-IEF. For assessment of antigen status see Fig. 2. Wells contained 10 μl of appropriately diluted antiserum or antigen. Diffusion was carried out for 24 h at room temperature in 1.5% Difco Noble agar in Dulbecco A buffer containing 0.02% azide; the gels were washed extensively in buffer with 0.05% Tween 20, dried down on Gelbond and stained with Coomassie Blue.

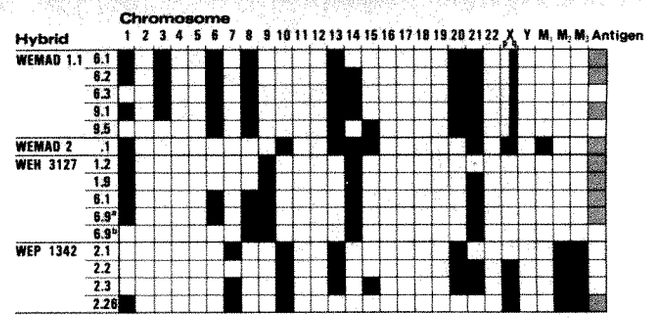

Fig. 2 The segregation of human chromosomes and cystic fibrosis antigen in subclones from a series of four independent hybrid lines between the mouse myeloid stem cell line WEHI-TG (ref. 11) and human myeloid leukaemia cells. Filled squares denote the presence of human chromosome in >30% of karyotyped cells (>16 cells for each clone). Open squares denote the absence of the chromosome in >95% of cells. Each series of marked subclones (WEMAD 1, WEMAD 2, WEH and WEP) is derived from a hybrid line which arose from an independent fusion event. Fusion was effected between leukaemic cells and WEHI-TG (at 10:1 ratio) with 0.5 ml 25% polyethylene glycol 1500 containing 1,250 haemagglutinating units of β-propriolactone-inactivated Sendai virus. Hybrid cells were selected for by selection using hypoxanthine-aminopterin-thymidine[13]. Independent hybrids arose in separate wells. Subcloning was by limiting dilution and carried out repeatedly until reasonable chromosomal stability was established. Subclones were then grown up so that cells within a few transfer generations were preserved in liquid nitrogen, pelleted for antigen assay and karyotyped by sequential trypsin banding[14] and Giemsa-11 staining[15]. The subclone WEH 3127.6.9 contained cystic fibrosis antigen and chromosome 1 was present in 32% of cells on first testing (a). Six transfer generations later (b) both the antigen and chromosome 1 were absent from WEH 3127.6.9. Unidentifiable human marker chromosomes M_1, M_2 and M_3 were found in some hybrids. None seemed to be derived from chromosome 1.

types were examined as potential antigen sources[5] by rocket immunoelectrophoresis and by immunodiffusion. Peripheral leukocytes from chronic myeloid leukaemia (CML) patients proved consistently to be strongly positive for cystic fibrosis antigen, and antigen from normal granulocytes was immunologically identical. It remains to be seen whether the presence of antigen in tissue lysates from adult liver, kidney and brain is caused by blood contamination of these tissues or whether it is intrinsic to tissue-specific cells. Lymphoblastoid cell lines from normal and cystic fibrosis individuals are antigen negative. Ouchterlony double diffusion demonstrates the immunological identity of cystic fibrosis antigen from serum and CML cells (Fig. 1*a*), and also shows that antiserum raised in rabbit and guinea pig against partially purified antigen from CML lysates detects the antigen in appropriate serum samples.

It has been shown previously that at least some human granulocyte-specific products are expressed in somatic cell hybrids between the mouse myeloid stem-cell line WEHI-TG and CML cells[11]. To observe segregation of cystic fibrosis antigen with a human chromosome, we produced a series of independent hybrid lines between WEHI-TG and cells from four different myeloid leukaemia patients. As soon as sufficient cells were available from each hybrid line, cell lysates were tested by Ouchterlony assay for the presence of antigen. (WEHI-TG and mature mouse granulocytes are negative in this assay). Negative and positive hybrids were subcloned repeatedly to achieve reasonable chromosomal stability. Subclones were assayed for cystic fibrosis antigen and analysed for the presence of human chromosomes within the space of one to three transfer generations. Figure 1*b* shows the clear-cut results seen with these hybrid lines as long as the equivalence point between each cell lysate and the guinea pig antiserum was predetermined by previous titration. The results of the complete segregation analysis on 15 subclones from 4 independent hybrid lines are summarized in Fig. 2. Antigen segregates with human chromosome 1 with complete concordance. No other chromosome is consistently present with this antigen, suggesting that the structural gene for this protein is on chromosome 1. Note that NYX 3.1 (a mouse myeloma × human B-lymphoblastoid line somatic-cell hybrid containing chromosome 1 at high frequency) does not express the antigen. This observation agrees with the notion that this serum protein is a differentiated cell product.

As with other autosomal recessive diseases, the defect in cystic fibrosis presumably results from the absence of a normal biological function which arises only if both copies of a gene are aberrant. Assuming that the accumulation of cystic fibrosis antigen is closely related to the basic genetic defect, what sort of mutation could account for the observed pattern: high, intermediate and zero serum levels, in cystic fibrosis homozygotes, heterozygotes and normals respectively, of a protein immunologically indistinguishable (with available antisera) from a normal granulocyte product?

Increased granulocyte fragility which might result from a membrane defect is an unlikely explanation because heterozygotes have increased antigen levels and yet are symptom-free. Suggestions that homozygote and heterozygote sera contain factor(s) which induce increased leukocyte degranulation[12] are not supported by our observation that serum levels of lactoferrin (a specific granule protein) are unaffected by cystic fibrosis gene status (D. Brock, S. Chung and V. van H., unpublished). Another possibility is that a protein that is routinely released into the circulation from granulocytes needs to be processed (for example, by proteolytic cleavage) to fulfil a normal biological function and in the course of this it becomes antigenically unrecognizable. The gene dose dependence of antigen level again makes it unlikely that the mutation resides in a processing enzyme as this would require the aberrant step in the processing sequence to be rate-limiting. The simplest explanation is that the accumulated protein itself is the product of the cystic fibrosis gene and it is altered so that it cannot be normally processed.

The probable site for the mutation, then, is a region of polypeptide chain which acts as a site for a specific proteolytic cleavage step, probably one of several sequential steps involved in releasing a biologically active product from a precursor. This scheme would explain the presence of the high level of antigen and the absence of an essential function in affected homozygotes. Heterozygotes, on the other hand, would possess one normally

processed copy of the cystic fibrosis gene and one mutant copy which would give rise to a half dose of the antigen.

Resolving the biochemical identity of the cystic fibrosis antigen should provide insight into the nature of the disease and allow critical assessment of the genetic hypothesis described here. We are attempting the immunological purification of the antigen, using low-affinity monoclonal antibodies, and are also screening for high-affinity antibodies which will permit the development of a more reliable heterozygote detection assay. Attempts are also in progress to isolate the cystic fibrosis antigen gene by complementary DNA cloning.

We thank Dr David Brock for encouragement and helpful discussion, Dr A. Geurts van Kessel for the gift of WEHI-TG cells, and Drs A. E. Dewar, C. A. Parkin, N. C. Allan, A. Birch and J. A. Raeburn for supplying blood samples. This work was supported in part by the Cystic Fibrosis Research Trust.

Human transforming growth factor-α causes precocious eyelid opening in newborn mice

Joseph M. Smith*, Michael B. Sporn*, Anita B. Roberts*, Rik Derynck†, Marjorie E. Winkler† & Harry Gregory‡

* National Cancer Institute, NIH, Bethesda, Maryland 20205, USA
† Genentech, Inc., South San Francisco, California 94080, USA
‡ ICI Ltd, Pharmaceuticals Division, Alderley Park, Macclesfield, Cheshire SK10 4TG, UK

Both murine and human epidermal growth factors (EGFs) are known to cause precocious opening of the eyelids in newborn mice[1-3]. Another set of peptides that are structurally and functionally homologous to murine and human EGFs are the murine and human type-α transforming growth factors (TGF-αs)[4-7]. TGF-αs have been found in many cancer cells and it has been suggested that their autocrine action may play an important part in malignant transformation[8-11]. In several *in vitro* systems murine and human TGF-αs are functionally interchangeable with murine and human EGFs[6,12-14]. However, the *in vivo* activity of the TGF-αs has not been characterized, as only small amounts of these peptides were available until recently. The cloning of the gene for human TGF-α and its expression in *Escherichia coli*[6] now allow us to demonstrate that human TGF-α is as active as murine EGF in promoting eyelid opening in newborn mice. Furthermore, we show in a dose-dependent eyelid opening assay that human EGF is as potent as its murine homologue with respect to this biological property.

The original discovery and purification of murine EGF[1] was based on the measurement of the intrinsic ability of this molecule to accelerate eyelid opening as its primary activity. This property formed the basis for the discovery of the identity of human urogastrone and human EGF and their functional as well as structural homology to murine EGF[2,3]. TGF-αs were first described in retrovirus-transformed cells[8] and have subsequently been found to be secreted by a wide variety of rodent and human tumour cells, suggesting that aberrant expression of these peptides has a role in transformation. It has been speculated that TGF-α functions as an embryonic form of EGF, but it is uncertain what physiological role, if any, TGF-α has in post-embryonic life. Both rat and human TGF-αs have recently been isolated as pure substances and their amino-acid sequences determined[4-7]; they have significant homologies with mouse and human EGFs, particularly with regard to the location of their six cysteine residues, which are important determinants of molecular shape through the formation of disulphide bridges. Human and murine EGF and TGF-α all bind to a common receptor, generally referred to as the EGF receptor, and the qualitative and quantitative activity of all four peptides in many *in vitro* assays is essentially the same[6,13-16].

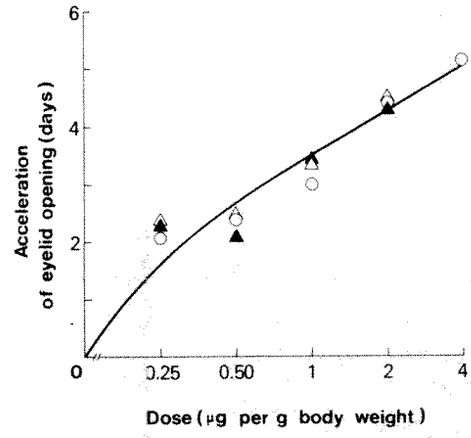

Fig. 1 Dose-response curve for activity of human TGF-α (▲), human EGF (△) and mouse EGF (○) in accelerating eyelid opening in newborn Swiss mice.

In the experiments reported here, 315 newborn mice were injected with human TGF-α, human EGF, mouse EGF or the vehicle for the growth factors (phosphate-buffered isotonic saline, PBS) as a control. Each of the three growth factors was shown to be pure by its unique amino-acid composition, particularly by the absence of specific amino acids. Human TGF-α

Table 1 Acceleration of eyelid opening by TGF-α and EGF

Dose (μg)	Mouse EGF	Human EGF	Human TGF-α
4.0	8.8 ± 0.2 (4)		
2.0	9.6 ± 0.1 (35)	9.4 ± 0.1 (21)	9.6 ± 0.3 (18)
1.0	10.9 ± 0.1 (20)	10.6 ± 0.1 (18)	10.5 ± 0.2 (21)
0.50	11.5 ± 0.1 (16)	11.4 ± 0.1 (18)	11.8 ± 0.2 (18)
0.25	11.8 ± 0.2 (12)	11.5 ± 0.1 (15)	11.6 ± 0.1 (18)
Control	13.9 ± 0.1 (81)	13.9 ± 0.1 (81)	13.9 ± 0.1 (81)

Values shown are the mean day of eyelid opening ±s.e.; values in parentheses are the numbers of mice treated at each dose level. The doses are per g body weight. The data from four experiments, all of which yielded similar results, were pooled. Newborn mice were treated with growth factors dissolved in PBS or with PBS alone, as described in the text. The doses for the three growth factors were adjusted to be equivalent to a murine EGF standard, as measured[18] by the ability of each peptide to compete with ^{125}I-labelled EGF for binding to cell-surface receptors in normal rat kidney fibroblasts (NRK 49F). Based on amino-acid analysis, the amount of TGF-α per binding equivalent was fourfold greater than that of either mouse or human EGF. The effects of all dosages of TGF-α and both EGFs are significantly different from the controls (Student's t-test; $P < 0.001$). There are no significant differences between the effects of the three peptides themselves at any given dose; $P > 0.5$.

was purified by passage through Sephadex G-75 and HPLC after expression of the cloned gene in *E. coli*[6]; the material used was essentially free of other proteins, as shown by the absence of isoleucine and methionine on amino-acid analysis. Human EGF was obtained by chemical synthesis of the gene for this peptide[17], followed by expression of the gene in *E. coli*[17]. The expressed precursor protein (provided by G. D. Searle) was cleaved with trypsin to give the exact human sequence, and the cleaved protein was isolated by ion-exchange and gel chromatography. The purity of this peptide was demonstrated by HPLC in three systems, by acrylamide gel electrophoresis, and by the absence of threonine and phenylalanine on amino-acid analysis. Mouse EGF was prepared by acid/ethanol extraction of salivary glands, followed by gel filtration, DEAE-cellulose chromatography, and HPLC[18], which is a modification of the procedure of Savage and Cohen[19]. The purity of the murine EGF was shown by the absence of alanine, lysine and phenylalanine from the final material.

Newborn Swiss mice were injected daily, beginning at 1 day old, with one of the three growth factors or with a PBS control. All injections were made subcutaneously, in the nape of the neck, in a volume of 10 μl per g body weight. Each litter of nine mice was divided into three groups, which received different doses of the same growth factor, or the same dose of each of the three growth factors. Each mouse was treated for eight consecutive days; the doses used are shown in Table 1. Figure 1 and Table 1 show that human TGF-α, and human and murine EGF all accelerate normal eyelid opening, and that the effect is dose-responsive, except at the very lowest dose used. Moreover, the response of the newborn mouse to the three different peptides is essentially identical.

In another set of experiments (data not shown) we found that transforming growth factor-β (TGF-β), isolated from human blood platelets[20] and used at a dose of 400 ng per g body weight, either alone or in combination with murine EGF, had no activity in the eyelid opening assay. TGF-β has been shown to be a potent synergist of EGF in promotion of the growth of non-neoplastic rat fibroblasts in soft agar[7,12,20].

Although the activity of human EGF in this eyelid opening assay has been described previously in tests involving small numbers of mice[2,3], the present data show definitively for the first time that the respective human and murine peptides are essentially identical in this regard. Furthermore, the almost identical activity of TGF-α and the two types of EGF suggests that the *in vivo* response to all three peptides involves a common, receptor-mediated pathway, much as has been shown for their effects *in vitro*. The equivalence of these peptides *in vivo* is all the more remarkable considering that pharmacokinetic phenomena such as absorption, transport and half-life are also involved. Finally, the data are of interest in that they show that a defined peptide growth factor, generally associated with the malignant behaviour of cells, may have a benign physiological activity that is indistinguishable from related molecules found in non-malignant tissues.

We thank Stanley Cohen for originally suggesting these experiments, Richard Assoian for amino-acid analysis of the three peptides, and Stephen Dalton and Sue Perdue for secretarial assistance.

Expression of c-*mos* proto-oncogene transcripts in mouse tissues

Friedrich Propst & George F. Vande Woude

Molecular Mechanisms of Carcinogenesis Laboratory, LBI-Basic Research Program, NCI-Frederick Cancer Research Facility, Frederick, Maryland 21701, USA

Valuable information about proto-oncogenes and their physiological function has been obtained by studying their expression in normal cells. However, expression of the c-*mos* gene, the cellular homologue of the transforming gene of Moloney murine sarcoma virus[1,2], has not been detected in normal mouse cells or tissues[3–6]. The conservation of the c-*mos* open reading frame[7–9] strongly indicates that the gene must function during some portion of the animal life cycle, and other lines of evidence[10–15] suggested to us that the c-*mos* proto-oncogene may be expressed at very low levels in normal tissues. We have used a sensitive S_1 nuclease assay to screen RNA preparations from mouse tissues and describe here the detection of c-*mos*-related transcripts especially in mouse embryos, testes and ovaries. The transcripts found in testis RNA are estimated to be ~1.7 kilobases (kb) long by Northern analysis. S_1 analysis demonstrates that the entire *mos* open reading frame is present. In contrast, we detect ~1.4-kb transcripts in ovary RNA and at least two major transcripts, ~2.3 and ~1.3 kb, in embryo RNA. The latter transcripts have in common sequences of at least 1 kb, representing most of the c-*mos* open reading frame. The variation in size of the *mos* transcript in different tissues suggests a novel regulatory mechanism for the expression of this proto-oncogene.

In the present study, we have examined mouse tissues for c-*mos* expression using S_1 nuclease[16,17]. An internal fragment

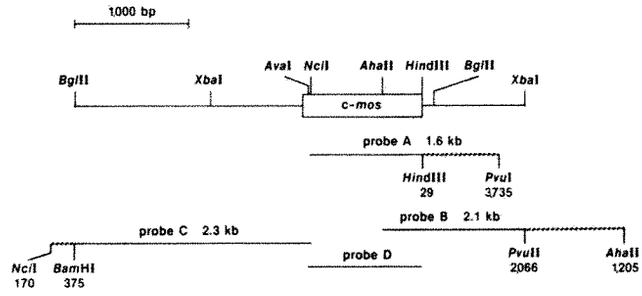

Fig. 1 Restriction fragment probes derived from the mouse genomic c-*mos* locus. Relevant restriction sites are shown. Wavy lines represent pBR322 sequences (restriction sites and their sequence position are given below the line). Probe A, 3′ end-labelled at *Ava*I; probe B, 3′ end-labelled at *Aha*II; probe C, 5′ end-labelled at *Nci*I; and probe D, *Ava*I/*Hin*dIII fragment labelled by nick-translation.

Methods. All probes were derived from appropriate subclones of c-*mos* sequences in pBR322; 3′ end-labelling was carried out with the Klenow fragment of *Escherichia coli* DNA polymerase (Boehringer) in the presence of the appropriate [α-^{32}P]-labelled deoxynucleotides (3,200 Ci mmol^{-1}; NEN) required to fill-in the respective restriction site as described elsewhere[20], except that labelling was done in the presence of 240 mM NaCl. 5′ End-labelling was carried out using polynucleotide kinase (Boehringer)[20,23] and [γ-^{32}P]ATP (7,000 Ci mmol^{-1}, NEN). The *Ava*I/*Hin*dIII fragment for probe D was gel-purified and nick-translated as described elsewhere[24].

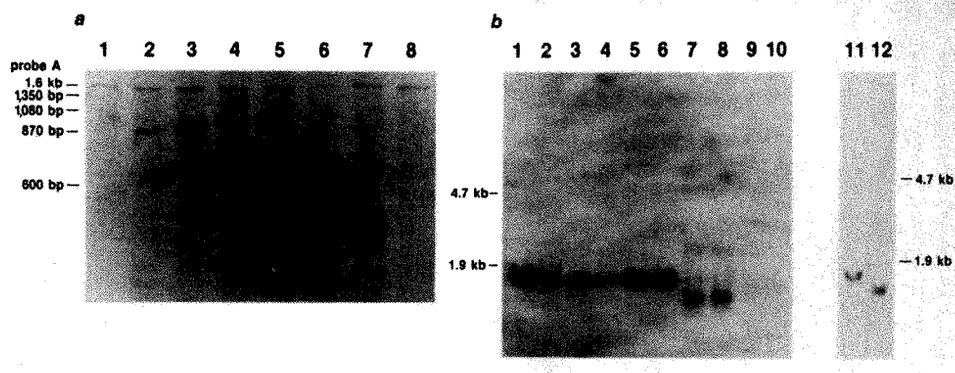

Fig. 2 Detection of transcripts homologous to c-*mos*. *a*, S_1 analysis using probe A. Lane 1, 25 μg of yeast transfer RNA; lane 2, 2.5 μg of total RNA from a NIH 3T3 cell line transformed by pm13 plus 25 μg of total NIH 3T3 cell RNA; lane 3, 50 μg of total embryonic RNA; lane 4, 5 μg of embryonic poly(A)$^+$ RNA plus 25 μg of yeast RNA; lanes 5–8, 25 μg of total RNA from, respectively, liver, kidney, brain and skin. The samples were hybridized to probe A at 60 °C overnight as described [16,17], followed by digestion at 37 °C for 45 min[16,17] with single-strand-specific S_1 nuclease (10,000 U ml^{-1} final concentration; Boehringer). Samples were then analysed by electrophoresis on a 5% denaturing polyacrylamide gel, which was then dried and exposed to X-ray film (XAR-5; Kodak) at −70 °C for 20 h in the presence of an intensifying screen. In this analysis a small amount of self-annealing probe is detected at 1.6 kb. *b*, Northern analysis using probe D. Lane 1, 25 μg total testis RNA; lane 2, 25 μg testis RNA (fraction not bound to oligo(dT) cycle 1); lane 3, 2 μg testis RNA (fraction bound, cycle 1); lane 4, 2 μg testis RNA (fraction not bound, cycle 2); lane 5, 2 μg testis RNA (fraction bound, cycle 2); lane 6, 2 μg testis RNA (fraction bound, cycle 3); lane 7, 10 μg male embryo poly(A)$^+$ RNA; lane 8, 10 μg female embryo poly(A)$^+$ RNA; lane 9, 25 μg total male embryo RNA; lane 10, 25 μg total female embryo RNA; lane 11, 25 μg total testis RNA; lane 12, 25 μg total ovary RNA. Samples 1–10 and 11–12, respectively, were electrophoresed on separate agarose formaldehyde gels and transferred to nitrocellulose as described elsewhere[25–27]. Hybridization was carried out at 42 °C in 50% formamide[20], then the blots were exposed to X-ray film (XAR-5; Kodak) for 3 days. RNA preparation: Animals were killed by cervical dislocation and the various organs were removed. Embryos for the experiment in *a* (and in Fig. 3*a*) were a mixture from nine different inbred strains removed 1 day before birth. The BALB/c embryos for the experiment in *b* were removed at day 19 of gestation. In each case the embryo was completely separated from extra-embryonal membranes and the placenta. For the experiment in *b*, embryos were sexed by microscopic examination of the gonads. Testes and ovaries were taken from 34–39-week-old BALB/c breeders. Routinely, specific organs from several animals were pooled before homogenization, for example, testes from 10–15 mice. The tissue was homogenized immediately or frozen on dry ice and kept at −70 °C for later homogenization (using a mortar and pestle) to a fine powder. Fresh tissue and the frozen powder were then homogenized in a Dounce homogenizer in 5 M guanidinium isothiocyanide, 0.1 M mercaptoethanol and total RNA was prepared as described elsewhere[20,28,29]. In *a*, poly(A)$^+$ RNA was prepared as described elsewhere[20]; the same poly(A)$^+$ RNA selection procedure was used for *b*, except that oligo(dT) columns were not washed with low-salt buffer after loading.

of mouse c-*mos* was radioactively end-labelled with all four deoxynucleotides and used as a probe (probe A, Fig. 1). This probe was then used to screen for *mos*-containing transcripts in total or poly(A)$^+$ RNA extracted from a variety of adult mouse tissues and embryos (Fig. 2*a*). As a positive control for the S_1 assay, we used total RNA extracted from NIH 3T3 cells transformed by pm13, a recombinant DNA clone that contains v-*mos*; this cell line was estimated to contain 1–10 copies of v-*mos* RNA per cell[10,11]. *mos*-Specific transcripts were detected in a 10-fold dilution of total RNA prepared from these transformed cells (Fig. 2*a*, lane 2).

Probe protection was clearly observed in RNA prepared from mouse testes, ovaries (see below) and embryos (Fig. 2*a*, lanes 3 and 4), the size of the protected fragment corresponding to the distance between the *Ava*I and *Hin*dIII sites (925 base pairs, bp) in c-*mos*. RNA from pm13-transformed NIH 3T3 cells protects a somewhat smaller fragment (Fig. 2*a*, lane 2) because the 3′ end of this particular v-*mos* gene differs from that of c-*mos*[18,19]. To exclude the possibility that contamination by DNA of total RNA, especially testis RNA, was responsible for protection of the 925-bp fragment, we performed reconstruction experiments with unlabelled homologous c-*mos* DNA fragments (not shown) or subjected samples to digestion with DNase or RNase before the assay. The hybridization conditions were chosen to favour RNA/DNA hybrid formation (as opposed to DNA/DNA hybrids). RNase but not DNase treatment prevented the detection of the ~925-bp band (not shown). We have variably observed protection of the ~925-bp c-*mos* band in S_1 analyses of total RNA from epididymis, kidney, brain and placenta, but the low amounts detected in these preparations were not analysed further. We did not detect similar bands in total RNA prepared from liver or skin (Fig. 2*a*, lanes 5 and 8), spleen, thymus and intestine (not shown).

We observed that the concentration of c-*mos* RNA in testes, ovaries and embryos was equal to or higher than that in the pm13 control (compare lanes 1, 2 and 3 of Fig. 2*a*), suggesting that we should be able to identify the transcripts by Northern analysis. We detected discrete bands of ~1.7 kb in testis RNA (Fig. 2*b*, lanes 1–6 and 11), 1.4 kb in ovary RNA (Fig. 2*b*, lane 12) and ~1.3 and ~2.3 kb in embryonic poly(A)$^+$ RNA (Fig. 2*b*, lanes 7, 8). In these analyses, the poly(A)$^+$ RNA was prepared from either male (Fig. 2*b*, lane 7) or female (Fig. 2*b*, lane 8) embryos.

Comparison of the concentration of *mos* transcripts in total embryo RNA versus poly(A)$^+$ RNA (Fig. 2*a*, lanes 3 and 4) indicates that the oligo(dT) selection does not result in a significant enrichment of *mos* RNA. However, the same selection procedure[20] does enrich for c-*myc* transcripts (not shown). Even with decreased stringency conditions for poly(A)$^+$ RNA selection, a significant amount of *mos*-specific RNA is not bound to oligo(dT) (Fig. 2*b*, lanes 1 and 2). However, the fraction of *mos* transcripts which are bound in the first oligo(dT) selection (Fig. 2*b*, lane 3) continues to be selected through two additional cycles (lanes 4–6 of Fig. 2*b*); this suggests that the *mos* transcripts may have only short poly(A) tails and may help to explain some of the previous difficulties in detecting *mos* transcripts.

To characterize further the *mos* RNA expressed in testis and embryonic tissue, probes B and C (Fig. 1) were used with S_1 nuclease to determine the extent of protection of sequences downstream and upstream of the c-*mos* open reading frame. With both testis and embryonic RNA, a ~470-bp fragment from probe B was protected (Fig. 3*a*, lanes 1, 2 and 3 respectively). This result indicates that c-*mos* RNA extends 130 bp downstream from the c-*mos* termination codon and ends ~20 bp beyond a consensus poly(A) signal[9]. S_1 mapping of testis RNA with probe C yields two bands of ~400 and 450 bp (Fig. 3*b*, lane 1) corresponding to sites 260 and 310 bp upstream of the conserved *mos* initiation codon[21]. The DNA sequence in this region shows no obvious splice acceptor or promoter sites. However, it is just distal to a region called MUH[22], which is 75% conserved between human and mouse. These analyses demonstrate that the entire *mos* open reading frame plus 260 or 310 bp of upstream sequence and 130 bp of downstream sequence are present in the transcripts. The estimated length of the testis transcript is 1.7 kb by Northern analysis, but only ~1.4 kb can be accounted for by S_1 mapping. Thus, either the

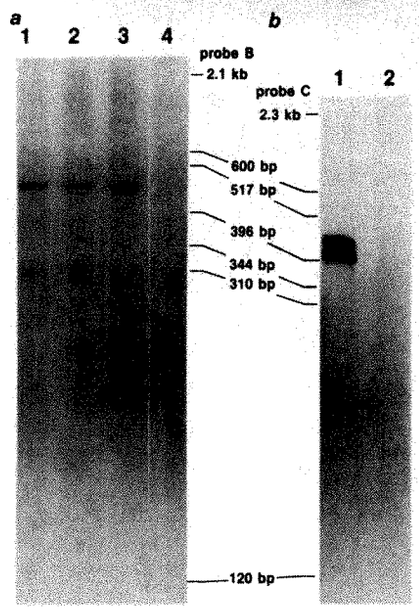

Fig. 3 S_1 nuclease mapping of *mos* transcripts. *a*, S_1 mapping using probe B. Lane 1, 25 μg total testis; lane 2, 2 μg of poly(A)$^+$ testis RNA plus 30 μg of yeast tRNA; lane 3, 3 μg of embryonic poly(A)$^+$ RNA plus 30 μg of yeast tRNA; lane 4, 30 μg of yeast tRNA. The samples were hybridized to probe B at 60 °C overnight. *b*, S_1 mapping using probe C. Lane 1, 25 μg of total testis RNA; lane 2, 30 μg of yeast tRNA. The samples were hybridized to probe C at 52 °C overnight. For analysis of DNA/RNA hybrids and preparation of RNA samples, see Fig. 2 legend. The X-ray film (XAR-5; Kodak) was exposed for 14 days at −70 °C in the presence of an intensifying screen.

transcript size is overestimated by Northern analysis or there is RNA processing 5′ and/or 3′ to the protected regions.

While the embryonic RNA transcripts protect a discrete ~925-bp fragment of probe A (Fig. 2*a*, lanes 3 and 4) and a ~480-bp fragment of probe B (Fig. 3*a*, lane 3), they do not give a detectable signal with probe C (not shown), indicating that they differ from the testis RNA transcripts in the region 5′ to the *mos* ATG. Similarly, S_1 mapping of the ovarian RNA transcripts indicates that they also differ from both the testis and embryo transcripts at the 5′ end (not shown). Collectively, these results suggest that transcripts from the single-copy *mos* locus are expressed in a tissue-specific manner. In addition, these transcripts are either promoted from different sites and/or are spliced differently in testes, ovaries and embryonic tissues.

We have shown that c-*mos* is not efficiently activated by a downstream long terminal repeat (in contrast to v-*mos*[1]); this has been attributed to the presence of an upstream transcription termination sequence termed UMS[21] (M. L. McGeady and G.F.V.W., in preparation) and to the lack of a promoter between UMS and c-*mos* that can function in NIH 3T3 cells[21]. How then can *mos* be expressed? One suggestion[21] is that *mos* expression can be *trans*-activated. The presence of *mos* transcripts in tissues like testes and ovaries may indicate a *trans*-activation mechanism mediated by hormonal control. We also note that an additional 60 codons are proximal to the conserved *mos* ATG in all three *mos* genes that have been sequenced[8,22]. Thus, in addition to tissue-specific regulation of the size of the *mos* transcripts expressed, the presence or absence of these codons (or possibly other exons) could give rise to functionally different protein products in specific tissues.

Finally, the higher levels of *mos* expression detected in gonadal tissues and the differences in transcript size between ovaries and testes suggest that *mos* proto-oncogene expression is regulated in a sex-linked manner and may be associated with expression of primary and/or secondary sex-related phenotypes.

This research was sponsored by the National Cancer Institute, DHHS, under contract NO1-CO-23909 with Litton Bionetics, Inc.

Note added in proof: We have also detected a 6-kb *mos* transcript in poly(A)$^+$ RNA from embryos and epididymis. In addition, *mos* transcripts are present in rat embryos and testes.

Does interocular transfer occur in visual navigation by ants?

R. Wehner & M. Müller
Nature **315**, 228-229 (1985)

The third sentence of the last column on page 229 should read "In honey bees, IOT has been inferred . . ."

Identification and comparison of two sequence elements that confer cell-type specific transcription in yeast

A. M. Miller, V. L. MacKay & K. A. Nasmyth
Nature **314**, 598-603 (1985).

In the eighth line of paragraph two, α/α diploid should read a/α diploid, and in the upper part of Fig. 5*a* and in the third line of the Discussion, $\alpha 1/\alpha 2$ should read $a1/\alpha 2$.

Where biotechnology companies find the key to life

Wavertree is an exciting new environment for high-tech business.

A landscaped park with ultra-modern buildings and land for customised factories. Rents start at £35 a week and qualifying companies can benefit from maximum tax-free grants. Scientific support and advanced research facilities are available from Liverpool University and Polytechnic. And Wavertree couldn't be better situated, with excellent road, rail, air and sea links.

wavertree technology park

So if you're in high-tech, why aren't you in Wavertree?

Ring Stanton Fuller on 051-228 2722 for more information.

Wavertree Technology Park, Dryden Road, Liverpool L7 9PG. Tel: 051-228 2722

PRACTICAL ASPECTS OF GAS CHROMATOGRAPHY/MASS SPECTROMETRY

by **G.M. Message**

This is a single-source reference describing how and why gas chromatography and mass spectrometry instruments work. The book describes a wide range of technologies and offers guidance for their optimum use, outlining good practice, routine procedures, and trouble shooting.

Contents: GC/MS SYSTEMS AND COMPONENTS: Vacuum Systems, Mass Spectrometers; Gas Chromatography; GC/MS Interfacing; Data Systems; ROUTINE GC/MS OPERATION, TECHNIQUES, AND PROCEDURES: Gas Chromatography Methods and Techniques Relevant to GC/MS; Mass Spectrometer Operation; Laboratory Practice; Preventive Maintenance; TROUBLESHOOTING FAULTS ON GC/MS SYSTEMS: The GC/MS Instrument Under Fault Conditions; Fault Finding and Nonroutine Maintenance; CHOOSING A GC/MS SYSTEM: Instrument Selection and Evaluation; Bibliography; Index.

POLYMERS:
The Origins and Growth of a Science

by **H. Morawetz,** *Polytechnic Institute of New York*

This historical introduction to polymer science integrates the important historical developments into the current context of the science. It covers early developments, natural and synthetic polymers, the development of synthetic rubber, physical principles, physical and spectroscopic methods, addition and condensation polymerization, molecular biology and polymers in solution.

0471 89638 1 | 324pp | April'85 | £54.95

ROOM TEMPERATURE PHOSPHORIMETRY FOR CHEMICAL ANALYSIS

by **T. Vo-Dinh,** *Oak Ridge National Laboratory*

A Guide to using room temperature phosphorimetry (RTP), a new approach in phosphorimetric analysis, covering this technique more thoroughly and explicitly than any other previous monograph. It is designed for anyone who wishes to apply RTP, or to extend it to various new analytical or physical studies.

Series: Chemical Analysis, Volume 68

0471 87884 7 | 324pp | May'84 | £57.85

ORGANIC ELECTRONIC SPECTRAL DATA, Volume XX — 1978

by **J.P. Phillips,** *University of Louisville,* **D. Bates,** *Michigan Tech University,* **H. Feuer,** *Purdue University* and **B.S. Thyagarajan,** *University of Texas*

This is the latest volume in the series and continues the cooperative effort to abstract and publish in formula order all the ultraviolet-visible spectra of organic compounds presented in the journal literature of the field. More than fifty chemists have searched over one hundred journals in the course of the project. Volume XX raises the number of spectra compiled to 450000, the largest ever assembled.

Series: Organic Electronic Spectral Data Series, Volume 20

APPRAISAL OF TESTS TO PREDICT THE ENVIRONMENTAL BEHAVIOUR OF CHEMICALS, SCOPE 25

edited by **P.J. Sheehan,** *Division of Biological Sciences, National Research Council of Canada,* **F. Korte** and **W. Klein,** *Gesellschaft fur Strahlen- und Umweltforschung, West Germany* and **P. Bourdeau,** *Commission of the European Communities, Belgium*

Predicting the fate of toxic chemicals in the environment is an important scientific task. This book appraises tests to predict the environmental behaviour of chemicals, giving expert evaluation of texting protocol. Methods and evaluations include descriptions of important transfer and transformation processes in air, soil and water. The quantification of key processes and reactions is described and appraised for accuracy, precision and utility and the limitations of specific laboratory and field techniques are discussed. Promising new methods are presented with recommendations for further research

Series: SCOPE Report Number 25

0471 90545 3 | 396pp | March'85 | £38.50

METHODS FOR ESTIMATING RISK OF CHEMICAL INJURY:
Human and Non-Human Biota and Ecosystems, SCOPE 26

edited by **V.B. Vouk, G.C. Butler, D.G. Hoel** and **D.B. Peakall**

Dealing first with the assessment of probable damage to the human organism, the book discusses the basic mechanisms of mutagenesis and carcinogenesis, the validity of long-term whole-animal studies as predictors of human response and the use of epidemiology, statistics and mathematical modelling in developing quantitative risk estimation. The same approach is adopted for non-human biota and ecosystems, including a state-of-the-art assessment of work in single-species tests, multispecies tests and ecotoxicological modelling.

0471 90546 1 | 720pp | May'85 | £57.00

POLLUTANTS AND THEIR ECOTOXICOLOGICAL SIGNIFICANCE

edited by **H.W. Nurnberg,** *Institute of Applied Physical Chemistry, Julich, Federal Republic of Germany*

Considers the major organic and inorganic chemical pollutants which have ecotoxicological significance in the atmospheric, aquatic, terrestrial and human environments. Major ecochemical aspects of the pollutants are covered with respect to their fate, behaviour, transfer and pathways as functions of the important general and specific parameters of the various types of ecosystem.

0471 90509 7 | 530pp | April'85 | £49.50

RECEPTOR MODELING IN ENVIRONMENTAL CHEMISTRY

by **P.K. Hopke,** *Institute for Environmental Studies, University of Illinois, Urbana-Champaign*

The first book that comprehensively reviews the rapidly growing field of receptor modeling. It systematically presents the analytical and mathematical methods that have been developed and used in source apportionment of airborne particulate matter. The book focuses on airborne, particulate matter since in this area, the methods have been extensively applied.

Series: Chemical Analysis Series, Volume 76

What's the matter?

Niles Eldredge

The Problems of Evolution. By Mark Ridley.
Oxford University Press: 1985. Pp.159. Hbk £12.50, $19.95; pbk £3.95, $8.95.

PROBLEMS in biology, in sharp distinction to those of philosophy, are solvable — or so writes Mark Ridley in the preface to *The Problems of Evolution*. Ridley has organized his book around a series of ten Great Problems currently (albeit, he says, timelessly) besetting evolutionary biology, problems that curiously decrease in their apparent solvability quotient as one ascends the scale of biological complexity and at the same time approaches the end of the book. Ridley's preoccupation with the answers to questions imparts an eerie quality to his narrative. On the one hand he is often quite sure of having *the* answer to a particular problem (for example the gene is the unit of selection), a sort of certainty I had thought was no longer fashionable in science in general (and particularly in the domain of evolutionary studies, justly known for its authoritative imaginary tales). On the other hand, I must admit to some frustration when Ridley throws up his hands and announces that a problem still defies solution, and that, in fact, our understanding remains at the same low level attained in earlier days. It seems to me that rather more progress has been made towards resolving some of the confusion in evolutionary biology than Ridley seems willing to concede.

Whence this collision between certitude and confusion? Ridley's book accurately reflects the generally unsettled state of evolutionary biology, for which, I think, David Hull is right to lay the blame on a pervasive "common sense" ontology that lies at the very core of the subject. Thus certitude stems from unexamined convictions on the very nature of such entities as genes, organisms, demes, species and taxa of higher categorical rank; and confusion ensues if we get our ontology wrong. Ridley's discussion of what species are — a stunning rerun of the Dobzhansky-Mayr position enunciated nearly 50 years ago — forms the crucial case in point. In this view, species are seen to be simultaneously reproductive communities and fairly coherent groupings of similar organisms, recognizably distinct from other such groups. Ridley is thus forced to repeat the standard claim that species are "real" at any one time (especially well demarcated in sympatry with close relatives), but through time will, of necessity, disappear, evolving themselves out of existence as they transform into descendants. Species exist only in a single time plane, according to this view, a conceptualization that understandably outraged George Gaylord Simpson.

In this received ontology, species are real, individual entities when construed as reproductive communities at any one time; they are also classes of similar organisms. Moreover, the economic adaptations of organisms (the main source of that similarity) are imagined to be in a constant state of overhaul, and so the properties of the members of the class change, and a species evolves itself out of existence. Ridley simply does not report that Ghiselin and Hull over a decade ago pointed out that "things" are either classes or individuals, and that there is no real trick to seeing species, if construed as reproductive communities, as individuals in time as well as in space. Species emerge as spatiotemporally bounded historical entities, regardless of how much, or little, adaptive modification may accrue in the phenotypes of their component organisms. Much of the doubt and confusion permeating the second half of this book stems directly from Ridley's certitude over the basic nature of species, based as it is on a rather garbled ontology.

Indeed, overall the book is an excellent statement of mainstream evolutionary biology as it stands today. If it does not expose the *real* problem in evolutionary theory — the ontological issues — it does paint an accurate picture of the teleological-ridden "who or what benefits" approach that selectionists seem ever more locked into as a source of explanation for all manner of biological phenomena. Nor is Ridley utterly conventional. Within the overall matrix of neo-Darwinian theory, he follows the Williams–Dawkins reductionism that sees the gene as the locus of evolutionary action. And, in an amusing and effective gambit that coincides well with my own prejudices, Ridley discusses systematics by contrasting phenetics and cladistics, claiming the latter is evolutionary and the former not, thereby allowing him to brush aside the vast middle ground of "evolutionary systematics" as an uninteresting muddle of the two extremes. Moreover, while Ridley is clear that cladistics does not depend upon any prior theory of how evolution actually works, in several places he makes a link between nested patterns of resemblance linking up all elements of the biota and the simple notion of descent with modification. Those nested patterns of similarity have always been the strongest evidence that life must have had an evolutionary history, and it is refreshing to see it acknowledged once again, just as a journalist in the United States, in a feat of literary legerdemain, has recently tried to show how cladistics somehow throws doubt on the very idea of evolution.

Ridley's book is not a "fun" read. Indeed, it is difficult to determine to whom it is addressed. The style, superficially zesty ("And the prediction is this .... Here is the final result"), is actually rather flat and utterly matter-of-fact: there seems for Ridley no *joy* in these rather marvellous mysteries. The level is decidedly elementary — as if the intended audience were beginning students or the ever-elusive "intelligent layman" — yet the tone is so unrelentingly serious and the pace so brisk that all but the most dedicated will surely flag.

Perhaps most importantly, however, the book does not get at what I think is *really* the matter with evolutionary theory. But as a quick yet pretty accurate summary of most of the current topics under debate, and as a source of insight about how most evolutionists still approach their topic, it should prove useful indeed. □

Niles Eldredge is at the American Museum of Natural History, New York.

New journals review

On 26 September *Nature* will publish the fifth annual review supplement devoted to science journals.

Criteria for inclusion of a journal in the 1985 issue are that:

(i) the first number appeared, or the journal was retitled, *between June 1983 and May 1984* (the second cut-off date allows at least three issues of a journal to have been published, the minimum number on which a reasonable judgement can be based);

(ii) it is published at least three times a year;

(iii) the main language used is English.

Publishers and learned societies are invited to send *four different issues of each suitable periodical, including the first and most recent numbers* (if from outside the United Kingdom, by air mail) to: The Review Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF, England. Subscription details for both 1985 and 1986 should be included.

Home in hyperspace

Deborah Singmaster

The Fourth Dimension and How to Get There. *
By Rudy Rucker.
Rider-Hutchinson: 1985. Pp.228. £9.95.

THE dust jacket of the British edition of Rudy Rucker's *The Fourth Dimension* carries a picture that looks like a shot from the final sequence of *Star Wars*. It could be a post card from the fourth dimension, and if it were from the author it would say "Wish you were here!". Rucker admits that he is in love with cosmology and in this exhilarating book he tries to convey his enthusiasm to his readers.

The book is dedicated to "A Square, on his hundredth anniversary" — an apt tribute to another book on the same theme, *Flatland* by the English school master Edwin A. Abbott, published in 1884 and gallantly kept in print in Britain by Basil Blackwell. It deserves to be more widely read than it is. Rucker makes frequent references to *Flatland* throughout his book; he has even written a sequel to the original.

Starting with Plato and the allegory of the shadows on the wall of the cave, Rucker moves by analogy towards a description of a spatial fourth dimension. He introduces the hypercube, "probably the best-known 4-D geometrical problem", and proceeds to the hypersphere, hyperspace tunnels, the shape of space, spacetime and so on. From these literal interpretations of a fourth dimension, he passes to more abstract uses of the term and suggests that we, with our complex interior world of thoughts, feelings, dreams, are "in some very real sense, beings of more than three dimensions".

Rucker has no difficulty in thinking four dimensionally. He quotes Charles Hinton, "the great hyperspace philosopher" and a contemporary of Abbott's, as saying that one of the best methods of preparing oneself for four-dimensional thought is to create a deliberate confusion between left and right, by experimenting with mirror images, for example. One of the most entertaining of the many anecdotes in the book is Rucker's potted biography of Hinton, the son of James Hinton who advocated and practised free love. Charles, who was himself convicted of bigamy, believed that "space is, at the deepest level, to be known by the heart and not the brain". But that way mysticism lies: Rucker is at times unashamedly mystical.

For mathematical greenhorns, Rucker provides simple explanations of major concepts including Einstein's theory of relativity, quantum mechanics and David Hilbert's theory of infinite dimensional spaces. He also discusses less orthodox notions such as synchronicity and the possibility of time travel — he is, after all, apart from being a mathematical logician, a writer of science fiction.

Appropriately, *The Fourth Dimension* is a fourfold book. Besides the text there are witty and helpful diagrams and illustrations by David Povilaitis, the margins contain extensive quotations from writers as diverse as Plato, Ouspensky, Lewis Carroll and Borges, and there are also puzzles for those whom Martin Gardner, in his foreword, describes as "the mathematically competent". (Answers are supplied.)

Rucker's book is not aimed at the trained mathematician or physicist but it should appeal to anyone else who is interested in the nature of the Universe and our part in it. Science undergraduates, even sixth formers, and all science fiction enthusiasts will find it (and *Flatland*) stimulating reading. This is a refreshing and thought-provoking book written by an engaging optimist for whom, unlike Pascal, infinity holds no fears. □

Deborah Singmaster is a freelance writer and broadcaster.

* In the United States *The Fourth Dimension: Toward A Geometry of Higher Reality*, published by Houghton Mifflin. A technical review of the book appeared in *Nature* **312**, 214 (1984).

Distant reactions

Alexander Dalgarno

Interstellar Chemistry.
By W.W. Duley and D.A. Williams.
Academic:1984. Pp.251. $45, £29.

THE discovery in the dense regions of interstellar space of molecules, ranging in complexity from simple diatomic species to extended linear chain polyynes, has provided a unique diagnostic probe into the physical conditions in which star formation occurs. Analysis of the intensities of molecular emission and absorption lines yields estimates of the densities, temperatures, velocities and radiation characteristics of the environment; observations of absorption by rotational levels of the diatomic cyanogen molecule CN have given us a measure of the temperature of the blackbody radiation of the Universe at wavelengths of 2.6mm and 1.3mm; and observations of emission from deuterated molecules have yielded a value for the density of matter in the early Universe, showing that baryonic matter cannot close the Universe.

Molecules are found also in the material ejected by protostellar objects as they begin their evolution to the main sequence, and in the circumstellar shells and stellar winds of massive stars which undergo mass loss throughout their existence. Molecular masers are clear signposts marking phases in the sequence of events that leads to the formation of stars and the dissipation of the remnant material out of which they are made. Vibrationally excited molecular hydrogen is widely observed and provides insight into a diverse range of phenomena, among them galaxies in collision.

Molecules are much more than probes of exotic environments, however; they are also highly effective cooling agents. Molecular emissions carry away thermal energy and bring molecular clouds to the brink of gravitational collapse. Molecules play a controlling role in the ionization balance of collapsing objects and in the dissipation of rotational angular momentum by magnetic braking.

To utilize fully molecular observations in the investigation of astronomical phenomena we must understand the nature of the processes by which molecules are formed and destroyed. Those processes belong to a special kind of chemistry, a chemistry that is now an integral part of astronomy and that is the subject of Duley and Williams's book.

Interstellar chemistry is a combination of gas phase chemistry and surface chemistry. The phenomena under study occur at densities too low for the three-body processes that control terrestrial gas phase chemistry, and the formation of molecular compounds is initiated by radiative associations in which the reactions are stabilized by the emission of photons. The temperatures can be as low as 5K, though in localized regions the passage of a shock heats the gas to several thousand degrees and may dissociate the molecules which then form into new compounds as the heated gas cools and the atoms recombine. The interstellar medium contains grains, refractory particles of dimensions of the order of 10^{-5}cm, on whose surfaces molecules may form to be later released into the gas phase. The gas phase and surface reactions take place together in a medium bombarded by energetic cosmic rays and subjected to X-rays and to ultraviolet photons from embedded stars and exploding supernovae.

Thus a diverse array of basic chemical processes forms the content of interstellar chemistry. Duley and Williams have written a lucid account of these processes in a book in which the background is developed sufficiently to make apparent the relevance of chemistry to astronomy. Here the two disciplines are woven together in a pattern of absorbing interest which should appeal to a broad range of scientists. A limited familiarity with elementary molecular physics is adequate preparation, but at the same time the authoritative tone reflects the fact that both authors are active researchers in this field. Their book will come to be seen as the standard introduction to the subject. □

Alexander Dalgarno is Phillips Professor of Astronomy at Harvard University.

Bone, bones and biomechanics

Charles E. Oxnard

The Mechanical Adaptations of Bones.
By John Currey.
Princeton University Press: 1984. Pp.294. $37.50, £37.20.

FOR earlier generations, D'Arcy Thompson's *On Growth and Form* (published in 1917) and P.D.F. Murray's *Bones* (1934) provided the critical descriptions of what was then known about biomechanics and the mechanical adaption of bone. Nearer our own time, F. Gaynor Evans's *Stress and Strain in Bone* (1957) both provided a summary of the exciting if somewhat confused earlier investigations and marked the beginning of new research based upon the insights of modern engineering. John Currey's book is the natural current successor, together with McNeill Alexander's 1968 and 1984 editions of *Animal Mechanics*, and Wainright, Biggs, Currey and Gosline's *Mechanical Design in Organisms* (1976). Each of these books supplies its own commentary on the general subject, but, although there is inevitably some overlap, they concentrate upon different facets of the field and are aimed at different readerships.

Much of the early work, often dating from the last century and important though it is, confused stress, strain and architecture; the new investigations described by Currey do not. The old studies followed engineering strength-of-materials traditions by presenting biological materials, especially bone, as though they were homogeneous, isotropic and perfectly elastic bodies capable of being described through infinite beam theory. Currey discusses the new approaches which acknowledge that, like many non-organic materials, bone is inhomogeneous, non-isotropic and demonstrates imperfectly elastic, poroelastic and plastic-elastic properties, and each at several different microscopic levels. In particular, these approaches imply that stress in bones, especially irregular bones and the odd-shaped ends of long bones, is better characterized through techniques such as finite element analysis.

Currey recognizes that all bone and all bones are not alike, and gives many examples of how different types of bone and different designs of bones serve differing functions. He discusses, for instance, differences in form and physical properties of bone ranging from the brittleness and stiffness of the auditory elements in whales related to the transmission of sound in water to the curvatures of finger bones used to suspend the bodies of brachiating apes from branches.

In contrast to many other writings on this subject, Currey also describes not only immediate and ontogenetic bony adaptation, but takes into account the evolutionary perspective. He makes a convincing case for the design of bone by natural selection while recognizing phylogenetic constraints; and he considers the all-pervasive action of natural selection in producing optimum structure while emphasizing that all mechanical properties of biological materials are a compromise between conflicting requirements.

Perhaps most importantly of all, however, in this book Currey provides an introduction for biologists to the basic ideas of strength of materials and mechanics. This is a summary that should do much to remove misconceptions that still remain in the minds of some students and even some investigators in this area. Among them are the idea that if one set of stress trajectories is compressive then the other must be tensile (which does not necessarily follow), that a limb under tension implies bone under tension (which it need not) and that mechanical stresses are chiefly borne by bone (they are not: the little known interior complexity of the muscle–tendon unit, and those even less understood and poorly described elements, fascial sheets and ligaments, are all important stress-bearing features especially in the larger land animals).

Finally, although Currey's book unhesitatingly simplifies the ideas of strength of materials in order to aid student understanding, it also reminds us, at almost every step, that real biological situations are much more complex; therein lies the future of these studies. The book is, thus, an excellent source of facts and ideas for students and a resource for their teachers, while at the same time providing a superb set of problems for investigators. □

Charles E. Oxnard is University Professor and Professor of Anatomy and Biology at the University of Southern California. He is author of The Order of Man *(Yale University Press, 1984).*

Light on polymers

Herbert Morawetz

Polymer Photophysics and Photochemistry: An Introduction to the Study of Photoprocesses in Macromolecules.
By James Guillet.
Cambridge University Press: 1985. Pp.391. £45, $79 50.

IN these days of extreme specialization, it is rare to find an author who is equally at home in photophysics and photochemistry. Thirty years ago James Guillet worked under Norrish's direction on a doctoral thesis dealing with the photodegradation of polymeric ketones. Since then, he has not only continued to be a leader in polymer photochemistry, but has made seminal contributions to the study of fluorescence and phosphorescence of polymers, both in solution and in bulk, and has published stimulating accounts of the "antenna effect" in which the energy absorbed by a small number of chromophores is relayed along a polymer chain to excite a group far removed from the absorption site. While Professor Guillet's hope that such a process would lead to a chemical reaction has not been realized so far, it is an exciting possibility which may well be demonstrated in the future.

Although areas in which Professor Guillet has been active are stressed more heavily in this his latest book, it does contain an excellent coverage of the field. The only major area I missed is the extensive Russian contribution to the study of polymers by emission anisotropy, which has been summarized by Anufrieva and Gotlib (*Adv. Polym. Sci.* 40, 1, 1981). The effect of the adsorption of fluorescent dyes on their emission characteristics might also have been mentioned.

While the book is an outstanding introduction to photophysics and photochemistry for polymer scientists, I am less sure that the discussion of the principles of polymer science will be adequate for those unfamiliar with this field. There are a number of errors: the expansion coefficient α (p.33) is not treated as chain length dependent; rotational isomeric state calculations (p.34) depend little on the height of rotational barriers; there are no D and L configurations in stereoregular vinyl polymers; the lamellar thickness of folded polymer chains (p.46) is of the order of 10 nm not 1000 nm; it is not possible to estimate the intrinsic viscosity from measurements at a single concentration without knowledge of the "Huggins constant" (p.74); the spacing of phenyl groups in the helix of isotactic polystyrene is not "of the order of 3Å" but much too large for excimer formation (p.178); and Haas *et al.* and Sisido (p.230) did not study cyclization. It is also a pity that the references only run up to 1981. But these are minor blemishes on a most useful book which is a valuable addition to the polymer literature. □

Herbert Morawetz is a Professor in the Department of Chemistry at the Polytechnic Institute of New York.

New in paperback

- A single-volume edition of Christian de Duve's *A Guided Tour of the Living Cell.* Publisher is W H. Freeman, price is $33 95, £24.95 Sterling price of the hardback is £35.90 per two-volume set, not £39.90 as printed in the review (*Nature* 314, 694; 1985)

Scattering sources

R.A. Cowley

Theory of Neutron Scattering from Condensed Matter, Vols 1 and 2.
By Stephen W. Lovesey.
Clarendon: 1984. Vol. 1 pp.329. Vol. 2 pp.344. £38, $59 each volume.

NEUTRON scattering now plays an essential role in our understanding of many properties of condensed matter, and is used in the study of atomic structures, interatomic forces, magnetism, liquids and polymers. Stephen Lovesey has made significant contributions on the theoretical side of the subject. With Walter Marshall, in 1971 he published *Theory of Thermal Neutron Scattering*, which has been an essential reference book for neutron scatterers, particularly in the field of magnetism, and which was influential in the development of the use of correlation functions for describing the scattering.

The present two volumes extend the coverage of the field beyond that of the earlier book; Vol. 1 describes elastic nuclear scattering, scattering by lattice vibrations and by liquids, and some chemical applications, while Vol. 2 deals with elastic and inelastic magnetic scattering. Although the second volume is entirely rewritten, most of its contents and the manner of treatment will be familiar to readers of *Theory of Thermal Neutron Scattering*.

In neutron scattering, the Van Hove correlation function is a natural bridge between experiment and theory. The task of the experimentalist is frequently to perform measurements of the function which can then be interpreted in terms of a model for the particular system. Unfortunately there is very little in either of the books about the theory of how to obtain it from measurements of the scattered intensity. There is also nothing on the theory of the experimental resolution or other experimental constraints. The books are a helpful source for the calculation of the Van Hove function for a wide variety of soluble or nearly soluble models, and although I found them difficult to read they will undoubtedly prove valuable for detailed derivations of particular models. It is, however, a pity that the importance of the formulae produced are not illustrated through more examples of experimental results and discussion of when the simple models apply or do not apply to real systems.

Stephen Lovesey has again provided us with a very useful work of reference. These two volumes should not be used as textbooks because of the neglect of experimental aspects of the subject and of applications to real systems. The books, however, will be consulted by neutron scatterers for many years. □

R.A. Cowley is Professor of Physics at the University of Edinburgh.

Masters of swing

Russell H. Tuttle

The Lesser Apes: Evolutionary and Behavioural Biology.
Edited by Holger Preuschoft *et al.*
Edinburgh University Press/Columbia University Press: 1984. Pp.709. £65, $56.

DESPITE their modest size and colloquial label, the lesser apes (Hylobatidae) can claim a fair share of superlatives. They are the most numerous and variegated, relatively longest limbed, "swingingest", most naturally bipedal, most musical and most socially cohesive of the apes. We do not know whence they came or how they acquired their remarkable adaptive complexes; but few scientists would deny that we are blessed to have them grace the Earth.

Preuschoft and his colleagues have paid them just homage in this well-produced, fact-packed volume, which presents the augmented results of a conference held near Ulm, West Germany, in 1980. It will be a long-lasting source book on *Hylobates*. The organization of the work reflects its major purpose, that is to impress the world with the need to conserve forest habitats and thereby preserve the glorious gibbons of south-eastern Asia. Hence the first of the five sections is devoted to conservation. Its authors are soberly persuasive.

The plights of Javan silvery gibbons, Mentawai Kloss gibbons, South Asian hoolocks, Thai pileated gibbons and Chinese concolor gibbons are particularly acute. Our knowledge about the effects of high-technology warfare on wildlife in Kampuchea, Laos and Vietnam ranges from scanty to nil, but if the destruction of human life is any index the hylobatids probably have only a poor chance of long-term survival there.

It is now virtually certain that monogamy and territoriality are universal among the Hylobatidae, though we cannot yet tell whether new groups are formed by the same mechanisms or whether defence of a section of the range serves comparable adaptive functions in all species. All of them call dramatically (and beautifully) but there is notable interspecific variation in which of the sexes calls, displays athletically, and chases and attacks in reaction to the calls of neighbours, actual intrusions or other factors. The interplay between calling, monogamy, subsistence and territorial defence in *Hylobates* has proved an attractive problem for a host of biologists, and Sections 3 and 4 of *The Lesser Apes* contain a wealth of information on the topic. Given their relevance to salient problems in theoretical biology, anthropologists can no longer be viewed as the proprietors of the hylobatid apes.

Functional morphologists have made great strides in elucidating the mechanisms underpinning hylobatid brachiation (arm-swinging), bipedalism and vertical climbing. As with conservation and ecological and behavioural puzzles, the lesser apes have ecumenically challenged Asian, European and North American anatomists and kinesiologists to explain their peculiar positional behaviour. Section 2 of the book is an excellent report of results from modern, technically and mathematically sophisticated, studies on hylobatid subjects and specimens. Here we learn that because of their elongated forelimbs, the movements of slowly brachiating hylobatids correspond reasonably well with the model of a mathematical pendulum, and that the elongation of the forelimbs economizes energy during rapid (ricochetal) arm-swinging.

It is heartening to see a reiteration (on pp. 94–95) of my 1975 model for the stem hominoids as hylobatid-sized, versatile arboreal beasts that were not especially adapted for dramatic brachiation. But I would have been happier had Herr Hollihn cited Tuttle among the long list of references that inspired him to adopt it. □

Russell H. Tuttle is Professor of Anthropology at the University of Chicago.

New Volumes from

Handbook of Experimental Pharmacology

Volume 76

Clinical Pharmacology of Antianginal Drugs

Editor U. Abshagen

1985 81 figures XVI, 552 pages Hard cover DM 460,- ISBN 3-540-13110-8

This volume reviews the epidemiology, pathophysiology and especially the treatment of coronary heart disease Introductory chapters on epidemiology and pathophysiology are followed by a methodical section in which all presently used, relevant methods of assessing pharmacological or therapeutic activity of antianginals are discussed with respect to experimental animals as well as to normal and diseased humans This gives those not actively working in the field a solid foundation for critically reading and better understanding the succeeding chapters The emphasis placed on clinical pharmacology and research is of immediate relevance for therapeutics Thus, the volume provides not only the pharmacological basis for treatment, but also the scientific principles of therapy itself and the rational methods for its assessment

Volume 75

Toxicology of Inhaled Materials

General Principles of Inhalation Toxicology
Editors **H.P. Witschi, J.D. Brain**

1985 80 figures XVII, 553 pages Hard cover DM 490,- ISBN 3-540-13109-4

The book addresses the methods and scientific basis of inhalation toxicology The particular scope of this volume provides an overview of the modern and appropriate methodology and current state-of-the-art in inhalation studies Methods covered include the design and operation of inhalation chambers, choice of animal species, and techniques designed to evaluate quantitatively the morphologic and biochemical changes brought about in the lung by toxic inhaled materials Considerable emphasis is given to morphologic and biochemical techniques This book, written by experts in the field, provides information on the development and use of techniques in one single, compact volume

Volume 74

Antiepileptic Drugs

Editors **H.-H. Frey, D. Janz**

1985 54 figures XXII, 867 pages Hard cover DM 680,- ISBN 3-540-13108-6

This volume provides a comprehensive and critical survey of our present knowledge of the experimental and clinical pharmacology of antiepileptic drugs Its thorough review of the experimental literature makes it invaluable for both academic and industrial researchers in the field. It includes sections on epileptic diseases in man and animals as well as on pathophysiological mechanisms active in these diseases which may provide starting points for the development of new antiepileptic drugs

Volume 73

Radiocontrast Agents

Editor **M. Sovak**

1984 189 figures XVI, 609 pages Hard cover DM 490,- ISBN 3-540-13107-8

The purpose of this book is to summarize recent developments in the field of contrast media design, synthesis and pharmacology and to stimulate further research in the area To this end the book contains a review of methodology applicable to contrast media research There is no concise text summarizing developmental and experimental aspects of contrast materials In that sense, this book is unique

... a splendid achievement."
—Nature

Honorable Mention in the 1984 American Medical Writers Association Awards

HISTOLOGY:

Cell and Tissue Biology, *Fifth Edition*

Edited By Leon Weiss, M.D.

Grace Lansing Lambert Professor of Cell Biology
Department of Animal Biology
University of Pennsylvania

This extensively revised and updated fifth edition of ***Histology: Cell and Tissue Biology*** uses the latest technological advances in histology to bring a complete, coherent survey of all aspects of mammalian tissue culture to the classroom.

Histology, Fifth Edition is the ideal teaching resource. Its self-contained chapters, each written by an expert in the field, allow the professor to form an individualized curriculum through selective readings. In addition, students will appreciate the detailed outlines preceding every chapter and the careful explanations of all new terminology. The 1206 illustrations, including color plates and photomicrographs, eliminate the need for a supplementary atlas.

Because this text emphasizes the relationship between morphology and function, it is the definitive work for today's medical, dental, and veterinary curricula. ***Histology, Fifth Edition,*** is the text of choice for many upper-level undergraduate courses in basic biomedical sciences as well as a long-term reference for board exams and further studies in physiology, pathology, and pharmacology.

From reviews of the fifth edition:

"This very comprehensive book is, as indicated by its subtitle, much more than a textbook of histology . . . lucidly written and well illustrated . . . an excellent book."
The Lancet

"It is one of the three great books on histology written in English . . . the new Weiss is a splendid achievement."

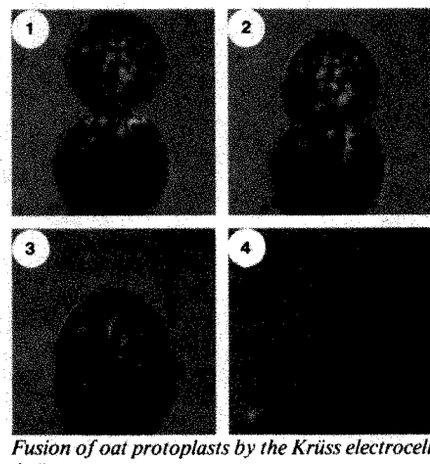
Achema bigger than ever

The Achema-85 exhibition takes place in Frankfurt on 9–15 June. Halls 6-I, -II and -III cover laboratory and analytical techniques, Hall 2 research and innovation.

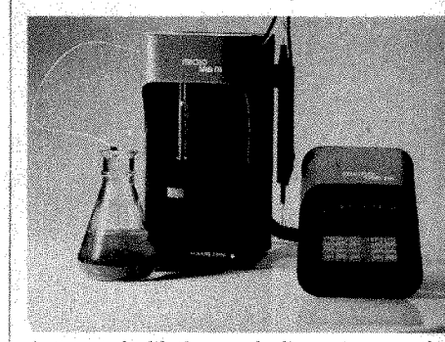


● The theme of Mettler's exhibit at Achema is laboratory efficiency. Mettler is showing a selection of electronic analytical and precision balances, as well as various systems that can be realized with balances or instruments. Of particular note is a compounding system for chemical or pharmaceutical companies where a number of balances are connected directly to a single computer which controls and monitors the balances. Another system demonstrates the use of lab robots with balances and instruments. Also on view are automatic systems for titration and thermal analysis — the DL40RC MemoTitrator, the DL20 CompactTitrator for routine analyses, and the DL18 Karl-Fischer titrator. The TA3000 thermal analysis system is now equipped with a graphic video screen, and many visitors will also be interested in the RC1 reaction calorimeter which measures the heat flow of chemical reactions and physical transformations.
Stands FG5-9, Hall 6-III & AB2-3, Hall 5
Reader Service No. 100.

Bioculture control by Applikon.

● The Applikon Bio-Processor ADI 1020 is an advanced and flexible system for total fermentation control. The system is dedicated to control various parameters during the growth of a bioculture, comprising three control levels. Levels 1 and 2 take care of the measurements, controls and data transmission and level 3 is for data handling. The modular build up of levels 1 and 2 allows the system to be tailored to virtually any biological process. At level 3 there is the option either to use the ADI dedicated and preprogrammed unit, including video and keyboard, or the ADI RS 232 interface to connect to a personal computer.
Reader Service No. 101.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

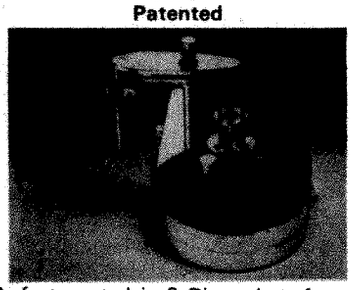


Fusion of oat protoplasts by the Krüss electrocell fusion process.

● Krüss GmbH, of Hamburg, makers of equipment to measure surface tension, has moved into genetic engineering with the introduction of the CFA 400 system for electrically induced cell fusion. The latest development from Krüss is an electroporator making it possible to load biological cells with genetic material. In this method, brief electric pulses induce the reversible breakdown of the cell membrane, the cells are "perforated" for a short time without losing viability. Cells (up to 1 ml) are pipetted into a sterile chamber, mixed with the DNA and exposed to a sequence of electric pulses. The DNA is then taken up by the cells. Subsequently the cells are selected for the desired criteria. During electroporation the cells can be observed under a microscope. As well as DNA, other substances, including drugs, may be loaded in cells in this way, with possible implications for specific therapy. The equipment is controlled by a microprocessor and thus easy to operate. Visitors to the Krüss stand will be able to view the fusion of erythrocytes under the microscope on a video system connected to it.
Stand E-19, Hall 6-I
Reader Service No. 102.

● May & Baker Laboratory Products will be introducing a number of products onto the German market at Achema. On view will be the May & Baker range of HPLC solvents, which includes many solvents that are not available elsewhere. The Pronalys AR range of analytical reagents, Intafaze phase transfer catalysts and Volucon standard concentrates will also be displayed. The Intafaze range includes TDA-1, the first universal crown ether to be made commercially available. TDA-1 is capable of catalysing a wide variety of reactions that would otherwise need expensive solvents.
Stand E22, Hall 6
Reader Service No. 103.

● The Asypor range of membrane liquid filters recently introduced by Domnick Hunter Filters Ltd is claimed to give double the flow rates and double the throughputs achieved with conventional membranes. The Asypor membrane has a unique asymmetrical pore structure. The pore size on the upstream surface is larger than on the downstream surface by a factor of 5 : 1 for optimum performance. Asypor cartridges are available in a range of rated pore sizes from 0.2 to 3 μm with a full range of end cap styles for retrofitting into existing filter housings. The Asypor membrane is also offered in a selection of disks in the standard diameters for process and analytical applications. Asypor disks and cartridges meet FDA requirements and conform to USPXX Class VI. They are integrity testable and have low extractables.
Reader Service No. 104.



Automated dilution and dispensing — the Hamilton Microlab.

● The new Hamilton Microlab M diluter/dispenser should find application wherever precise liquid handling is required for volumes between 1 μl and 25.5 ml. For instance, for sample distribution, dilution series or in the preparation of samples for further processing in different analytical instruments. The Microlab M can also be linked with a balance and a computer for the automatic preparation of standard solutions. Software packages are already available for various balances. The instrument can be controlled by any computer via an RS 232 C interface. Dialogue with the dispensing unit is conducted in ASCII code via the serial data circuit. The Microlab M is programmed via the controller keyboard (up to 587 program steps, maximum storage capacity 99 methods). The stored methods can be viewed ("roll" function) or printed out. Syringe volume, aspirating and dispensing speeds can now be stored, with aspirating and dispensing speeds individually programmable between 1 and 99 seconds.

LIPOSOMES NEW!
reproducible — homogeneous — extremely rapid —

The new commercial **LIPOSOMAT®** provides reproducible preparation of uniformly sized unilamellar liposomes (formation within 10 minutes) with very high encapsulation efficiency for both hydrophilic and/or lipophilic agents. Liposome size selectable between 25 and 60mm diameter. Lipid loss far below 1%.

Sample volume normally 5-10 ml or up to 200 ml if used in combination with an additional apparatus.

The LIPOSOMAT® is used especially for studying drug/protein/cell — liposome interactions in vitro and in vivo, for reconstitution experiments, and for the transfer of genetic material in gene and biotechnology.

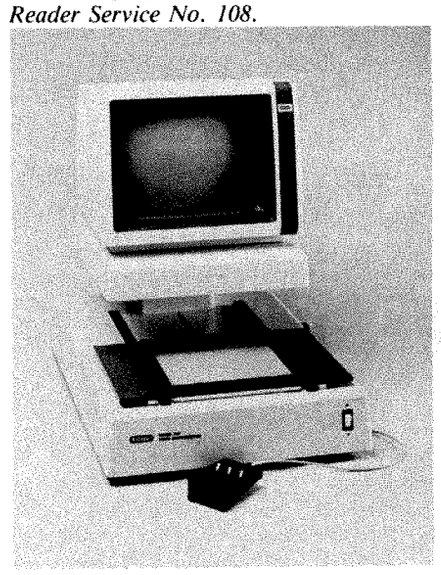
Call toll-free 800-521-3044. In Michigan, Alaska and Hawaii call collect 313-761-4700. Or mail inquiry to: University Microfilms International, 300 North Zeeb Road, Ann Arbor, MI 48106.

Schleicher & Schuell's membrane filters and filter holders.

● With the new membrane filters made from Nylon 66, the range of raw materials used in Schleicher & Schuell's membrane filters now includes cellulose nitrate, cellulose acetate, mixed cellulose esters, pure (regenerated) cellulose, as well as polyamide and PTFE. The Nylon 66 membrane filters, suitable for autoclave sterilization, are supplied as circles in diameters from 13 mm up to 293 mm and in pore sizes 0.2 and 0.45 μm. Nytran membranes are positively charged Nylon 66 membranes for the immobilization of nucleic acids and proteins. They interact with negatively charged biopolymers which become selectively bound and immobilized on the membrane. Because of its high binding capacity and good wet strength, Nytran is an excellent medium for electrophoretic transfer methods in molecular biology. Also on the Schleicher & Schuell stand is an extensive range of products for nucleic acid and protein research, including a number developed during the past two years, such as: DEAE and CM membranes for ionic immobilization, the Minifold II filtration manifold, a further development of the Dot-Blot process (Minifold I), the Quick-Blot kit for the selective immobilization of mRNA and Elutip-d, the mini-column which both purifies and concentrates dsDNA.

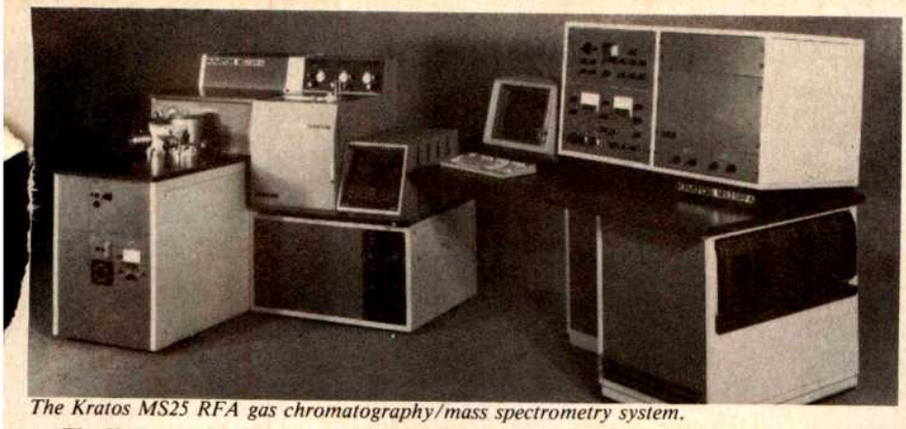


Stand DE3-4, Hall 6.
Reader Service No. 106.

● At Achema Elga Ltd, designers and manufacturers of water purification equipment, will be exhibiting a comprehensive range of laboratory and reverse osmosis products. Of particular interest to those involved in HPLC, atomic absorption or tissue culture, will be the updated Elgastat Spectrum RO unit. This system combines the technologies of reverse osmosis, deionization, media and membrane filtration to produce economical reagent grade water which meets all international standards. Elga will also be launching a completely new product for the production of ultra-pure water for use in medical and research laboratories.

Stand E13, Hall 6-II
Reader Service No. 107.

● Boehringer-Mannheim has introduced a new beta-galactosidase substrate, resorufin-beta-D-galactosidase, which has many advantages as substrate in biological systems. The aqueous solution is yellow (λ_{max} 470 nm). The cleavage product after enzymatic hydrolysis is red-violet (λ_{max} 570 nm), and possesses a light-red fluorescence (λ_{max} 583 nm) at *p*H values higher than 7. The inhibitor programme of Boehringer-Mannheim has been extended with the addition of the protease inhibitors E64 (for thiol proteases), phosphoramidone (for thermolysin), bestatin (for most of the exopeptidases), TLCK (for trypsin) and TPCK (for chymotrypsin), and the new alpha-glucosidase inhibitor bromoconduritol AB. Finally, Boehringer has launched new biochemicals for membrane research. To complement *N*-octylglucoside and *N*-dodecyl-beta-D-maltoside, the new introductions are CHAPS and the peroxide-free tensides Triton X-100, Thesit and isotridecylpolyethylene-glycol ether.



Reader Service No. 108.

The Bio-Rad Model 620 video densitometer.

● A number of new instruments will be making their debuts on the Bio-Rad stand. Amongst these are a totally digital video densitometer that provides electronic scanning and instant display of data; a portable HPLC analyser designed specifically for on-the-spot applications; a new HPLC MAPS system for the large-scale purification of monoclonal antibodies and a new moderately priced Digilab Fourier transform infrared spectrometer that provides true research-grade performance. Versatile yet simple to use, the Model 620 video densitometer allows the operator to process, optimize, evaluate and view data on a screen before it is printed onto a chart recorder. All operational procedures are selected from a menu displayed on the screen using a mouse-controlled cursor — there is no keyboard. Up to 30 lanes of data can be displayed and printed, and, if required, the operator can arrange these in a number of different formats.

Stand 19-21, Hall 6-III
Reader Service No. 109.

The Kratos MS25 RFA gas chromatography/mass spectrometry system.

● The Kratos Analytical stand features a complete range of liquid chromatography systems, the new MS 25 RFA GC/MS system (also available as an LC/MS), and a series of components for surface analysis. Shown for the first time in Europe is the Spectroflow 950 programmable fluorescence LC detector, which has full microprocessor control of all instrument functions from a touch-sensitive front panel, RS-232 serial interface, or contact closures. DS 650, a chromatography data system with SmartKey control introduced at the Pittsburg Conference, is also on show, together with a range of gradient formers, UV-Vis detectors, post-column reaction systems and pumps. The MS 25 RFA, another instrument on show for the first time in Europe, incorporates inhomogeneous field magnet technology to provide high mass range and ultra-fast scan speeds without loss of spectrometer resolution or sensitivity. An integral DS90 acquisition and processing computer controls the system in conjunction with the spectrometer's "Autoconsole" and distributed microprocessors.

Stand HJ15-16, Hall 6-III
Reader Service No. 110.

● Rheometrics, manufacturer of high technology instruments for material evaluation, has introduced the Rheometrics dynamic analyser (RDA-700). This versatile analytical instrument measures the viscoelastic behaviour of a broad range of materials (including thermoplastics, thermosets, structural composites, rubber, foods, and adhesives) by determining the sample's response to a sinusoidal shearing action. Since the RDA-700 is easy to use and is sensitive to subtle changes in resins and additives, it is ideal for research projects as well as production control. The RDA-700 is a forced frequency instrument rather than a resonant frequency one. This enables the operator to separate the effects of rate and temperature on material properties, making the instrument a sensitive indicator of molecular structure. Rheometrics manufactures a complete line of rheological and impact testing instrumentation for research and development, design, quality control, and process control.

Stand A8, Hall 9-I
Reader Service No. 111.

● The new range of remote-controlled magnetic stirrers from Dr Hoiss + Partner GmbH can be placed under vessels for normal use but can also be used as submersible magnetic stirrers in fluid baths. One possible application would be in sealed or temperature-controlled chambers, where it is advantageous to control the stirring process externally, without opening the chambers. The magnetic stirrers operate most efficiently when they synchronously stir many vessels in the many stirring positions. Different control units are available, suitable for different kinds of stirring tasks; a small, handy plug-in power supply unit or a bench-top unit. Other features include a start-key which simultaneously centres all the stir-bars on the stirring positions, so that it is possible to freely select stir and pause intervals. Following each pause, the stir-bars are re-centred, and the stirring direction reverses. In addition, it is possible to choose the stirring power and thereby facilitate temperature control in closed systems. The compact magnetic drives are available in two models — a 15-position model to simultaneously stir 15 beakers of 250 ml each, or a model for 6 × 1,000 ml Erlenmeyer flasks.

Stand J13, Hall 6-II.
Reader Service No. 112.

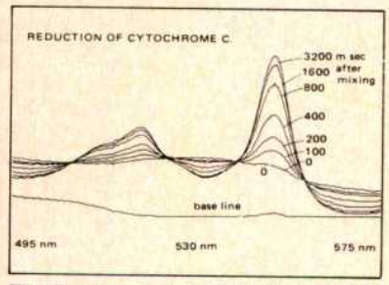
UNION GIKEN

First choice for

STOPPED FLOW

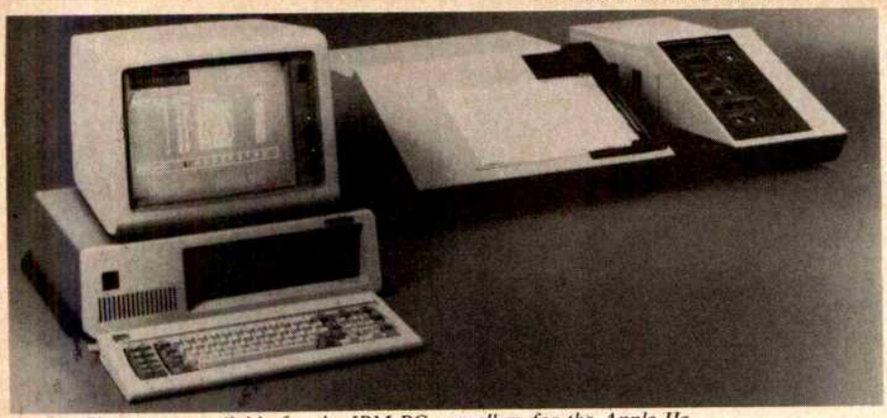


reaction analysis

Union Giken apparatus achieves a dead time as short as ½ millisecond for measurement of fast reactions. Gas pressure is directly applied to the surface of the reactants in each reservoir, mixing and flow being controlled from the end of the system by a high-response stop valve. The RA-401 STOPPED FLOW SPECTROMETER is the ideal match for fast reactions.

The RA-451 DATA PROCESSOR generates a simulated reaction curve from the measured results and automatically calculates the rate constant.

The RA-415 RAPID SCAN ATTACHMENT monitors the change in absorption spectrum during the reaction.



Other attachments are available for T-jump, P-jump, fluorescence and flash photolysis.

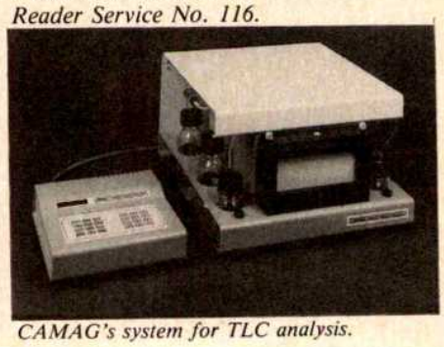
Spectrafile — now available for the IBM PC as well as for the Apple IIe.

● Heyden Data systems' stand features a wide range of software for automating laboratory routines using desktop microcomputers, including the IBM PC. Through the cooperation of the instrument manufacturers concerned, Heyden are able to demonstrate the new Sadtler Digital Spectra Libraries on the stand, where Bruker, Digilab and Perkin-Elmer spectroscopy datastations will be operating side by side. The Sadtler collection, formerly in paper volumes, is a comprehensive library of reference spectra. The new digitized collections allow tens of thousands of spectra to be called to the screen. The digitized libraries are also newly available to run on the IBM PC, which can then be used as a stand-alone datastation. Another new development from Heyden display is the IBM PC version of Spectrafile software, available optimized for either IR or UV spectroscopy.

Stand 620/621, Hall 6-III
Reader Service No. 113.

Rapid amino-acid analysis — the Biotronik LC 5001.

● The latest amino-acid analyser from Biotronik, the LC 5001, can analyse physiological fluids in under 2 hours' complete cycle time, and protein hydrolysates in less than 1 hour. Detection levels are 50 picomoles with ninhydrin and 10 picomoles with fluorescence (OPA) detection. Reproducibility is ± 1.5 at 10 nmoles. The instrument uses a microprocessor programming unit which allows 8 different programs to be stored and run in any sequence and combination. Also on the Biotronik stand is the IC 1000 ion chromatograph, now available in two versions. The basic version is for anion determination only and a second version can handle both anions and cations. Full details of Biotronik's user-workshops and applications support services will be available on the stand.

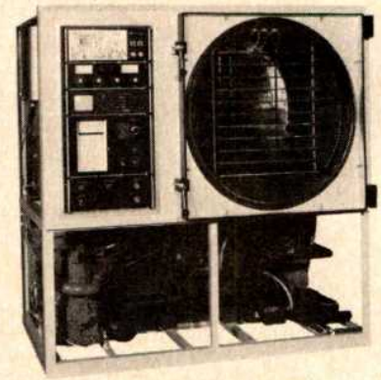


Stand HJ24-25, Hall 6-II
Reader Service No. 114.

● Dyno-Mill, from Willy A. Bachofen AG is the first horizontal, continuous operating agitator ball mill for wet micronization, dispersion and disintegration. In a completely closed system, pumpable suspensions of very low to very high viscosities can be processed. All parts in contact with the product to be ground are easily interchangeable. Models are available with grinding cylinders ranging from 0.3 to 250 litres. A new model in the range, the Dyno-Mill Type KD 20 B, is especially designed for temperature sensitive products and should be suitable for many applications in the pharmaceutical industry and in microbiology. Amongst other items on the stand is the Turbula System Schatz shaker-mixer. This high-performance shaker features three-dimensional overturn motion, with capacities from 2 to 500 litres.

Stand DE-5, Hall 6.
Reader Service No. 115.

● Amongst the new products to be introduced at Achema by CAMAG is a system for the automated multiple development (AMD) of thin-layer chromatograms. With this system reproducibility gradient evaluation can be employed in TLC, making it possible to separate a substantially larger number of fractions than is feasible with conventional development. It also permits separation of mixtures of substances having markedly different polarities. AMD should find applications in environmental analysis, and in all areas where there are complex samples to be analysed. The system, which is fully automatic, consists of a developing unit and developing chamber, gradient mixer, solvent storage bottles, all valves, switching and setting components, and a separate microprocessor control unit.



Stand D10-11, Hall 6-I
Reader Service No. 116.

CAMAG's system for TLC analysis.

● The speciality chemicals manufacturer Johnson Matthey Chemicals is exhibiting an extensive range of chemicals at Achema. Five special display modules will be devoted to the company's Honeycat air pollution control units which control the emission of noxious fumes and odours resulting from many manufacturing processes. The four electronics materials modules will be devoted to ultra-high purity raw materials, and metallizing preparations for the electronics industry. The latest addition to the microbonding adhesives range is a conductive silver-glass paste called AuSub (gold sub), the first inorganic adhesive for high reliability die attachment. AuSub has been designed specifically to replace silicon gold eutectics in hermetic packages. Puratronic elements and compounds are a comprehensive range of high purity materials developed to meet the exacting specifications required by the electronics industry. Typical examples are arsenic, gallium and indium for use in III-V semiconductor crystal growth, bismuth germanate and the tungstate systems for compound oxide crystal growth, and boron trioxide and indium for epitaxy applications. The REacton products, comprising all the rare earth elements, are available in a variety of forms and serve as a useful adjunct to the high purity Puratronic series.

The latest Martin Christ freeze-dryer.

● The latest freeze-dryer from Martin Christ GmbH is a unit in which the ice condenser is integral with the drying chamber. During the drying process the water vapour is frozen, taking the shortest path over the ice condenser surfaces which can be cooled to −75°C, installed on right and left of the product shelves. Using this system the drying time can be reduced by 30% compared with conventional systems in which the drying chamber is separate from the ice condenser compartment. The product shelves, up to 4 m^2 in area, are between −50°C and +70°C in a stepless gradient maintained by circulation of a tempering liquid. So thermolabile substances can be both frozen and freeze-dried successfully. The new freeze-dryer is available as either a stand-alone cabinet or for wall installation.

Stand D11, Hall 6-II
Reader Service No. 118.

● Specac's stand at Achema features a wide range of optical components for laser and optical applications. The high performance Fizeau optical test interferometer (FOTI-100) is designed for measuring optical and mechanical flatness and sphericity. It is being demonstrated with its automatic fringe analysis program. The Fizeau interferometer is a versatile topographic tool, consisting of a well-collimated laser beam which is reflected back from both the surface under test and a reference surface. The two reflected wavefronts are superimposed upon a video detector which then displays the resultant fringes on a high-resolution high-linearity video monitor with push-button magnification. The FOTI-100 has a NeNe laser source (wavelength 632.4 μm) and measures flatness to $\lambda/20$ and spherics to $\lambda/10$. It has an aperture of 100 mm but can be fitted with a beam expander to 150 mm or a beam reducer to 33 mm. A simple two-spot alignment system is used and a hard copy of the displayed interferogram on the screen can be obtained using a Polaroid camera. A wide range of accessories for the FOTI-100 are available including 3 and 5 axis interferometric mounts fitted with a self-centering sample holder. These mounts enable firm but gentle holding of sample and precise positioning which are essential in interferometric testing. A linear or non-linear sliding table together with a horizontal test accessory make for simple measurement of fragile and stress free samples.

The TRIO system from Trivector Systems International for chromatography data handling.

● Achema sees the European launch of the Trivector Systems computing integrator, TRIO. Hardware and software are designed with the chromatographer in mind. TRIO offers one or two channel, synchronous or asynchronous data collection from any chromatograph through a high accuracy V/F convertor. Incoming chromatograms can be shown in real time on the graphics display. TRIO shows great flexibility in scrolling and magnifying data in real time or post-run mode. The post-run display incorporates baseline and peak identification including graphical comparisons. TRIO complements Trivector's TRILAB, TRISTAR and TRINET to give a wide range of equipment for the data processing needs of the modern analytical laboratory.
Reader Service No. 120.

● The French company Biolafitte is showing a selection of fermentation units at Achema. The emphasis will be on two new automatic *in-situ* sterilizable fermenters, one with a capacity of 20 litres, the other 50 litres. Unlike most units of this type, operation is fully automatic. Integral automation in these units prevents handling errors and reduces the need for an operator to a minimum. The technology used guarantees absolute sterility over a very long period and good stability with time. These Biolafitte fermenters are computer-controlled via a network of multiple microprocessors, and the system can also be connected to the customer's computer system. The computer-control systems, like most other components of Biolafitte reactors, are produced in-house by Biolafitte.

Graduate path to entrepreneurship

Graduates should be encouraged to join the ranks of the self-employed. Help is available for those who know where to look.

from Richard Pearson

WITH the labour market picking up rapidly from the doldrums of 1981-82, many graduates will be looking again to the large service and revitalized manufacturing employers for jobs. But what about small firms and self-employment?

In the late 1970s the careers services actively sought out opportunities for graduates in small firms. They did this both to widen the range of opportunities open to graduates and to try and help small firms develop by encouraging them to value a graduate recruit. With graduate unemployment rising to, and exceeding, 12 per cent in 1982, and scientists experiencing even higher rates of unemployment, there was a growing urgency to find new opportunities for graduates both in terms of the type of work they might undertake and by finding new employers. As a result graduates often displaced less-qualified personnel. The fact that graduate unemployment did not rise as steeply as overall unemployment levels and has subsequently fallen significantly as the economy has expanded is testimony both to the flexibility of graduates and to the fact that it has been the higher-skilled jobs that have benefited most from economic expansion.

Indeed, of the half-million extra jobs created in the 18-month period to the end of 1984, two-thirds were for the self-employed, with many of the rest being for part-time workers.

To what extent have, or might, graduates follow the path to such self-employment?

It has been estimated that only about 500 graduates leave higher education each year to launch their own businesses. On degree courses in business studies and management, one might expect a reasonable proportion of graduates to start up their own business ventures, but this apparently is not the case. In fact, it is far more likely to find would-be entrepreneurs emerging from courses in three-dimensional design and other courses in the art and design field, after which self-employment is a normal and expected outcome.

Nevertheless, many graduates do see themselves as having the necessary skills for entrepreneurship and have career aspirations which include the possibility of running their own businesses. A study by Durham Business School[1] has shown that as many students would like to work in small businesses as in large businesses, and that one in four of those with clear career plans wanted to be self-employed or run their own businesses. Indeed, one in twelve had already started doing something about it, either making preliminary enquiries, doing basic design work, or developing a prototype or patenting an idea.

As part of the study, 1,000 students were asked to rate themselves against a set of entrepreneurial attributes ranging from the 'desire for power' to 'the ability to work long hours'. The results were largely positive, although they were less sure of their ability to risk-take and, most significantly, to attract finance.

There has been a lengthy debate as to whether entrepreneurs are born or made, and if the latter, then what factors can be brought to bear to encourage and aid more people to follow the route through entrepreneurship into self-employment and starting their own businesses.

A preliminary vacation course on entrepreneurship showed positive results in terms of encouraging students towards self-employment, although a subsequent work-experience programme seemed to offer a dose of reality and reduced the numbers believing they were entrepreneurs. Thus while the report concluded that enterprise attributes need to be encouraged by developing educational programmes of the 'education for enterprise' kind, to increase awareness at the undergraduate level, more specifically, there was a need to develop special training programmes for enterprise or small business management.

To encourage graduates to consider starting their own business and to foster the entrepreneurial spirit, the Scottish Enterprise Foundation, an alliance of business, academic and governmental interests, launched Graduate Enterprise in 1982. Based at the University of Stirling, its aim is to provide a four-month training programme covering topics such as business planning and strategy, marketing and market research, accounts and book-keeping and sources of finance.

Such has been the success of the Stirling scheme that the number of places has steadily increased from an initial 20 to 60 in 1985. Significantly, there are plans to adopt the Stirling idea in a number of English universities — the first, based at Cranfield School of Management and directed jointly with the Manpower Services Commission, will receive its first intake of 40 graduates this summer. This is for six weeks of formal training as part of an 18-month programme of support provided by Cranfield and the scheme's sponsors — Arthur Anderson, the accountants who will provide financial counselling, and BP, who will undertake product development advice and practical help, with National Westminster Bank providing help and advice on financing problems.

As well as the programme of training, counselling and consultancy, the course participants are also eligible for a £4,000 cash package of allowances during the first 18 months, including a basic allowance of £40 per week during training.

With more institutions starting graduate enterprise initiatives, the number of graduates involved is likely to expand significantly. Not all participants will eventually turn out to be successful. If, however, the business success rate of participants is around the national norm, where the success rate for new business helped by an enterprise trust or similar is believed to be around two-thirds, they will have proved their point — that entrepreneurial skills can be developed and business ideas nourished by an appropriate training programme, and this will be of benefit to both the graduates and society.

There are several incentives for self-employment and starting your own business. First is the contraction of alternatives as the number of opportunities in 'big' business and in the public sector decline. Second, a national policy of favourable publicity and special support schemes. These include low-cost advice, premises and finance, support groups such as enterprise trusts, and training programmes. Finally, the academic institutions themselves are being encouraged to follow a more commercially oriented policy.

Those graduates going into self-employment are still to some extent pioneers and few are likely to hit the jackpot immediately. However, such opportunities do exist and with the continuing constraint on traditional job opportunities, students will be wise to widen their horizons in employment terms; if the number of 'traditional' graduate jobs does shrink in the future, the range of opportunities will surely widen. □

EXPERIMENTAL MELTING OF PERIDOTITE

COMPUTER APPLICATIONS
product review

No other densitometer looks bigger and better

Big enough to handle whatever electrophoresis gels you're using. With better results to match your work. That's LKB's new laser densitometer. UltroScan XL looks at all types and formats, up to 22 × 25 cm, wet or dried. With increased capacity and faster scanning, this big all-rounder gets more work done in a lot less time. And its straight-as-a-laser beam delivers an unrivalled 50 μm resolution with a linear range of 4 OD. Now you can really penetrate closely stacked bands and uncover a wealth of data. Multiple scanning of every sample track gives you reliable average measurement across each protein zone. And when you want fast quantitation by simple programming, the onboard integrator delivers. The scan together with area calculations are presented directly to a standard dot matrix printer. It couldn't look better.

But don't be deceived by good looks alone. UltroScan XL comes with brains as well. The onboard computer lets you exactly define track position and fields of interest, and then automatically scans up to 99 tracks – any way you decide. With gels containing zones of varying intensities from track to track, the unique normalization program lets you compare all your samples in just one run. And talking about comparison, take a look at the large screen monitor. Just tell UltroScan XL what you want, and your video shows you every decision, every command and even a few wishes. Like interfacing with your favourite computer. Or running your own software. You'll evaluate, store, manipulate, display and present your results better than ever.

All in all, it looks like you're getting yourself a scanner that's bigger and better from every viewpoint. Style. Performance. Value. It's worth looking at. Today!

Antibody conjugates

among more than 400 quality products developed and manufactured by

Bio-Yeda

Bio-Yeda offers you a wide range of conjugated antisera including peroxidase, alkaline phosphatase, biotin/avidin, fluorescein, rhodamine and ferritin conjugates to both human and animal proteins.

Bio-Yeda produces conjugates of affinity purified antibodies and monoclonal antibodies, as well as Protein A and PAP reagents.

In fact the chances are excellent that you have already used Bio-Yeda's high quality immunochemical and biochemical products. They are sold all over the world under names you'd recognize on any reagent shelf.

Bio-Yeda's expertise begins with its unique association with the renowned Weizmann Institute of Science, and the company's own powerful R&D facilities.

The products developed and produced by Bio-Yeda include a comprehensive range of conjugates, monoclonals, antibodies to human and animal proteins and antisera to hormones and drugs.

For further information and a detailed Bio-Yeda catalog, call your nearest Authorized Bio-Yeda Distributor, or contact Bio-Yeda directly.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product – not your experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

DOES YOUR DNA SEQUENCE TALK BACK?

Before DNASTAR

After DNASTAR

It will when read into your IBM PC, XT or AT with DNASTAR's SEQ•EASY™ digitizer-talker.

More important the DNASTAR system includes SEQMAN, an advanced gel assembly program to automatically put the pieces of your project together in a single consensus sequence. DNASTAR even helps you design those experiments that are needed to most rapidly finish your sequencing project with its program, STRATEGY. With DNASTAR, sequencing projects don't need to be arduous and frustrating.

DATA ENTRY WITH THE SEQ•EASY™ DIGITIZER

- The SEQ•EASY™ combines an electronic digitizer, voice synthesizer, full ASCII keyboard and lightbox in a single convenient unit.
- To enter sequence data directly into the computer, place the autoradiogram on the SEQ•EASY™ and simply touch the gel bands with the stylus.
- SEQ•EASY™ audibly reiterates each DNA residue as it is entered so the user can focus on the gel—not the computer screen. Mistakes are easily corrected.
- Electrophoresis gel fragment sizes are also easily determined.

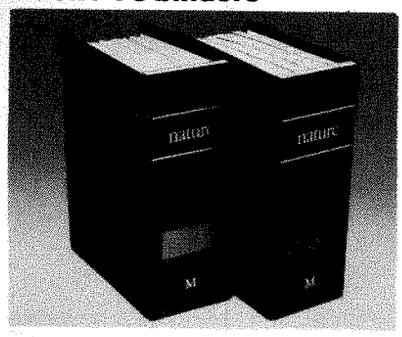
IBM is a registered trademark of International Business Machines Corporation. GenBank is a registered trademark of the Department of Health and Human Services. DNASTAR, DNA★, and SEQ•EASY are trademarks of DNASTAR, Inc.

ADVANCED GEL ASSEMBLY WITH THE SEQMAN PROGRAM

- SEQMAN is a complete sequence project manager. It supports both Maxam-Gilbert and di-deoxy sequencing methods in both random and directed approaches.
- Consensus sequences are assembled automatically from multiple sequence gel runouts.
- A convenient full screen editor is included for adjustment of alignments, if necessary.
- SEQMAN preserves original data files.

COMPREHENSIVE ANALYSIS SOFTWARE FOR MOLECULAR BIOLOGY

- DNASTAR offers a comprehensive software package for DNA and protein analysis with over 37 programs for restriction sites, comparisons, database accession, editors, telecommunications and sequencing.
- Includes the GenBank® and Protein Identification Databases complete with all annotations and the most powerful and sophisticated software to use them.
- Easy operation: single menu, on-line help.



Don't invest in a computer system for molecular biology until you talk to DNASTAR.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

MOLECULAR BIOLOGISTS
DO YOU DO IT BY MANIPULATION?

C.B.L. are the prime producer of high quality Restriction Endonucleases and DNA Modifying Enzymes in the U.K.
Up-to-date facilities and improved techniques enable us to offer these products at highly competitive prices.
We are now selling the following enzymes: —

Ava I	Dra I	Kpn I	Sca I	DNA Pol I
Ava II	EcoR I	Mlu I	Sma I	Klenow
Ban I	EcoR V	Msp I	Sph I	T4 DNA Ligase
Ban II	Eco VIII*	Pst I	Sst I	
Bgl I	Hinc II	Rsa I	Stu I	
Bgl II	Hind III	Sal I	Sty I*	
Bst I	Hpa I	Sau3A I	Taq I	
Dde I	Hpa II	Sau96 I	Xho I	* Exclusive to CBL

Forget the rest **WE ARE** the best.

Reader Service No.16

An essential guide to successful production

This book provides concise and up-to-date information on vegetable crops grown in tropical regions. It contains details of all the factors affecting growth and a clear explanation of techniques that can be applied to increase the level of production. It will be of use to students, extension service staff and research workers who wish to enlarge their knowledge of the range of food crops available for growing in the tropics.
Vegetables in the Tropics provides full information on the cultivation and environmental requirements of about 140 crops.

Hardcover	ISBN *0 333 24266 1*	**£35.00**
Paperback	ISBN *0 333 24268 8*	**£15.00**

H D Tindall is Professor of Tropical Agronomy at the National College of Agricultural Engineering, Silsoe

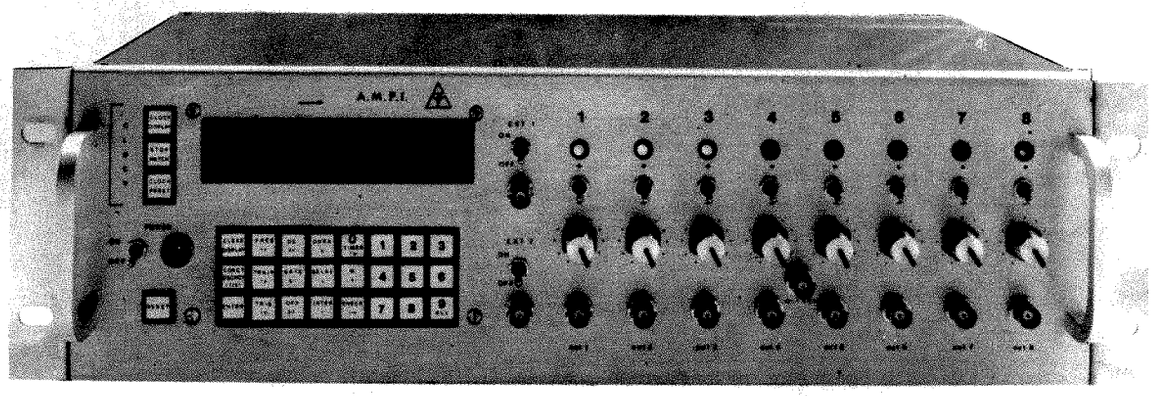
Eight-Channel Programmable Stimulator

Master-8

A.M.P.I.



With Master-8 you only have to set-up the preparation...

...Master-8 will do the rest !!!

*** Microprocessor based, reliable and simple to operate.**

*** Wide voltage and timing ranges.**

*** Very low cost.**

APPLICATIONS — Master-8 controls the activation of 8 different instruments.
FLEXIBILITY — Master-8 is an extremely flexible system (see examples below).
MODES — Each channel can operate independently in the following modes: FREE-RUN, TRAIN (1 to 59,990 pulses), TRIGGER or DC. Two channels can also operate in the GATE mode.
PARAMETERS — Duration, delay or interval time — up to 3999 sec (> 1 hour). Pulse amplitude from -10V to+10V.
PARADIGMS — Eight stored paradigms allow several users to work on the same set-up. Switching between paradigms is very fast (50 msec).
CONNECTIONS — Programmable inter-channel connections (no wires needed). Each channel can be connected with any number of other channels.
MEMORY — After power is switched off, parameters and paradigms are retained by a small lithium battery (AA size, 7 years life).
TRIGGERING — In TRIGGER and TRAIN modes each channel can be triggered **manually** — by one keystroke, or **internally** — from other channels (through the programmable connections). In addition two channels can be triggered **externally** — by external devices. (By connecting these channels internally to other channels, the external input can activate all the channels).
ALSO... — Bilevel pulses, Timer + two extra clocks.
COMPUTER — Master-8-cp can be programmed and controlled by a computer.
PRICE ... AMAZING!!! **Master-8 .....$ 2200.**
Master-8-cp (computer programmable).....$ 2600.

PRICE PER CHANNEL
... $ 275.
... $ 325.

FLEXIBILITY

Many kinds of stimulators and pulse-generators are based on the **"Single Sequence"** method where all the channels are linked to a single trigger source (this source can be triggered internally, externally and in some instruments also manually). Each trigger activates the whole sequence of channels. The disadvantage of this method is that the user can activate either the entire predefined sequence of channels or no channel at all. There is no possibility to trigger individual channels "out of the sequence".
Master-8 is based on the **"Independent Channels"** concept where the channels can operate independently of each other. Each channel can also trigger or be triggered from any number of other channels. Therefore some sequences can run in parallel at the same time. This turns Master-8 into a particularly flexible system.

EXAMPLES OF THE FLEXIBILITY OF THE "INDEPENDENT CHANNELS" CONCEPT:

1) WORKING WITH THE OTHER CHANNELS: While some of the channels are running one sequence, the user can still work independently with the other channels in all the modes as described above. *For instance,* he can give test pulses on FREE-RUN through one channel, operate the air pressure manually by another, have a DC output from an additional channel, receive an external trigger which will activate other channels, etc. The user can do all of this without interfering with the main sequence.

2) EXTERNAL GATE INPUT: Master-8 has the External Gate Input option. This option does not usually exist in the **"Single Sequence"** method since the duration of the external input may be variable, while the sequence has to be fixed. *For instance,* a channel can send trigger pulses to an isolation unit at a preset rate during each input pulse from an external device. The duration of the input pulses can be unknown and variable.

3) PARTIAL SEQUENCE: The user can activate only a part of the programmed sequence. *For instance,* suppose the following sequence: channel # 1 activates a tape recorder, channel #2 triggers the oscilloscope, #3 triggers the calibrator, #4 sends a train of pulses to one nerve and #5 to another nerve. The user can trigger manually a partial sequence (for test purposes) like triggering the oscilloscope and stimulating the nerves, or only one of the nerves, without changing the programmed sequence.

4) 'OR' TRIGGERING: The user can trigger internally one channel by any number of other channels (delayed 'OR' triggering). *For instance,* the user can stimulate one nerve after stimulating each of some other nerves (even if one of the stimulating channels was triggered internally and another through the external input at unknown times).

These examples are only a sample of the many flexible variations by which the user can use Master-8.

UNIPATH

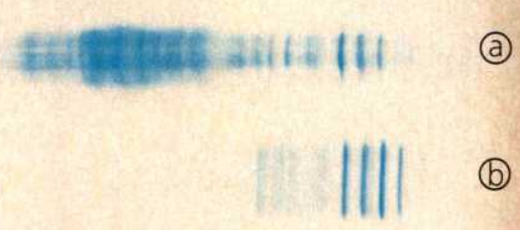
We know they'll behave themselves, we watched them grow up.

Unipath may be a new name to you. But our products shouldn't be. In fact, our comprehensive range of laboratory diagnostic products are already extensively known and used throughout the country.

However, what might not be so well known is that Unipath is a British company, part of Unilever; and that we research, develop and produce an extensive range of monoclonal antibodies in the U.K.

And many of these monoclonals are produced in Serum-Free Media, a unique Unipath process that gives us large quantities of pure monoclonals, and gives you antibodies of a reliably high titre and consistent quality.

Monoclonals in a class of their own



The Unipath range of monoclonal antibodies to **IgG subclasses, T-lymphocyte** and **cancer markers** have been developed through co-operation between British research and British commercial development. We have a close involvement with leading centres such as Birmingham University and the Imperial Cancer Research Fund and have helped them to bring many of their important developments into wider use.

So although our monoclonals come from good homes, good breeding, on its own, can only get you so far. If we are to be sure of their total reliability, we have to keep a constant eye on them. So our production is subject to a level of quality control that ensures none but the best survive.

Optical density measurement and total protein tests ensure a standard concentration.

While PAGE and IEF guarantee the purity and identity of each monoclonal.

Each batch is then tested in appropriate techniques, and these are cross-checked on a regular basis by independent, outside laboratories.

IEF Gel. ⓐ Crude ascitic fluid.
ⓑ Monoclonal antibody from serum-free culture supernatant.

Making the most of their opportunities

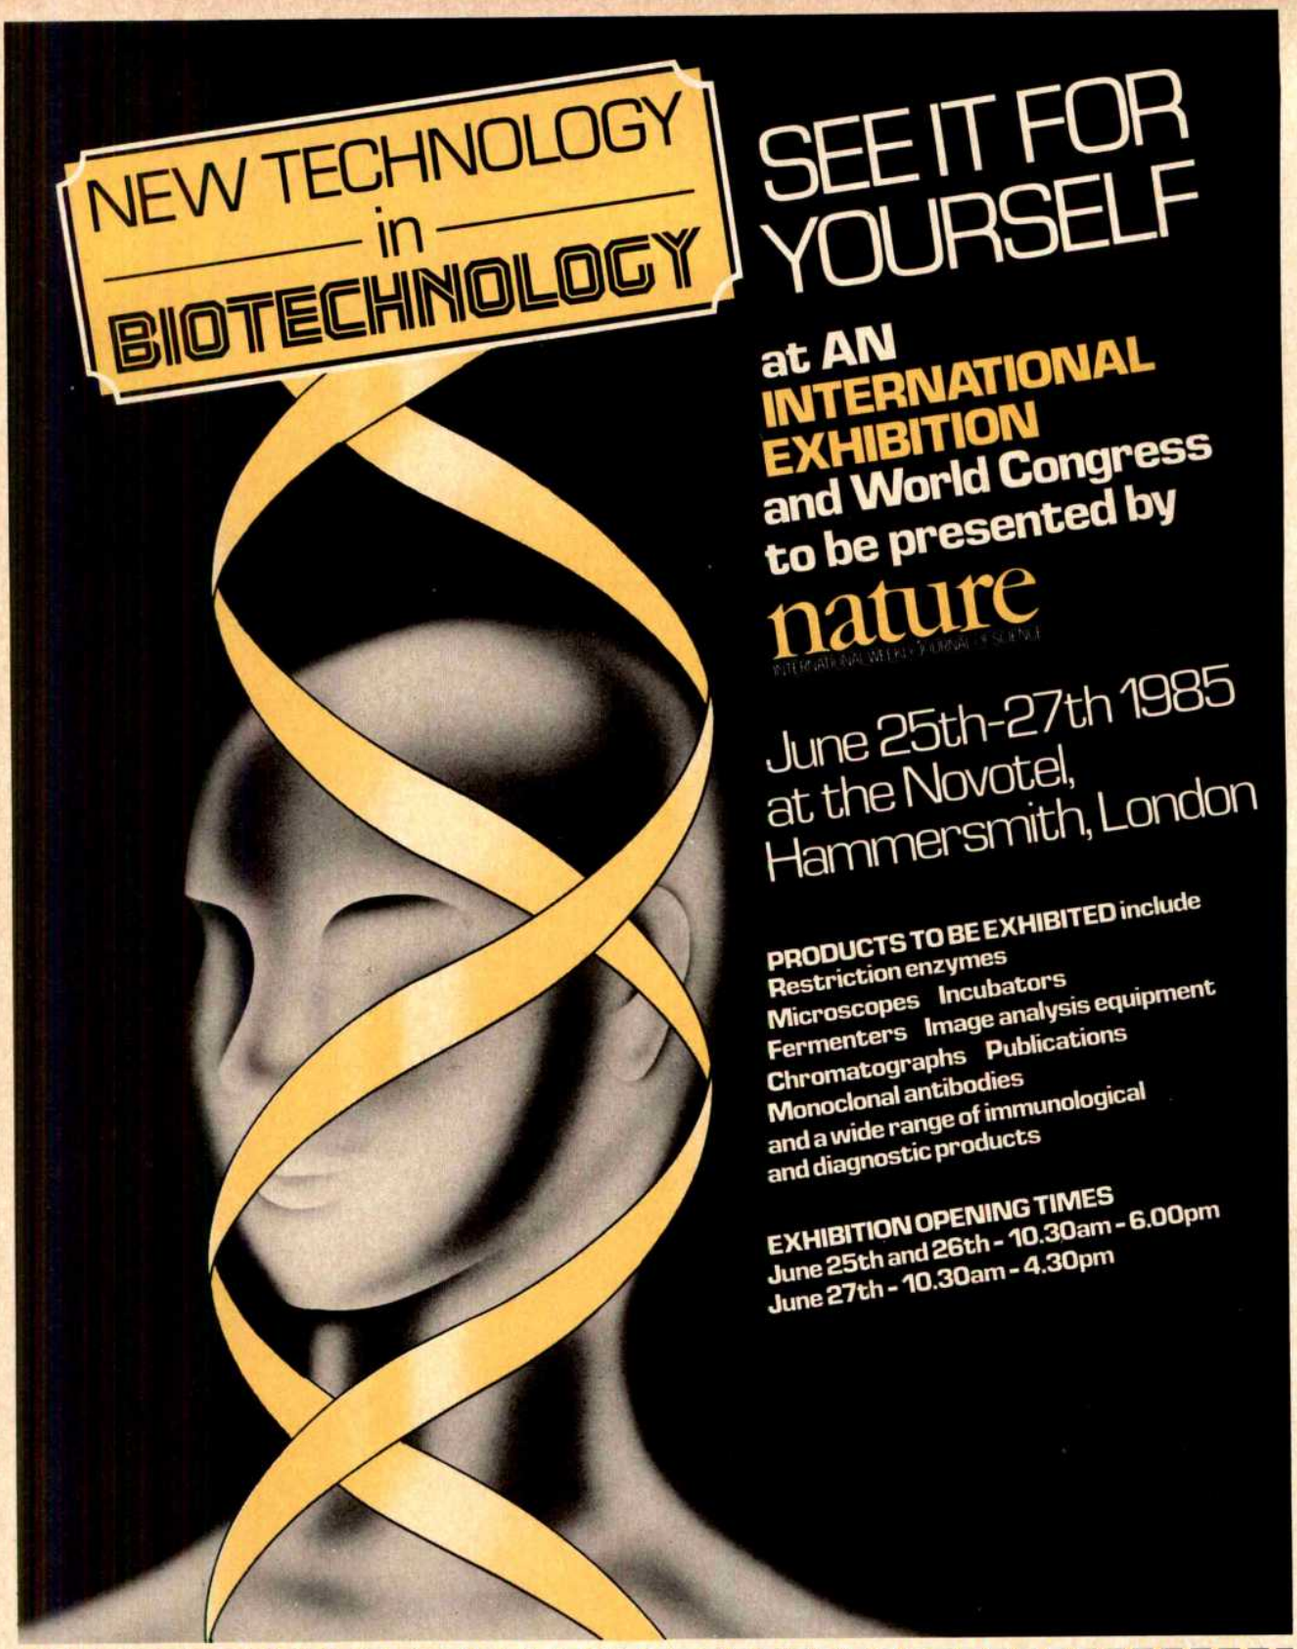
Only when a monoclonal antibody has passed all these tests and we are sure of its reliability, are we ready to pass it on to you.

Our Sales Office can usually dispatch your order within 24 hours.

Our Customer Services Department is always on hand to supply you with the fast, reliable technical information you need.

And, our Representatives are always ready to listen to your comments and pass on your ideas.

After all the trouble we've gone to, it's nice to know our monoclonals are in good hands once they leave home.



UNIPATH

Why settle for anything less advanced?

Unipath bring you a range of diagnostic products for the hospital and research laboratory as well as a comprehensive range of monoclonal antibodies, and polyclonal reagents for use in a variety of techniques. Extensive evaluation and calibration prior to dispatch ensure reliability of results. And our technical and support service means that professional advice is always at hand. Contact Unipath Customer Services Department on (0234) 47161 for further details. Unipath Limited, Norse Road, Bedford MK41 0QG, UK. Telephone: Bedford (0234) 47161. Facsimile: (0234) 218781. Telex: 826784 UNIPAT G.

NEW TECHNOLOGY in BIOTECHNOLOGY

SEE IT FOR YOURSELF

at AN INTERNATIONAL EXHIBITION and World Congress to be presented by

nature

June 25th-27th 1985
at the Novotel,
Hammersmith, London

PRODUCTS TO BE EXHIBITED include
Restriction enzymes
Microscopes Incubators
Fermenters Image analysis equipment
Chromatographs Publications
Monoclonal antibodies
and a wide range of immunological
and diagnostic products

EXHIBITION OPENING TIMES
June 25th and 26th - 10.30am - 6.00pm
June 27th - 10.30am - 4.30pm

ABN

TurboBlot™

PROCESSING SYSTEM

Here is the first fully integrated system designed to hold and process membranes or gels used in blotting and other binding assays. It is used to process membrane-bound macromolecules through probing, washing and drying, even visualization.

The TurboBlot system consists of a processing pouch and holder, base unit with fluid control, and vacuum-flow accessories. The system can process membranes up to 20 x 20 cm, and is useful in many techniques, including:

- **Southern Blots**
- **Western Blots**
- **Dot/Slot Blots**
- **Filter-Binding Assays**
- **Northern Blots**
- **Direct Gel Probing**

Safety and Standardization

Membranes are processed in a disposable flow-through pouch. Without heat sealing! Radioactivity and reagents are contained, thus eliminating spills and contamination. The TurboBlot system provides safety and control unattainable with manual procedures. And better control means greater reproducibility.

Speed and Savings

TurboBlot processing uses minimal volumes of reactants and reagents. As little as one mL of probe! Since washes take minutes, not hours, the TurboBlot system can dramatically increase lab productivity.

Efficient and Effective

Efficient as well as fast, the TurboBlot system provides the low backgrounds needed in many procedures. And the compact, durable design allows handling of more than one membrane at once. The result of over two years of research in cooperation with leading institutions, the TurboBlot system is finding usage in a wide variety of laboratory applications.

So shift from manual processing. Contact ABN for more information, or to arrange a "test drive" of the revolutionary TurboBlot system.

Patent Pending

PROLOG FOR PROGRAMMERS

Feliks Kluźniak and Stanislaw Szpakowicz

With a contribution by Janusz S. Bień

March 1985, 293pp., $47.50/£36.50 (UK only), ISBN: 0.12.416520.6

This book is *not* a primer. It is a reorientation exercise for experienced programmers.

This introduction to PROLOG, its use and implementation assumes the reader has some programming experience and relates the unconventional PROLOG constructs to the programming methods and techniques used in, say, PASCAL thus helping to cross the psychological barrier between the two approaches. The book is practically oriented but avoids irritating the more sophisticated reader with the boring repetitions of obvious, elementary methods and procedures found in many introductory level texts.

The version of PROLOG used is almost identical to the widely accepted Edinburgh PROLOG (the few differences are documented).

FOUNDATIONS OF PROGRAMMING

Jacques Arsac

April 1985, 288pp., $29.50/£23.00 (UK only), ISBN: 0.12.064460.6

Contents: Preface. List of Programs Discussed in the Book. Iterative Programming. Recursive Programming. Recurrent Programming. From Recursion to Recurrence. From Recursion to Iteration. Regular Actions. Program Transformations. The Transformation of Sub-Programs from Recursive to Iterative. Analytical Programming.

FORTRAN OPTIMIZATION
Revised Edition

Michael Metcalf

May 1985, 253pp., $26.00/£20.00 (UK only), ISBN: 0.12.492482.4

Contents: Why Optimize? Computer Architecture. Compiling Techniques. Aspects of Optimization. Basic Optimization. Non-Optimizing Compilers. Optimizing Compilers. The IBM Compilers. The CDC FTN Compilers. Fortran Portability. Vector Processors. Future Fortran. Appendix A: Fortran 77. Appendix B: Layout Program.

LUCID, THE DATAFLOW PROGRAMMING LANGUAGE

William W. Wadge and Edward A. Ashcroft

May 1985, 328pp., $39.50/£30.00 (UK only), ISBN: 0.12.729650.6

Contents: Introduction. Iswim and Algebras. The Language Luswim. Lucid: Luswim with Nested Iteration. Programming in Lucid. Program Transformation. Beyond Lucid. References. Appendix. Index.

Forthcoming titles –

NOW IN PAPERBACK

A Volume in the Computers and People Series

FUNDAMENTALS OF HUMAN-COMPUTER INTERACTION

Edited by Andrew Monk

1985, 303pp., £10.00 (For Sale in UK only), ISBN: 0.12.504582.4 Pbk
1984, $26.50/£22.50 (UK only), ISBN: 0.12.504580.8 Cloth

The aim of this book is to share some of the knowledge acquired from research into Human Computer Interaction (HCI) with those at the sharp end of the design process, principally the systems engineers and programmers. If effective interactive products are to be built and sold, all personnel involved in the process must be aware of the basic design process principles involved: it is not enough simply to consult an HCI specialist when problems arise.

MACHINE-INDEPENDENT ORGANIC SOFTWARE TOOLS (MINT) Revised Edition

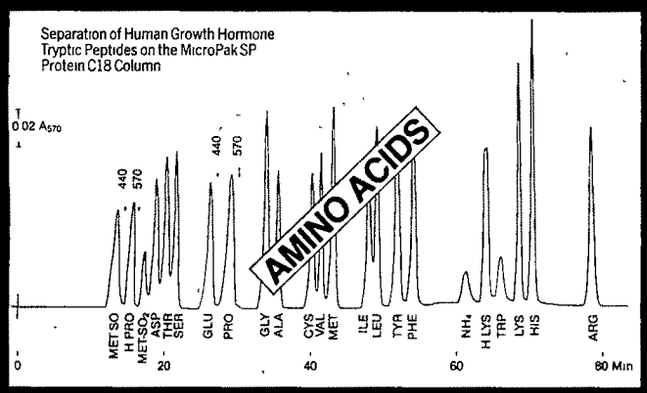
M.D. Godfrey, H.J. Hermans, D.F. Hendry, R.K. Hessenberg

June 1985, 375pp., $30.00/£25.00 (UK only), ISBN: 0.12.286983.4

INTRODUCTION TO LOGIC PROGRAMMING

Christopher J. Hogger

1984, 288pp., $46.00/£35.50 (UK only), ISBN: 0.12.352090.8 Hbk
1984, 288pp., $19.50/£15.00 (UK only), ISBN: 0.12.352092.4 Pbk



Contents: *Representation and Reasoning. Logic Programs. Programming Style. Data Structures. Program Verification. Formal Program Synthesis. Implementation. Broader Contributions to Computing.*

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL SAN FRANCISCO, CALIFORNIA

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homoeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.
Full 3-day registration fee: $375.00
Pay only $325.00 if you register before July 31.

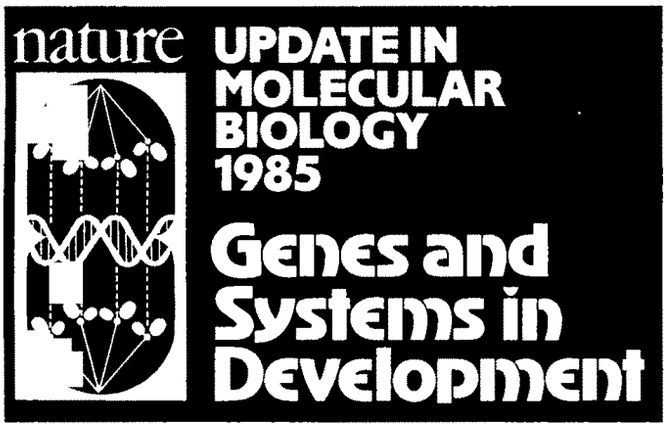
LOCATION

The Sheraton-Palace Hotel located at 639 Market Street is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: $95. Doubles: $105 and $115.

CMEs WILL BE AWARDED



Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL SAN FRANCISCO, CALIFORNIA

TO REGISTER Use This Card. (If card is missing, Call (212) 477-9600). Register Now to Assure Your Place at this Important Event.

CONFERENCE REGISTRATION FORM

Please reserve my place at
Nature Update in Molecular Biology 1985
Genes and Systems in Development.

I wish to reserve _____Conference Registration(s) at **$325.00** per person in the name(s) of:

_____

_____

and _____seats at the Tuesday Evening Dinner at **$29.50** per person in the name(s) of:

_____

_____

_____

Name Title

Co./Institution

Address

City/State/Zip

I understand that as a paid conference participant, I may attend all sessions, and receive all programs and other materials.

My check for $ _____is enclosed.

Charge my credit card as shown.
☐ Amex ☐ VISA ☐ MasterCard

Credit Card # _____

_____

Signature (As it appears on card.)

☐ Please bill me. ☐ Please bill my organization.

Purchase order no. _____attached.

RETURN TO:

Nature Update in Molecular Biology 1985
c/o Nature Publishing Company
65 Bleecker Street
New York, NY 10012

N502

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers	*Topics*
M. Davis (Stanford)	T-cell receptors
U. Storb (U. of Washington at Seattle)	B cells
J.M. Bishop (U. of California at San Francisco)	Oncogenes
M. Ptashne (Harvard)	Regulatory proteins
. Herskowitz (U. of California at San Francisco)	Yeast development
E. Jaworski Monsanto	Plant transformation

DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers	*Topics*
R Palmiter (U. of Washington at Seattle)	Transgenic mice
D. Hogness (Stanford)	*Drosophila* homoeotic genes
M. McGinnis (Yale)	Mammalian homoeotic genes
T. Friedmann (U. of California at San Diego	Human therapy

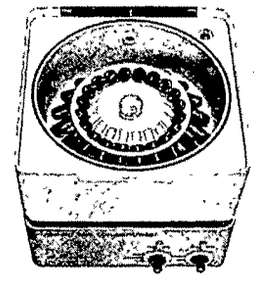
BEAT THE WATER SHORTAGE!

SPEED VAC WATER JET — An efficient vacuum source created by a high pressure pump forcing water through a jet. The preferred method for removing organic solvent vapors since Hi-Vac oil pumps can easily be ruined by condensed organic solvents.



- Vacuum Chambers
- Distillation Apparatus
- Filtering Flasks
- Dessicators
- Fume & Vapor Removal
- Dialysis Devices

SPEED VAC WATER JET

SPEED VAC "NO BUMP" CONCENTRATOR

"NO BUMP" Evaporation System for concentrating samples by volume reduction prior to analysis by Gas Chromatography (GC), High Pressure Liquid Chromatography (HPLC), Electrophoresis, TLE or TLC. 100% sample recovery with Eluates, Hydrolysates, Extracts, and Dialized Solutions... separate volatile organic solvents from Aqueous Solvents in one instrument

"NO BUMP" means no losses and considerable savings if the sample is a valuable one. We guarantee that your isolation technique will yield incomparable results when you use a Speed Vac Concentrator.

U.S. Pat. #422669

What are we doing in the centre of Liverpool?

Imagine the ideal environment for high-tech businesses. A place designed for technologies of the future with scientific skills, research facilities and business expertise.

That's what we've been doing in Liverpool. Creating this environment in the new Wavertree Technology Park and moving Liverpool forward into a new era.

Move into your exclusive factory

To maintain a unique working environment Wavertree is reserved exclusively for high technology companies. It covers 64 acres of landscaped park and rents start at £35 per week. Modern offices and factories are ready for occupation and if you want to construct your own premises, sites are available up to 10 acres.

Maximum Aid

Moving to Wavertree enables you to take advantage of maximum grants. Qualifying companies are eligible for the top Regional Development Grants towards staffing and expenditure on fixed assets. This makes Wavertree a healthy financial proposition.

High technology people and resources

To keep ahead, high-tech businesses need a constant flow of new ideas. This means having the right people and the right back up. In Wavertree you have both with the scientific skills and research facilities of Liverpool's University and Polytechnic.

Road, rail, air and sea connections

Wavertree is one mile from the M62 linking you to the national motorway network. Inter-city rail links and national and international air services give fast connections and Liverpool's Freeport trades worldwide.

A total business package

In Wavertree, we've provided powerful back-up facilities. On-site secretarial and office services, a bank, restaurant, health centre and conference suites. We'll advise on planning permission, construction and grants so that your move goes ahead smoothly and swiftly.

If you've wondered what we were doing in the centre of Liverpool ask yourself what you could be doing in Wavertree. Then ring Stanton Fuller on 051-228 2722.

REDUCE BACKGROUND

With Sequencing Grade Triphosphates From Pharmacia

Ultrapure Deoxynucleoside Triphosphate Solutions

While often overlooked, high quality triphosphates can increase gel clarity considerably, allowing reading of up to 30% further from a single primer site. Pharmacia's solution triphosphates are the most stable, homogeneous and diphosphate free available, and can be used without weighing, neutralization or concentration determination.

2′,3′-Dideoxynucleoside 5′-Triphosphates

Ever since we provided the first commercial dideoxynucleosides in 1977, researchers have relied on our ultra-pure 2′,3′- dideoxynucleoside 5′-triphosphates for the specific chain termination and low background needed in their sequencing.

Keep your results clear of the background.

Parliament's chance to act

This week's debate in the House of Commons about the British government's handling of research and the universities could be a turning point, but the critics must take careful aim.

THE research enterprise and the university system with which it is linked have been badly battered in the past six years, in part because they lost their political friends a long time ago. That is also why it is a long time since the condition of British science was last debated in the House of Commons. (The House of Lords, more leisured but less influential, has been more attentive.) Labour, the chief opposition party, has been crying out for months for a debate about Sir Keith Joseph's part of the enterprise, the universities and the research councils, but has not gone so far as to sacrifice some of its own ration of parliamentary time. Now the government has arranged a debate for Friday, when the House of Commons will be almost empty. Complaints will be aired in a near-vacuum. Let us hope they do not go unheard.

As always, it is important that the complaint should not be overstated. Complainants should at the outset concede a large part of the government's defence. There have been damaging budget cuts, but the Prime Minister has kept her promise, in 1980, to "protect" the direct income of the research councils, the continuing need to reduce public spending notwithstanding. The cuts have fallen instead on the universities in a way that has damaged the underpinning of research, and on the research councils indirectly, by the whittling away of what government departments can afford to spend on commissioned research. The latest cut, by £10 million this year and £20 million next year, in the budget for basic agricultural research, has arisen from the separate dealings between the Treasury and the agriculture ministries, but in a way that suggests the machine is out of control.

Complainants must also concede that there is no reason why research and the universities should have been exempt from the financial pressures to which other government spending has been subject. Most universities are no doubt less efficient than they might be. The research councils are not uniformly paragons of good management (and some of them need urgently to be reorganized). There may even be something in the opinion that because British spending on research and higher education has grown as a result of ill-coordinated decisions to an arbitrary level, it may now be arbitrarily cut back. Put simply, the case against the budget cuts is not that they have been made, but that they have been decided and enforced without much thought for the consequences. Cash limits have become a substitute for thoughtful policy. Paradoxically, the results include not only economies but also diseconomies.

Collapse

The collapse of the dual-support system is the best known diseconomy. Britain has boasted of this device for supporting university research bimodally, by means of project grants from the research councils to researchers whose competence is assured from the recurrent university budget, which provides basic equipment, technician help and other elements of infrastructure. The system has been under strain for at least a decade, as universities have spent their shrinking funds on survival rather than research support. For at least five years, only the strongest universities have been able to support research groups adequately, often by spending precious reserves or by running up debts.

One result is that research council funds intended as research grants must be spent instead on basic research support. Another, more damaging but more common, is that able research groups are frequently ill-provided with research support, even in competitive fields where being second counts for very little. In due course, this imbalance will be put right as the University Grants Committee implements its declared policy of transferring funds within away from less active university departments and even entire universities. But it will be a decade before that policy takes effect. One consequence will be a reduced demand for public research funds, another will be a reduction of the volume of publicly supported research, a third that many creative people will be stranded in places deemed unworthy of public provision of research support. No wonder that people no longer whistle on the way to their laboratories.

The present system is often described as wasteful by its critics, but the remedy now prescribed entails waste not previously imagined. The few thousand researchers from universities and research establishments put out to grass in the past five years have been persuaded to "take" early retirement by financial inducements whose immediate cost (known as that of "restructuring") must be close on £50 million, but whose real cost will be buried in pensions plans for years to come. But the much more serious cost may be that implied by the frequent practice, among those displaced, of working profitably for employers outside Britain. That little irony, with all its implications, deserves a mention on Friday. So, no doubt, will be the diseconomies enforced by the common need to operate educational plant below capacity (because of constraints on student numbers) and to let research equipment lie idle (because operating funds are not to be had). Much of the experience of the past few years is a proof of the diseconomies of contraction.

The British government's rejoinder is that many of these problems would be less serious if only universities would do what they should have been doing all along, and forging stronger relationships with industrial companies. Again, it should be conceded that many (but not all) researchers have been slow to recognize that there may be sources of support other than the government, with the advantages of plurality that would then accrue. But it is unreasonable to expect that such funds will be forthcoming on a scale sufficient to make up for present deficiencies. It would be positively undesirable, and probably an offence against the rules of spending public money, that all hard-pressed institutions should top up their budget deficits in this way. But, in any case, such industrial funds as there may be will probably be distributed on the Matthew principle ("to him that hath ") and will be concentrated among the better off.

Biological manuscripts

Miranda Robertson, Biological Sciences Editor of *Nature*, is now based in the Washington office of *Nature*. Manuscripts offered for publication may be sent, as at present, to either the London or the Washington office; with the benefit of good communications, the speed with which manuscripts are dealt will be independent of the place at which they are received. But authors are asked please in future to send **four copies of manuscripts** intended for publication (one for each office and two for referees).

Closer industrial liaisons will, however, make for a more effective transfer of science and technology from research laboratories to British industry. That has been a constant part of the government's recent opinions. The argument has some force, but not all industrial liaisons with research are desirable or can even be expected to lead to worthwhile commercial enterprises. There are many fields of research (software development, for example) in which it is more important that universities and public laboratories should remain impartial sources of advice for a whole sector of industry And the ragbag of innovations the universities are likely to produce under the new arrangements for their exploitation will not amount to a new industrial pattern for Britain, however valuable some of them may be. There is nothing wrong with the government's wish that British civil science should be more directly productive (than by the provision of manpower) of prosperity, but the naivety of the assumptions often implied about the nature of major industrial innovation suggest that some enterprising university might profitably design an elementary course in economic history for the British cabinet.

Part of the British government's difficulty in this connection is that it lacks machinery for considering these issues in the round. (The Advisory Committee for Applied Research and Development is a group of part-timers which seems to have gone to sleep.) But there are important issues crying out for remedy beyond the immediate boundaries of the Department of Education and Science. The steady erosion of the research budgets of the other civil ministries (other than the Department of Trade and Industry) suggests the government has abandoned the inconvenient Rothschild principle that all ministries should be competent to pursue research. Is it wise that such a state of affairs should come about by neglect?

The problems at the Ministry of Defence are the opposite: research and development costs not much less than the whole of what the government spends on civil science, and is growing. Yet it is now nearly two years since the Prime Minister and the Secretary of State for Defence promised in public that defence research would be made more accessible to British industry. Ministers are busy people, so that it is understandable that such tasks, full of bureaucratic minefields, should be set aside What puzzles and demoralizes those who work in civil research is the zeal with which change has been ordained in the universities and the research councils

Morale

Morale, not money, is what matters in the end. The dictum that the management of success in research requires the creation of an intellectual climate in which good ideas (and their authors) can prosper is none the less true for being over-used. And although research managers (in universities as well as public laboratories) could have done more to protect creative people from the corrosive insecurity that afflicts them, these same people read the newspapers and learn what government spokesmen have been saying about the value of their work Sir Keith Joseph's own white paper on higher education (see *Nature* 23 May, p 270) is the most striking recent example of the genre By dodging questions whose answers might have resolved uncertainty, by its view of higher education and research as an input/output system and by its repetition of a naive view of where industrial innovation comes from, it can only have made British academic researchers think the time had come to go elsewhere. It seems a pity to hazard the productiveness of a whole community for modest savings at its margin.

The British government's weakness is that few of the changes now decreed, many of them well-intentioned, have been carefully thought through. If the proper calculations had been made, change would have been more deliberate, not necessarily slower. And even at this late stage, much could be done to put things right Making the system more coherent, perhaps by appointing a Minister of Science (part-time) would be the best course Taking careful stock in the hope of learning where the research enterprise is heading would be worthwhile. Replacing the policy of management by cash limits with something more intelligent is essential. And, for the time being, the issue is not one of party politics with the general election in Britain two years or so away, the erosion of morale is too rapid to allow an opposition the conceit that it might be possible to wait until then to earn the kudos of reform, for there may be little left by then. □

The tax man cometh

President Reagan's recent reforms go only part of the way towards fairness.

FORMER President Richard Nixon used to speak of various of his administration's actions as "the greatest (fill in the blank) since the Creation"; President Ronald Reagan may thus be forgiven for calling his tax reform proposal merely "the Second American Revolution"

Amid the hundreds of pages of simplification in Reagan's plan is the retention of the research and development tax credit, a provision that, according to independent economists, has cost the Treasury $1,000 million a year to stimulate $700 million worth of research and development. High technology and biotechnology companies, while grumbling along with other industries about the net 25 per cent increase in corporate taxes embodied in the Reagan plan, are full of praise for the wisdom of keeping the research and development tax credit. Sentiment in Congress is mixed, and since it seems unlikely that the Reagan proposal will be disposed of this year, and since the research and development credit is due to expire this year, it will take a special action by Congress to retain it

The tax credit was passed under a banner of stimulating the United States' supposedly lagging investment in the research and development that tomorrow's products will depend upon. Research and development costs had, of course, always been deductible as an ordinary business expense; the tax credit provides an extra bonus — an outright rebate of taxes equal to 25 per cent of a company's research and development spending that exceeds its average outlay in this area of the preceding three years

Yet, as recent studies have shown, the credit has probably done little to stimulate new research. In fact, the credit has in effect been a reward for those companies that had already decided to invest in research and development To those who know the politics that were at work in passing the enabling legislation four years ago, that is probably no surprise

Of course, the sponsors of the legislation did not come out and say so. But the authors of the legislation will now admit privately that the true purpose of the bill was to equalize what the high-technology companies saw as unfair treatment in the tax code. Heavy manufacturers were reaping a windfall through the investment tax credit (which gives a tax rebate of 6-10 per cent on new purchases of machinery) and accelerated depreciation So lucrative have these provisions been that many leading US manufacturers have paid no taxes for years. The high technology companies, whose products depend more on research and development than machines, did less well Thus was born the research and development tax credit.

If tax simplification is truly the President's goal, then such backhandedness has no place in the tax code. The whole story of special interest politics has been one of obscure provisions masquerading as lofty general principles but in fact carefully crafted to benefit group X (sometimes company X) that gave a nice campaign contribution to the right congressman. And the whole principle of tax simplification is the elimination of special treatment for some in favour of lower rates for all.

The administration is proposing to bite the bullet and eliminate the over-favourable treatment of capital investment: under the Reagan proposal, both the investment credit and accelerated depreciation would be repealed. And a new minimum corporate tax would put a further effective cap on the benefits that the heavy manufacturers can reap from capital investment The cause of simplification and fairness might further have been served by going further with the minimum tax, and eliminating the research and development credit □

US medical research

Hughes tops league of US charities

Washington

THE Hughes Medical Institute became the world's wealthiest charity last week when it sold off Hughes Aircraft Company to General Motors for an estimated $5,000 million. Dr Donald Frederickson, president of the institute and former director of the National Institutes of Health (NIH), said the new endowment should allow the institute to more than double the $100 million it currently spends each year on medical research in genetics, immunology, neurosciences and metabolic control.

The sale also marks a further step in the demystification of the institute, which has been something of an enigma even to the scientists it supports. There is no such thing as applying to the Hughes Institute for a research grant; it only gives money to "affiliate" laboratories, of which there are now eighteen, on medical school campuses around the United States. The institute pays the salaries of the 200 or so scientists who work in these laboratories and leases the buildings from the universities. The most recent campus to join the select ranks is the University of California, San Diego and the Salk Institute. Others include Harvard, Yale, Johns Hopkins and Stanford Universities.

Like its mysterious founder, the institute has tended to operate beyond the public view. It has often been criticized for failing to maintain any open criteria (including peer review) for selecting researchers and projects to support.

That has changed dramatically, however, since Frederickson took charge in 1983, following a court fight in Delaware (where the institute is legally incorporated). In the same year, Delaware's attorney general succeeded in removing most of Hughes's former associates from the board of trustees.

The Hughes Institute's $5,000 million places it far ahead of any other charitable organization or foundation. The Ford Foundation, its closest competitor, has an endowment of $3,500 million The Battelle Memorial Institute, which had previously been the largest independent research institute, has assets of only $250 million.

Frederickson estimates that total public and private support of basic biomedical research totals $1,500-2,000 million in the United States; the Hughes Institute will thus be managing some 10-20 per cent of that total By comparison, the budget of NIH is to be $5,200 million next year, though much of that is for clinical and applied research.

Frederickson expects the eighteen existing affiliate programmes to be expanded, as will a new scheme that he initiated to encourage medical students to consider research careers. Under this scheme, to which the institute has contributed $10 million, students can spend one year working at NIH with senior researchers. The 30 Hughes Research Scholars will live and work in the former Sisters of the Visitation Convent adjacent to the NIH campus; the convent is being renovated with the Hughes Institute funds.

Frederickson said the trustees are in the process of deciding whether the institute should continue business as a "medical research organization" — which, under federal tax laws, means it must conduct the research itself — or instead become a private foundation, which would allow it to make grants and expand its horizons to include medical ethics, scientific communication and science education. Medical research organizations are required by law to spend 3.5 per cent of their assets each year exclusively on "continuous conduct of medical research". For foundations the figure is 5 per cent and they must also pay an excise tax of 1-2 per cent on income. In addition, foundations are subject to restrictions on their business activities.

The sale of the Hughes Aircraft Company has also removed the institute's lingering tax problems. Hughes set up the institute in 1953 as a non-profit organization which, on paper, owned Hughes Aircraft — the piece of his industrial empire that now builds defence electronics but no aircraft. For many years the Internal Revenue Service contended that the institute was being used as a tax shelter by Hughes, noting that very little of the Hughes Aircraft profits actually reached the institute. Before 1976, when Hughes died, the institute had never received more than $4.2 million in any one year from the company. Although it was eventually acknowledged that the institute was legitimately engaged in conducting medical research, other tax problems have remained. **Stephen Budiansky**

Japan in space

Carp to loop the loop?

Tokyo

JAPAN'S first astronaut, who may be a woman, is scheduled to blast off in the US space shuttle in early 1988 with a chicken egg, two carp, some soyabean seeds and 20,000 fruit-fly larvae stored in Japan's section of the Spacelab Module. Not intended for eating, these organisms are vital components in a series of life science experiments designed to shed light on the effects of space travel on man.

Details of the fruit-fly experiment were revealed at a symposium held in Tokyo last week. The fruit fly *Drosophila*, which has been subject to more than its fair share of radiation on Earth, will be used to assess the possible effects on human beings of long-term exposure to space radiation, including X-rays, low-energy protons and neutrons and high-energy cosmic radiation. The larvae will be carried in an incubator aboard the spaceship and returned to Earth once they have grown to become pupae. According to Professor Mitsuo Ikenaga of Kyoto University, exposure to radiation should cause curling and/or multiplication of hairs on the wings of the adult insects, thereby providing information about chromosomal changes induced by the radiation.

In a closely related experiment, soyabean seeds will be cultivated on return to Earth and mutations in the adult plants will be easily detectable from the colour of their leaves. But Taro Fujii, head of the Plant Section of the National Institute of Genetics, fears that the degree of exposure to radiation aboard the shuttle may be insufficient to produce mutations.

In a study of space motion sickness, the behaviour and brain-wave activity of two carp in the weightlessness of space will be examined.

A decade ago aboard Skylab, fish were observed to perform strange looping movements for the first 3-4 days in space which corresponds to the duration of disorientation reported by mission specialists. In Japan's experiment, otoliths, which give the fish its sense of balance, will be removed from one of the carp and the effects of light on the fish monitored — normal carp turn their back toward a light source.

A preliminary experiment has already been carried out by Japan's Institute of Space and Astronautical Science (ISAS) in which one carp and three goldfish in a rocket-shaped capsule were dropped from a balloon at an altitude of 30,000 m. During the 20-second free fall, the carp showed promising behaviour, although the goldfish died during the ascent of the balloon. In another experiment a fertilized chicken egg will be hatched and the effects of weightlessness on the chick's bone cells examined.

The Japanese astronaut responsible for looking after these and other experiments has yet to be selected Of 533 applicants for the job, seven remain after three stages of screening by Japan's National Space Development Agency. These seven, including one woman, Chiaki Naito, will undergo final aptitude trials at the Johnson Space Center in Houston, Texas, beginning on 20 June, and around September three will be selected, of whom one will join the space shuttle flight scheduled for 27 January 1988. **David Swinbanks**

European Community research

The RACE is on at last

Brussels

ALTHOUGH prevented by the Italian delegate from formally ratifying any decisions at their meeting on 4 June, the research ministers of the ten countries of the European Economic Community (EEC) nevertheless made several political decisions. The most tangible is the decision to launch the Community's advanced telecommunications programme, RACE (Research in Advanced Communications in Europe). In addition, there were tentative decisions on an advanced informatics programme, Community participation in the European Synchrotron Radiation Facility (ESRF) and a scheme to provide more access to national facilities.

The Italian blocking tactic came in the form of an insistence by Luigi Granelli, Italian research minister and current president of the Council of Ministers, that any proposal should be dealt with as part of an overall package. By that ploy, Granelli had hoped to prise a formal decision from his nine counterparts finally agreeing to set up the Community's tritium-handling laboratory at Ispra in Italy. A decision was blocked by the United Kingdom and France, both of which have national facilities and object to providing further funds at Community level. It now seems likely, however, that the funds will be found out of the existing budget of the Joint Research Centre at Ispra and that President Bettino Craxi of Italy and President François Mitterrand of France will tie up these and other loose ends at their summit meeting in Florence.

A green light for the definition phase of RACE (see *Nature* 28 March, p.309) was given despite problems in the meeting of the Telecommunications Council on 3 June. This phase will cost six million European Currency Units (ECU) and will last 18 months. It will start in July with the construction of a European reference model for an integrated broad-band telecommunications network that will handle voice, data and video transmissions. As a result of pressure from the United Kingdom and West Germany, the funds proposed by the Commission for the next phase will be reviewed at a later date. The present proposal for the Community to cover half the cost is also to be reconsidered with a view to more industrial participation. On French insistence, the French-chaired European Conference of Post and Telecommunication Authorities will receive a large slice of the definition-phase contract

The ministers took a positive view of the proposed location of ESRF at Grenoble and have asked the European Commission to consider possible participation. This move could help to ease present problems over the siting of ESRF (see *Nature* 14 March, p.125 and 28 March, p.305), although since the facility has been proposed in the context of the European Science Foundation, it does not formally come under the jurisdiction of the European Community But because the problems of the siting of ESRF involve rivalry between member states (Denmark, Italy and France plus West Germany) and because the ministers of the Community long ago agreed to some measure of coordination betwen national policies and a definition of joint interests in science and technology, the research ministers agreed to set up a general information and consultation procedure between the ten member states and the Commission.

This proposal, from the Italian president, seems to have met with general approval, both from the larger countries such as the United Kingdom, whose stakes include the Neutron Spallation Source at the Rutherford Appleton Laboratory, and the small countries that fear being left out of the running for important projects and which want fairer geographical distribution of scientific research sites. West Germany, however, raised the question of just how much access to major research institutes would have to be involved. As a first step, between now and the end of the year, the European Commission is to draw up an inventory of national and intergovernmental scientific laboratories and equipment.

Ministers also considered the Italian-backed Initiative for Research in Informatics applied to Society (IRIS). While the idea has the support of member states, they are not yet prepared to pay for it. Meanwhile, the Commission is to carry out a study of IRIS and to hold a seminar on it in December 1985.

Inevitably the French-backed proposal for concerted research in advanced technologies in Europe (Eureka) also came up for discussion at the research council. But apart from admitting that cooperation will include non-Community countries, officials intend to remain tight-lipped until the Milan summit, at the end of June, where European science and technology will be high on the agenda and at which it is hoped that a series of priorities will be agreed.

Anna Lubinska

US veterans

Leukaemia figures in doubt

Washington

A HIGHER than expected leukaemia mortality rate among military veterans who took part in an atomic test in 1957 seems to be a statistical anomaly, according to a National Academy of Sciences study* that examined mortality rates of veterans who were exposed to similar amounts of radiation in other tests. None of these other groups show a statistically significant increase in leukaemia mortality as compared with the general population.

An earlier study by the Centers for Disease Control had confirmed claims by veterans that an unusually large number of men who took part in the 1957 test code-named Smoky at the Nevada Test Site were dying of leukaemia. But the academy study suggests that chance alone could explain the result.

Approximately 200,000 servicemen participated in atmospheric nuclear tests from 1946 to 1962 at the Nevada site and in the Pacific. The academy study looked at 46,000 who took part in five series of tests in which radiation dosimeter badges were issued to the men.

A review of death certificates and medical records revealed that 10 of the 3,554 men present at the SMOKY test had died of leukaemia by 1982 — 2.5 times more than would have been expected for a similar group in the general population. But the study notes that when leukaemia deaths in the Smiky group are compared with the leukaemia deaths in all five groups, the difference is not statistically significant ($P=0.16$). In fact, the total number of leukaemia deaths (46) in the non-Smoky groups was slightly less than expected (52). Likewise, the number of deaths from all cancers in the Smoky group (67) was less than expected (84). Data from the dosimeter badges implies that there should have been only 0.2 excess leukaemia deaths in the Smoky group. So if chance is not the explanation for the leukaemia deaths, then either the Smoky dosimeter data are several times too low or the generally accepted estimates of radiation-induced leukaemia dose—response curves are wrong.

Although the study notes that it is impossible to prove that chance alone explained the anomaly in the Smoky group, it points out that the more comparisons that are made, the more likely it is that one will seem to be statistically significant by chance. This is illustrated by the analysis of all five groups for eight different kinds of cancer. A small excess of prostate cancers is found in one group; but there is a one-third chance that when eight independent comparisons are made, at least one will produce a *P*-value of 0.5 just by chance.

Veterans' groups have called the report "ridiculous" and complain that it makes no sense to compare the atomic veterans with the general population. Because those selected for military service are healthier than the general population, such comparisons minimize health problems in the veterans **Stephen Budiansky**

Energy

Conservation in vogue

FRENCH nuclear power is increasingly abundant, supplies of natural gas from Siberia and Algeria will soon outstrip demand and the French government has set up a study group to invent new ways of using electricity. So why does France need the Agence Française pour la Maitrise de l'Energie (AFME), which last year spent some FF 2,500 million (£210 million) on supporting energy conservation and renewable energies in community housing, industry and research? Because it pays, a team of financial inspectors has concluded.

The inspectors were provided by finance minister, Pierre Bérégovoy, who is now tearing his hair out over the 1986 (election year) budget, due to go before parliament in November but to the Council of Ministers much sooner. Bérégovoy, who, like most finance ministers, is looking for savings, wondered if an increase in energy taxes could be arrange not only to increase revenue but also to save energy

According to AFME sources who have had a chance to look over the inspectors' work, their conclusion — which is not due to be published — is that the "interventionism" represented by AFME is the best way of achieving energy savings. Moreover, AFME itself is the best way of going about the intervention

AFME director-general M. Bernard Laponche says there has always been "tension" over AFME and its policy of investment aids. The tension arises between the "technical ministries" of industry, energy and research, backed by President Mitterrand himself, and the financial sources. Matters may have been made worse by last year's figures which show French primary energy consumption rising by 2 per cent despite AFME's investments, some 80 per cent of which go towards saving or substituting for oil.

But says the ex-trades unionist president of AFME, M. Michel Rolant, his agency's actions saved 2.2 million tons of oil equivalent (t.o.e.) in 1984 in a total of 191.6 million t.o.e., so things would have been worse without AFME. Moreover, the general export trade improved in France last year because of the cheap franc, so a little AFME juggling shows that the French energy bill went down last year — when measured in terms of months of general exports. In 1984, France worked just two and a half months to pay its energy import bill, the lowest since 1980.

In reality, it is still the cost of oil imports that makes AFME's work politically attractive. In its medium-term programme, AFME aimed to produce energy savings over the decade 1981-90 of 40 million t.o.e., more than a fifth of oil imports, of which some 20 million t o e. were to come from improving home insulation and 10 million from industry; renewables, which contributed 3.4 million t.o.e. in 1981, were planned to bring in 10-14 million t o.e. in 1990, mostly from biomass.

There is still a long way to go to reach those targets (set nearly three years ago) but AFME staff are encouraged by the fact that in 1984, for the first time, energy savings profited the balance of payments by more than AFME aid itself — FF 3,000 million against FF 2,500 million. Nevertheless, AFME aid is rarely 100 per cent, so that actual energy-saving or energy-substituting investments in France last year amounted to some FF 11,000 million. This sum may take a considerable time to pay off.

Robert Walgate

Soviet Union

Phobos mission

THE Soviet Union is planning the first-ever mission to Phobos, the larger and inner moon of Mars, in 1988. The two-probe mission will include a close fly-by of the satellite, at an altitude of 50m, during which a laser gun will be fired to stir up surface dust which will then be captured and analysed.

This will be the first Soviet mission to Mars since 1973. Eighteen months ago, *Aviation Week and Space Technology* suggested that the Soviet Union was planning a mission to Phobos, with an approach to within "a few thousand feet" for 1986.

The actual plans for the mission, at present code-named "Mission-F", seem considerably more sophisticated than the *Aviation Week* speculations, which suggested that the Soviets had abandoned Mars flights because of 14 failures or partial failures out of 15 launches or attempted launches between 1960 and 1973. The Soviets, they said, had realized that they could not compete with the plans for the US orbiter/lander mission. In the opinion of *Aviation Week*, the projected Phobos flight was simply a "poor man's asteroid mission".

Perhaps in answer to such smears, the Soviet space planners are trying to make the Phobos mission as international as possible. Sweden's Kiruna Geophysical Institute has been invited to supply an instrument for measuring the energy and mass of solar wind particles around Mars and Phobos. Poland will supply a device to study plasma-waves, similar to those supplied to the Venus-Halley probes now in flight. Bulgarian and West German scientists are developing a special laser mass spectrometer in conjunction with their Soviet colleagues; the East Germans will supply optical systems for filming and map-making and there are plans for a joint Soviet-French device for studying the chemical composition of the martian atmosphere.

Vera Rich

Chromosome libraries

Ploughshares from swords?

Los Alamos, New Mexico

AN ambitious project to create the first human chromosome-specific gene libraries is expected to have covered the entire genome by the end of the year. The libraries, which are being constructed at Los Alamos and Lawrence Livermore National Laboratories, are already attracting strong commercial and scientific interest. Once the project is complete, the rate of human gene mapping will increase by a factor of ten, according to the project team; batteries of probes for chromosome-specific diseases and chromosome-specific stains are among the other benefits expected.

Twelve commercial companies are among the 500 organizations that have already received chromosome libraries from the National Laboratory Gene Library Project. Investigators who receive libraries (free of charge) are asked to inform the project of whatever characterizations they make. The libraries so far available are made using two different restriction enzymes — *Hin*dIII at Livermore and *Eco*RrI at Los Alamos. The cloned DNA fragments are up to 9 kilobases long. Now it is planned to produce 17-kilobase fragments, which are more likely to contain entire functioning genes and will be of greater use in basic molecular biology. Lawrence Livermore and Los Alamos National Laboratories are primarily weapons laboratories and not the most obvious places to find a cloning project. According to Larry Deaven, principal project investigator at Los Alamos, the laboratories were chosen because of their expertise in chromosome sorting, which arose from studies of the effects of radiation on animal cells

The chromosomes for the libraries are extracted either from human fibroblast cell lines or from hybrid human/hamster cells. After treatment with two fluorescent dyes, different chromosomes are separated automatically under laser light. Chromosomes that are not easily distinguished with two dyes are subjected to a third stain: according to Deaven, the chromosomes that are easy to separate have now all been cloned and "we're left with the hard ones". The efficiency of cloning has improved dramatically since the project started in 1983 whereas several million chromosomes were then needed to start a library, the figure is now down to 100,000.

The library project, at present supported by the Department of Energy with a budget of $400,000 this year, will not always remain at Los Alamos and Livermore As soon as both phases have been successfully completed, stocks will be handed over to the National Institutes of Health, which will also maintain information on the libraries.

Tim Beardsley

UK embryo research

Embryo protection bill resurfaces

IN an unprecedented attempt to use the complex rules of House of Commons procedures, supporters of Mr Enoch Powell's Unborn Children (Protection) Bill failed by only the narrowest of margins to reintroduce it into the legislative timetable last week.

The bill, which would effectively ban all experiments on human embryos, was given a second reading in the House of Commons earlier this year by a large majority of 172 (see *Nature* 313, 618; 1985) But, partly because of lack of official government support, the bill was "talked out" at its third reading on 3 May (see *Nature* 18 April p.573). Normally, a private member's bill would, at this stage, have no chance of further progress, so the government seemed set to proceed sedately with its own comprehensive legislation on reproductive technology, based on the recommendations of the Warnock committee (see *Nature* 312, 389; 1984).

In an extraordinary fight back, however, Mr Andrew Bowden MP agreed to reintroduce Mr Powell's bill by exploiting his position at the head of the queue on private members' motions day, 7 June. He included the motion that the House of Lords should finish its scrutiny of the bill, if passed by the Commons, by 5 July, although such a request cannot be enforced

Opponents of Mr Powell's bill, including the Archbishop of York, re-argued their case in the days leading up to the prosposed debate. Dame Mary Warnock saw a "great tide of moral fundamentalism, sweeping across from America" as a genuine threat to proponents of licensed, controlled research. In fact the question was settled in parliament by procedural means. Mr Dennis Skinner MP found and made use of a rule that a motion to make a writ for a by-election (there is one outstanding) takes precedence over any other business, and ensured that the subsequent debate on the subject took hours rather than the usual few minutes. Only 16 minutes of time remained to debate Mr Powell's bill and this was ruled as inadequate to put the case for a debate, which otherwise might have lasted all weekend

Meanwhile, the Medical Research Council and the Royal College of Obstetricians and Gynaecologists last week pressed ahead with their voluntary licensing authority for *in vitro* fertilization (IVF) and embryology techniques (see *Nature* 4 April, p.397) by publishing the authority's guidelines. These are based on the Warnock committee recommendations but each research programme will be licensed and projects will be considered individually. Programmes involving genetic manipulation or implantation of human embryos in other species will be refused licences. The conditions for receiving a licence include:

- Scientifically sound research on the processes and products of IVF.
- Sound reasons why human, rather than animal, tissue is to be used.
- The aim of research must be clearly defined and relevant to clinical problems.
- Pre-embryos (dividing cells up to determination of the primitive streak) resulting from the research should not be transferred to a uterus except to establish a particular pregnancy.
- Signed consent for the use of ova and sperm to be obtained from both donors.
- Fertilized human ova not to be cultured *in situ* for more than 14 days
- The means of embryo disposal to be specified at the outset.

The voluntary guidelines are particularly appropriate now, as the government has announced that it will not introduce legislation in the next parliamentary session — that is, for at least a year. The popular support for Mr Powell's bill means that the government would be under considerable pressure to include his proposal in any legislation it seeks to introduce.

The tortuous progress of Mr Powell's bill contrasts strikingly with the smooth passage of Mr Norman Fowler's emergency bill to ban commercial surrogacy, which received three readings in the House of Commons between 28 March and 13 May. It is due for a second reading the House of Lords on June 14. The bill bans commercial surrogacy agencies and advertising of and for surrogacy services.

Maxine Clarke

Nuclear winter

Cautious support from SCOPE

INVESTIGATIONS into the environmental consequences of nuclear war by the International Council of Scientific Union's Scientific Committee on Problems of the Environment (SCOPE), whose report will be published in September, essentially confirm the results, and reflect the uncertainties, highlighted by the US National Academy of Sciences (NAS) last year (*Nature* 312, 683; 1985). The likelihood of a nuclear winter — a prolonged period of sub-zero temperatures in mid-northern latitudes following a major exchange of nuclear weapons — is thus given further support. This was the message that emerged at the 16th and final workshop of SCOPE-ENUWAR, held at the University of Essex this week and last week. But SCOPE has taken investigations a step further by considering the possible ecological consequences of the potential climatic effects

Paul Crutzen, of the Max-Planck Institut fur Chemie, a member of the steering committee, emphasized that the SCOPE study differs from its predecessors in that, instead of defining an exact war scenario as a starting point, such as the 6,500 megaton baseline case adopted by NAS, it has considered the destruction of a variety of proportions of the available combustible material and the injection of tonnages of smoke into the atmosphere consistent with a several thousand megaton nuclear war. Taken together with the improved general climatic models which now incorporate, in three dimensions, the interactive feedback between smoke plumes and winds, this should enhance the credibility of suggestions of a nuclear winter, according to S. Schneider of the US National Center for Atmospheric Research.

What has become clear, said Crutzen, is that the proportion of soot produced in urban and forest fires following a massive nuclear attack — the "blackness" of the smoke — is perhaps the most important factor. This in turn is dependent on the type of fires foreseen, with urban and industrial areas being more significant than forest fires. At the end of the day, SCOPE's "baseline case" of an attack on 30 per cent of the combustible material in the developed world produces less smoke than the 6,500 megaton borderline case of NAS, but it is blacker, so the resulting effective optical depth is about the same (4.5 for SCOPE, 5.2 for NAS).

The most important unknowns in this estimate are the nature of the smoke from burning oil stocks, and the physical and chemical processes that could affect particles in individual smoke plumes. Little is known of what happens when an oil pool is set on fire, although experiments with pools up to 50m across suggest that the degree of ventilation is the crucial factor in determining the relative proportions of incompletely burnt hydrocarbons, elemental carbon and gaseous oxides, that is, how dirty the smoke will be.

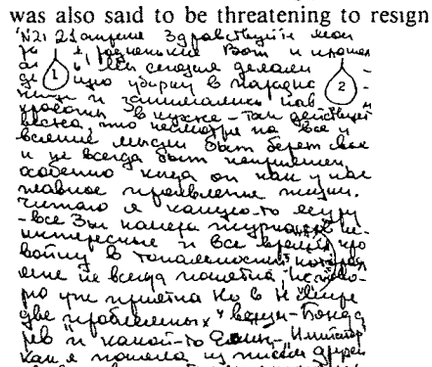
The NAS and SCOPE studies both highlight the lack of knowledge of processes operating in discrete plumes (up to 50 km across). If mesoscale processes tend to cause particles to agglomerate, this will clearly increase the rate of removal by gravity ("rainout") and may affect the optical properties of smoke plumes. Discussions at the workshop focused on two possibly opposed effects. First, the interaction of the plume with local weather conditions may produce more precipitation than is usually foreseen, which could wash the particles out or cause agglomeration, thereby decreasing the amount of smoke reaching the stratosphere. On the other hand, meso and microscale processes within plumes may increase the lofting of smoke, thus putting more particles into the upper atmosphere.

As Barrie Pittock of CSIRO Atmospheric Research, Australia, stressed, escape of soot into the stratosphere could cause marked climatic effects in the

Southern Hemisphere, especially if the war occurred in July rather than January. In particular, interactive climatic modelling suggests a lowering of tropopause (the boundary between the troposphere and the overlying stratosphere) from its present heights of roughly 9 km in high latitudes and 20 km over the tropics to about 4 km over the North Pole and 10 km in the Southern Hemisphere. This, in turn, would mean that a considerable amount of smoke, perhaps 60 million tonnes, enters the stratosphere where it has two climatic effects. First with an optical thickness of 0.1 to 0.5, the smoke results in concomitant reduction in global insolation of roughly 20 per cent. Second, a July war would cause some smoke to drift into the Southern Hemisphere, with the general consequence of reduced global precipitation. In particular, cooling over the Tibet plateau turns off the southwest monsoon. But it has to be emphasized that there remain significant uncertainties in such calculations because the models do not take account of the potential effects of precipitation.

Although much more research is needed into the implications of these climatic changes for both natural ecosystems and agriculture, the results give cause for concern. The areas likely to suffer the worst effects of nuclear winter, the tundra and boreal forests, are the best equipped to cope, noted T.C. Hutchinson of the University of Toronto, because they are naturally adapted to extremes of climate. But the tropical mangrove and evergreen rain forests have no such protection and are very vulnerable to damage by sub-zero temperatures lasting only a few days or weeks.

The effects on agriculture could be even worse, said M.A. Harwell (of Cornell University). What emerges is that although a July war would have more severe immediate and short-term climatic effects than one fought in January, the precise timing may be important. For example the occurrence of just one or two nights with temperatures below 15°C at a critical period in the growing season could wipe out an entire rice harvest. And perhaps as little as a 3°C fall in temperature would be sufficient almost to eliminate Canadian wheat producion. This loss of production, combined with the likely absence of imports, would be disastrous for most of the surviving world population. For example, on loss of imports alone, even assuming 100 per cent of present production, Japan could only feed half of its present population. And most underdeveloped countries appear to have only about four months supply of stored food. If the climatic effects of a nuclear winter in July lie towards the colder end of the range physicists consider plausible, the ensuing lack of food may have a greater impact on the global population than the immediate effects of the nuclear attacks.



Peter Gambles

Sakharov

Mystery on the cards

RELATIVES of Academician Andrei Sakharov living in the United States are becoming increasingly concerned about his whereabouts and well-being. They know of nobody who has seen either Sakharov or his wife, Elena Bonner, in their Gor'kii exile, since February. During April, they received reports that Sakharov had begun another protest fast, and that he was conveyed to hospital for forced feeding on 21 April. A postcard signed by the couple (see illustration) also apparently dated 21 April, which represents them as commencing their spring-cleaning on that date, now proves to have been tampered with in transmission to conceal an original date of 1 April.

During the past two months, there have been many conflicting reports about the Sakharovs, including rumours that they were to be released to the West under an amnesty to mark the 40th anniversary of the end of the Second World War in Europe, and even that they had already arrived in Zurich. (These rumours may have emanated from Soviet official sources, in order to defuse international tensions before the Ottawa Human Rights "Helsinki Review" meeting.) Sakharov was also said to be threatening to resign

The 1 April or 21 April card

from the Academy of Sciences in protest at the passivity of his fellow academicians regarding his plight and that of his wife, who has been refused permission to travel to the West for eye surgery. The arrival on 25 May of the "21 April" postcard initially led the relatives in Boston to have "serious doubts" about the protest fast, and to be more optimistic.

Closer examination, however, revealed a number of anomalies. Because mail from the Soviet Union frequently fails to arrive, Mrs Bonner numbers all postcards (the couple are apparently not allowed to write letters). The card dated "21 April" was numbered 21, but the family had previously received cards numbered 22 (dated 3 April) and 26 (dated 17 April). The latter took two weeks to arrive, while card number 21 apparently took 34 days. Moreover, on card no 21 Mrs Bonner asked if the family had received the birthday presents that she had sent [marked "4" in illustration] while card 22 (3 April) says: "the day before yesterday we received a card from mother saying that the birthday presents for Sasha and Tanya have arrived".

Furthermore, card 21 contains an odd sentence (with a grammatical error in the verb-form) which seems to imply that the snow had melted (past tense) [3] and the gutters were now running with water (present tense). In card 22 (3 April), Mrs Bonner had reported the snow almost all gone, and according to the *Pravda* weather reports there was no snow in the Gor'kii area during the last ten days of April.

The relatives therefore took the postcard, and the thirteen other cards received from the Sakharovs this year, to Charles Gershin, a certified master graphoanalyst in Massachusetts. Gershin knows no Russian, but the Russian cursive script, unlike printed Cyrillic, is based on the Latin alphabet. Examination under high-power magnification, therefore, made it possible for Gershin to detect interference He found that on card 21:

- A "2" had been inserted before the date [1] which had originally read 1 April.
- The alteration of a single letter in line 2 had changed an original "April has gone" [2] (somewhat premature if written on the 21st) to "April has come".
- Similarly the alteration of one letter in the sentence about the snow changes an original "is melting" to "has melted" (with an unavoidable grammatical error).

The implication, therefore, is that the card number was tampered with in order to give the impression that the Sakharovs were leading their "normal" lives on 21 April, from which the logical conclusion would be that something untoward must have occurred. The unconfirmed reports of Sakharov's alleged fast state that he began it on 16 April, so how would the "tamperers" have had to hand the card mailed on 1 April? One possibility is that, for some reason, the censors had decided to withhold this card anyway, and then, when the story of forced-feeding broke on 15 May, the security authorities quickly looked through their stock of recent cards for anything that could be doctored.

The relatives in Boston are now unwilling to commit themselves on any report about Sakharovs, even whether they are alive or dead. According to Dr Efrem Yankelevich, Mrs Bonner's son-in-law, several friends in Moscow apparently received messages from the Sakharovs on 20 May (the eve of Dr Sakharov's birthday), but these were sent by facsimile, which, he says bitterly, "are even easier to forge than a postcard"

Vera Rich

Velikovsky defended

SIR — Yet another book and book review (*Nature* 25 April, p.692) on Velikovsky! Many people who have been warned off reading him by earlier writings must wonder how long this will go on and why. Are there really people who read Velikovsky, and if so, why would anybody with sense read so poorly recommended an author? Perhaps my experience will provide some indication.

I never dreamed of reading Velikovsky for ten years after his first book, *Worlds in Collision*, because the publisher's ill-considered advertisement suggested it was written in support of religious literalism, and scientific critics, rather rabid sounding but presumably competent, spoke unfavourably of him. I only became curious and started to read him when, as a commuter in need of reading matter, I saw some literary figure quoted to the effect that Velikovsky was much a better writer than his critics. He does indeed read well. His sentences flow, one paragraph leads into another and there is never a moment of boredom at which to break off. The catastrophes are vividly described, the reasons advanced for believing in them interesting.

The reasons may, of course, be quite wrong, but that uncertainty is part of the charm of such reading. If a Velikovskyan catastrophe seems an implausible explanation of the sudden death of the Siberian mammoths, one is at least impelled to wonder again what kind of catastrophe it was. If Velikovsky, in spite of some mildly favourable remarks by Einstein, seems unlikely to have discovered electrostatic forces neglected by the astronomers, one becomes curious to know the basic physics, the degree of unanimity of the astronomers, earlier theories (if any) of electrostatics in astronomy, whether, as Velikovsky claims, the recent space probes tell something relevant and whether Einstein had a habit of encouraging eccentrics.

Critics have made much of Velikovsky's alleged appeal to the ignorant and also to his supposed religious motivation, something never documented and which I do not find in his books. He continues to be read because he appeals to the intellect and the imagination, and to a hunger for good writing.

Arms talks

SIR — Your leading article (*Nature* 21 March, p.205) about the Geneva arms talks is a sensible argument about strategies for the negotiations. You recommend that expectations not be built too high too soon, and I concur wholeheartedly. These are the most difficult negotiations we have entered into with the Soviets, because there are three subgroups on space and defence, intermediate-range nuclear weapons and strategic weapons.

These negotiations will take years. Interim agreements along the way would be reasonable objectives. Both sides must be willing to pursue confidence-building measures designed to lessen tensions, and to give hope to people living under each flag that a period of lessening fear is possible, even probable. Improving the atmosphere for negotiations by ratifying the two unratified testing treaties might also be helpful. And trying to understand the issues from the other fellow's side of the table is sound advice indeed. To do that, we need to comprehend more about the other fellow, and even more than that, we need to know the fears, hopes and dreams of his countrymen.

Cuts in wrong place

SIR — I have recently been following the debate over the Natural Environment Research Council (NERC) corporate plan in your pages. I have been interested in the work of some of the NERC institutes, particularly that undertaken by the Institute of Marine Environmental Research (IMER), the Freshwater Biology Association (FBA) and the Institute of Terrestrial Ecology (ITE), all of which are represented in the area in which I am presently but temporarily in residence.

I teach, and have taught, environmental science subjects in colleges and universities in the United States, Canada and New Zealand where I took a similar interest in studies of equivalent organizations. I have found the work of the NERC institutes with which I am familiar to be generally of as high, if not higher, calibre as that in other countries. I was therefore surprised to learn of their present financial predicament. This led me to examine the NERC annual reports which contain the research council's record of diminishing manning levels between 1980 and 1984 (see table). The institutes (plus the British Antarctic Survey, BAS) have suffered a 17.2 per cent drop in manning levels against a 2.6 per cent drop in headquarters (HQ) staff and an actual increase in the NERC Scientific Services (NSS) of 1.5 per cent.

HQ and NSS contribute no commissioned revenue towards the NERC budget whereas the institutes (not including BAS) do offset some of their costs through commissions. As it is also true that NSS is largely administrative in composition, this seems to be a rather good example of the tail wagging the dog. Surely cutbacks should be at least as heavy in the administrative sector (if not greater) as at the business end of the organization? That is certainly a difference between the way things are here in the United Kingdom and in the other countries I have mentioned.

It seems very sad, in light of this, that 1,000 scientific jobs are to disappear when, as seems probable, there should be some slack in administrative staff numbers yet to be taken up.

Value-free science

SIR — Your correspondent M. Diesendorf (*Nature* 10 January, p.92 and 25 April, p.666) writes as if he believes complexity to be an adequate substitute for validity. If he does so believe he is in plentiful company, but errs nevertheless. Of course LD_{50}s are statistical statements; of course it is sometimes hard to isolate the cause of a particular death; of course juries are sometimes flummoxed. So what? Are "values" supposed to creep in under a sort of smokescreen?

As for the suggestion that the statement "I am going to poison my wife" may be "value-free" because it declares intent, let us recall the wise saying that there are times when one good laugh is worth ten thousand arguments.

Mass extinctions

SIR — R.C. Hope (*Nature* 18 April, p.574) complains that he has had enough of the wild speculations of recent years about the extinction of the dinosaurs. As a palaeontologist, I heartily agree.

However, Mr Hope thinks that it is the palaeontologists who are to blame. If he examines the credentials of the speculators, he will find that the great majority of them are not palaeontologists. In offering his own speculation (that the mammals destroyed all of the vegetation and ate the eggs of the dinosaurs faster than they could lay them), he falls into the class of people whom he wishes to criticize. No palaeontologist would subscribe to such a simplistic and biologically unrealistic notion.

Tuning in to neurotransmitters

The slow-acting chemicals that modulate fast synaptic transmission in the nervous system may help to unify the disparate disciplines that make up neurobiology.

FOR too long it has been common to make the analogy between the central nervous system (CNS) and digital computers Both are hard wired, and information is transmitted as digitally coded electrical signals. But in the nervous system communication at the synapses between the neurones is a graded release of chemical neurotransmitters, which have fast, brief effects on very limited targets In the past ten years it has been realized that an enormous number of substances are involved in synaptic communication, subtly modulating the transmission process.

Unlike the fast transmitters, most of the neuromodulators are slow acting, long lasting and often work at long range in very complex ways. A new concept of the nervous system is emerging of hard-wired circuits constantly tuned by chemical signals. This modulation gives the nervous system its flexibility and adaptability to long-term changes, both internal and environmental.

The distinction between the fast transmitters and the neuromodulators was explored on 16–17 May at the symposium that inaugurated the Merck, Sharpe and Dohme Neurosciences Research Centre at Terlings Park, Harlow, United Kingdom. Fast transmitters generally open ion channels in the postsynaptic membrane, thus changing the membrane potential. Onset is rapid and duration brief. As well as acetylcholine at the neuromuscular junction, in the CNS the amino acids glutamate and aspartate seem also to be fast excitatory transmitters, whereas gamma-amino butyric acid and glycine are inhibitory. Modulators, which include the catecholamines noradrenaline, dopamine and serotonin and numerous neuropeptides, act metabolically, like hormones, by activating a chemical second messenger in the postsynaptic cell.

But even this classification is breaking down: it is the postsynaptic receptor that determines the action of a transmitter, not the chemical. Most transmitters have more than one type of receptor; for example acetylcholine has a fast receptor associated with an ion channel and a slow receptor that works through a chemical second messenger. Both can be present on the same cell, so one transmitter can elicit both fast (milliseconds) and slow (seconds or minutes) changes in the membrane potential.

Nor do modulator chemicals all work through the same second messenger. Some alter the activity of adenyl cyclase which in turn changes the level of cyclic AMP; others stimulate the breakdown of phosphatidyl inositides (for review see Berridge, M.J. & Irvine, R.F. *Nature* **312**, 315; 1984). Again the pathway is determined by the receptors and several modulators have two types of receptor, one linked to each pathway.

Receptors for neuromodulators may be on any part of the neurone. Modulators interacting with receptors on presynaptic terminals, seem to modulate transmitter release, possibly by altering calcium flux. Other specific actions of neuromodulators include the suppression or enhancement of various postsynaptic ionic currents, which alter the excitability of the postsynaptic membrane (see *Nature* News and Views, 6 June, p. 454). Some of these effects seem to be mediated by cyclic AMP-dependent activation of protein kinases (S. Waalas, Rockefeller; Nestler, E. & Greengard, P. *Nature* **305**, 583; 1983). Protein phosphorylation could also be involved in the control of synaptic vesicle release; in short-term memory by altering synaptic efficacy; and in regulation of gene expression. The resulting changes in protein synthesis underlie long-term memory, by producing permanent changes at synapses, and in regulating receptor density, which might alter a neurone's sensitivity to transmitters.

Many modulators do not seem to be released at typical synapses but as a cloud that diffuses through the extracellular space to targets that may be over 100 μm away. Here again it seems to be the specific location of receptors that determines which cells respond to such 'parasynaptic' diffuse signals (F.O. Schmitt, Massachusetts Institute of Technology), creating order in place of potential chaos. Unless there is a predictable, structurally defined basis to the CNS, precise responses to such imprecise signals cannot be expected.

Modulators interact not only with fast transmitters but also with each other. Some neuropeptides, such as vasoactive intestinal polypeptide (VIP), work partly by increasing neuronal metabolism and possibly also by increasing local blood flow. Based on evidence for amplification of the action of noradrenaline by VIP, F. Bloom (Scripps, La Jolla) proposed that such interaction could produce very precise spatial control of cortical circuits. The mosaic of VIP-containing cells in the cortex may generate a localized, activity-dependent modulation of the global effects of noradrenaline, so regulating activity in single minicolumns of neurones only 30μm in diameter

Although we are beginning to glimpse the complexity of neuromodulator effects at the cellular level, we know even less about the effect of neuromodulators on behaviour. The most dramatic analysis comes from E. Kravitz and his colleagues (Harvard; Kravitz, E. *et al.* in *Model Neural Networks and Behavior*, ed. Selverston, A. Plenum, New York; 1985) on the control of the reciprocal aggressive and submissive postures in the lobster. In the aggressive posture, all the flexors muscles are contracted; in the submissive, the extensors contract. Both postures can be elicited by injections of monoamine. Serotonin produces the aggressive posture, octopamine the submissive. These modulators act both in the periphery and in the CNS. At the neuromuscular junction both have similar actions producing long-lasting increases in transmitter release and enhancing muscle contractility. In the CNS, however, they have opposing effects on specific groups of motor neurones. The neuronal programmes that result in the two postures are hard wired but the readout of the appropriate programme seems to be facilitated by the particular modulator as it raises or lowers the thresholds of the relevant motor neurones (at least). The cellular mechanisms underlying the serotonin effects in the periphery are already being analysed and the central effects could be pursued to the cellular level. What causes the initial changes in modulator concentrations remains an open question.

It is a serious problem for neurobiological research that the subject is studied on a number of different levels, ranging from the molecular constituents of membranes to whole animal behaviour, and it is difficult to access one level from another. The lobster studies are a good example of the power of neuropharmacology to provide a bridge between these levels. In order to understand how neuronal circuits work, it is now necessary to appreciate the way a chemical messenger can cause short or long-term changes in receptors or channels, which in turn can influence a neurone's excitability, change its metabolism, modify transmitter release or affect the synthesis of new proteins, including receptors.

We are only just beginning to understand these processes, but it seems that the ever-increasing list of neuroactive substances and the complexity of their actions may be the unifying factor so far lacking in neurobiology **Jennifer Altman**

Taxonomy

How many unknown species are yet to be discovered?

from Jared M. Diamond

IN THE nineteenth century, when much of the globe was still biologically unexplored, the discovery of new species was the most exciting and productive area of biology. Today, the study of molecules is the trend, and searches for new species are outmoded. The most vocal searchers, the cryptozoologists, are ridiculed because of their fixation on finding mythical large species — preferably primates, carnivores or long-extinct taxa such as dinosaurs[1].

No one doubts, and few people care, that thousands of small terrestrial invertebrates, cold-blooded vertebrates and plants await description, especially in the tropics. These groups have even yielded major surprises, such as the discovery of the world's largest lizard (the three-metre-long Komodo dragon) in Indonesia in 1912, or of the dawn redwood tree (*Metasequoia*) in China in the 1940s. Nor does anyone question that novelties occur in the abysses of oceans: for example, recent finds of a new family of large-mouthed shark, living crossopterygian fish and a primitive class of molluscs (monoplacophorans) previously thought to have become extinct about 400 million years ago.

Some biologists, undeterred by being unfashionable, continue to scour the Earth for new birds and mammals — but are there any more species to be found? The answer is yes: new birds and mammals turn up every year and occasionally even a species thought extinct is rediscovered. Although not satisfying the cryptozoologists' desire for monsters, these finds have proved important in several branches of biology[1,2]. Tables 1 and 2, assembled from the recent taxonomic literature[3-12], summarize the new finds by region, date and taxon.

Since 1900, 134 accepted new genera of living mammals have been discovered[3-6], mostly in the tropics (Table 1), to yield a current total of around 1,050. From its nineteenth century peak the discovery rate dropped steeply to an asymptote of about 1 genus per year, maintained since 1940 (Table 1). No new genus has been found in the United States since 1916 (the last being the doubtfully distinct bat *Idionycteris*), and none in Europe since 1922 (the vole *Dinaromys* in Yugoslavia).

The 20 mammalian orders are represented unequally in the new finds (Table 2). Eleven orders, all of them poor in species, have contributed no new genera, whereas four (rodents, bats, shrews and marsupials) have produced 90 per cent of the novelties. Re-expressing the results as the ratio of new genera to total number of species to take account of differences in richness of species among orders, these last four orders are still the most abundant, joined by rabbits and whales (new genera/total number of species is > 2.8 per cent). Among the species-rich orders, primates and carnivores have yielded no new genera since 1907 and 1919, respectively. Thus, large terrestrial mammals seem to be almost completely known at the genus level; the recent new species are all to be found among small terrestrial mammals and whales. In fact, no new species of a large terrestrial mammal has turned up since the kouprey, a primitive, rinderpest-resistant species of wild ox, discovered in Indochina in 1937 (ref. 13).

Small does not mean unimportant. Recent finds include two mammals so distinct that they had to be placed in new families. One of these, the bumblebee bat (*Craseonycteris*), found in Thailand in 1974, is the smallest known warm-blooded animal (see figure)[13]. With a weight of only 2 grams and a length of 3 cm, it challenges physiologists to understand how it reconciles small size with heat conservation. The other new family is the dormouse *Selevinia*, found in Kazakhstan deserts, which has the peculiarity of moulting its epidermis as well as its hair[5].

Several genera of supposedly extinct late Pleistocene mammals have suprised zoologists by turning up alive. The Australian mountain pygmy possum (*Burramys*), described in 1896 from fossils 20,000 years old, was caught rummaging behind the garbage pail in the kitchen of Melbourne University's ski lodge in 1966. The 'ice-age peccary' *Catagonus* is now the largest of living peccaries, having been found running in herds through the Paraguayan Chaco[14]. Bulmer's fruit bat *Aproteles* was described from 10,000-year-old fossils, then discovered alive in a New Guinea cave, and finally re-exterminated or driven out by hunters, all within the same year[15].

Among birds only nine new genera (but 134 new species) have been found since 1934 (refs 7-12). As with mammals, the discovery rate plummeted in the first decades of the twentieth century, but has remained steady at around three species per year since 1941 (Table 1). Most of the novelties have come from the neotropics and Africa, with bursts of discoveries occurring when the mountains of New Guinea and the Philippines were explored between 1938 and 1962. In recent years South America, particularly Peru, has been responsible for about half the novelties. Neither Europe nor the United States has yielded a new species in a long time. Disproportionately few of the new species belong to big, conspicuous and wide-ranging orders of birds such as hawks (new species since 1934/total species = 1/287), parrots (1/346), ducks (0/148), charadriiforms (waders and gulls, 0/334) and ciconiiforms (herons and ibis, 0/122). Disproportionately many belong to groups that tend to be cryptic, geographically localized or small, such as owls (4/146), petrels (3/66), tinamous (2/47) and babblers (10/255). Eight of the nine newly described genera are songbirds (passerines) with small geographical ranges.

Although most of the new bird species are similar to previously known species, several are very unexpected in distribution,

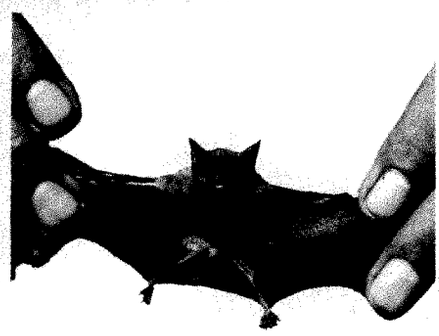

Table 1 New genera of living mammals described from 1900 to 1983 and new species of living birds described from 1934 to 1975

Region	Mammals	Birds
Neotropics	31	56
Africa	27	35

Table 2 Newly described genera of living mammals in each order

Order	New genera/total number of species
Monotremata	0/3
Marsupialia	11/260
Xenartha	0/29
Insectivora	11/391
Scandentia	0/16
Dermoptera	0/2
Chiroptera	26/917
Primates	2/180
Carnivora	2/269
Cetacea	4/78
Sirenia	0/5
Proboscidea	0/2
Perissodactyla	0/18
Hyracoidea	0/7
Tubulidentata	0/1
Artiodactyla	3/185
Pholidota	0/7
Rodentia	72/1,752
Lagomorpha	3/65
Macroscelidea	0/19

The number of new genera are those described between 1900 and 1983, the total number of species are those found up to 1983.

The bumblebee bat *Craseonycteris thonglongyai*, the world's smallest mammal, was discovered in 1974 (photograph courtesy of J. McNeely).

morphology or behaviour. Peacocks were thought to be confined to southeast Asia until the discovery of the African peacock (*Afropavo*) in 1936. The tiny Philippine babbler *Micromacronus*, although in size no rival of the bumblebee bat, is still one of the smallest songbirds. The New Guinea bowerbird *Archboldia* proved to have a uniquely sadomasochistic display: the male crawls prostrate on the bower floor while the female whips her wings over him[16].

In contrast to the case for mammals, there seems to be no bird species described as a fossil and then found alive. But several species thought to be extinct have been rediscovered after a few decades or, in one case (the Bermuda petrel), after three centuries. The most important such rediscovery was of New Zealand's kakapo, the largest and only flightless parrot in the world, and the only flightless bird with a lek mating system[17]. Other notable discoveries were those of the takahe, a flightless grazing gallinule in New Zealand's alpine grassland, and New Guinea's yellow-fronted bowerbird, whose ornate plumage and spartan bower lend support to the transfer theory of bower evolution[18].

In summary, finds of new birds and mammals will please neither cryptozoologists nor those who consider biological exploration an anachronistic waste of time. New species are continuing to turn up at a slow but steady rate, and many areas of biology are being enriched by the discoveries. But, ominously, the rate of extinction of birds and mammals is rising steeply, and will soon overtake the rate of discovery as the destruction of continental tropical rain forests proceeds. Few of the endangered tropical species will have been subjected to much field study before they vanish. Of the very few species thought extinct and subsequently rediscovered, almost all are now endangered. Man seems to find it much easier to bury species alive than to resurrect them permanently from the dead. □

Mathematics

The power of positive thinking

from Ian Stewart

IN 1900 David Hilbert delivered a famous address to the International Congress of Mathematicians in Paris in which he discussed 23 open problems whose solution he considered to be of outstanding importance. C.N. Delzell has now improved the known results of the 17th of Hilbert's problems: the representation of positive functions as sums of squares. This lies at the heart of the algebraic theory of inequalities. For example, the inequality $x^2 + y^2 + z^2 \geq xy + yz + zx$ follows easily from the observation that $2(x^2 + y^2 + z^2 - xy - yz - zx) = (x-y)^2 + (y-z)^2 + (z-x)^2$. Hilbert's 17th problem effectively asks whether a similar trick is capable of proving any inequality involving only rational functions. A rational function is the quotient $f(x,y,z...)/g(x,y,z,...)$ of two polynomials. If a rational function is positive for all real values of its variables, must it be the sum of a finite number of squares of rational functions? Hilbert could prove it for functions of one or two variables, but not in general.

The first solution of Hilbert's 17th problem in the affirmative was obtained by E. Artin (*Abh. Math. Sem., Hamburg* **5**, 100; 1927). In the 1950s the solution was improved by A. Robinson, H. Henkin and G. Kreisel, who used ideas from model theory (the study of structures satisfying axiomatic conditions) and mathematical logic. Recently, Delzell (*Inventiones Mathematicae* **76**, 365; 1984) has refined the solution further, showing that it can be made continuous and constructive.

To understand Delzell's work, consider the simpler case of the Four Squares Theorem. J.-L. Lagrange proved in 1770 that every positive rational number is a sum of four rational squares. For instance, $5/3 = 1^2 + (2/3)^2 + (1/3)^2 + (1/3)^2$. The proof was constructive, in the sense that it provided a definite process for finding the four squares required; but there was no obvious pattern to the final results. Small changes in the rational number concerned could lead to large changes in the summands. H. Heilbronn, however, proved the startling result that a uniform analytical solution exists (*J. London Math. Soc.* **39**,72; 1964), in the following sense. There are four specific complex-analytical functions p, q, r and s, such that for all complex z the identity

$$z = p^2(z) + q^2(z) + r^2(z) + s^2(z)$$

holds. Further, whenever z is rational and positive, then each of $p(z)$, $q(z)$, $r(z)$ and $s(z)$ is rational. Thus, the same analytical formula provides a representation as a sum of squares for any positive rational z.

It is natural to enquire whether Hilbert's 17th problem has a similar type of solution. Because of the generality in which the problem is currently posed, the notion of an analytical solution must be replaced by that of a continuous solution: basically a fixed sum of squares of continuous functions. In 1982, Delzell produced some negative evidence showing that any representation of fourth-degree polynomials in three variables, as a sum of squares of second-degree polynomials, must be discontinuous.

This negative evidence, however, has a loophole. Nothing in the problem specifies that positive polynomials must be represented as sums of squares of polynomials. Indeed, if the problem were to be stated under this restriction, it would be false. T.S. Motzkin (in *Inequalities* ed. Shisha, O., 205, Academic, New York; 1967) has proved that $1 + x^2y^4 + x^4y^2 - 3x^2y^2$ is always positive, but cannot be written as a sum of squares of polynomials. (But it is a sum of squares of rational functions, thanks to some fortuitous cancellations of terms). And Delzell's current work exploits this loophole to obtain a constructive, continuous solution.

To state Delzell's theorem precisely would involve too much jargon, but its spirit is this: there exist specific continuous functions $p_1, p_2, \ldots$ and $r_1, r_2, \ldots$ such that every positive polynomial f can be written as a finite sum of terms $p_i(c,d,\ldots,x,y,\ldots)\, r_i^2(c,d,\ldots,x,y,\ldots)$. Here, p_i are positive numbers, r_i are rational functions, the terms $c,d,\ldots$ are the coefficients of f and $x,y\ldots$ are its variables. The restriction to polynomial f is made to obtain a simple statement of the theorem. The result holds if the coefficients of f are real numbers or, more generally, lie in a 'real closed field'. The case of a general ordered field of coefficients remains open.

A good mathematical problem doesn't just die, nor does it merely fade away into oblivion, but remains a source of inspiration. Hilbert's 17th problem continues to be a part of living mathematics. □

Astronomical clocks

Probing the early Universe with the millisecond pulsar

from Bernard Carr

COULD the millisecond pulsar known as PSR1937+21 provide information about processes that occurred within the first millisecond of the Big Bang? That is one of the intriguing questions raised by the results reported by M.M. Davis, J.H. Taylor, J.M. Weisberg and D.C. Backer on page 547 of this issue.

The millisecond pulsar was discovered in 1982 and immediately gained prominence as the pulsar with the shortest known period; according to theory, its signal must be produced by a neutron star rotating a thousand times a second. What promises to make PSR1937+21 such a useful cosmological probe, however, is that its rotation rate remains remarkably constant: apart from a steady and well-understood increase due to its energy emission, the rate has remained stable to one part in 10^{13} over two years. The pulsar thus provides an extraordinarily accurate clock, of relevance to cosmology in that many processes in the early Universe are expected to produce a background of gravitational waves, which should induce a tiny jitter in the clock's regularity.

To demonstrate the stability of the millisecond pulsar required considerable effort. The radio signal of the pulsar was timed initially with a rubidium clock at Arecibo Observatory but a multitude of corrections had to be applied before its regularity could be inferred. The rubidium measurements had first to be checked for any drifts relative to the master clock in Washington and then corrections had to be made for such effects as the relativistic delay induced by the gravitational field of the Sun, the changing Doppler shift associated with the Earth's motion through the Solar System and the dispersion produced by interplanetary and interstellar plasma. Most of these effects can be estimated with high accuracy and, after they were allowed for and a best fit made for the location, period and spin-down rate of the pulsar, the residual noise is only about one μs over the observation period of two years. This is comparable with the accuracy of the best man-made atomic clocks. The residual noise may in part derive from the fact that the corrections mentioned above are imperfect. If so, improved estimates of these corrections could eventually reduce the residual noise to only 0.1 μs. For the present discussion, the most interesting source of noise would be gravitational waves. If the waves have a dimensionless amplitude h and a period P (assumed to be less than the light-travel time to the pulsar), then they will change the arrival time of the pulses by an amount hP, an effect first pointed out by S. Detweiler (*Astrophys. J.* **234**, 1100; 1979). For a continuous background of waves, this will induce a residual of no more than $h\tau$ over a time τ, because the pulsar is most sensitive to waves with $P > \tau$. (The effects of waves with $P > \tau$ would be largely absorbed into the fit to P and its derivative.) If the pulsar clock has an accuracy of Δt, it can be used to look for waves with period τ and amplitude $h = \Delta t/\tau$.

For PSR1937+21, the limiting amplitude is presently down to 10^{-14}, which means that one may already exclude a density of gravitational waves comparable with that in the microwave background ($\Omega_r \simeq 10^{-4}$ when expressed in units of critical density). However, the limiting density scales as $(\Delta t)^2\tau^{-4}$ and so the sensitivity of the millisecond pulsar as a gravitational wave detector is likely to improve dramatically with time. For example, if the timing residual can be reduced to 0.1 μs, and if this stability can be maintained over 10 yr, the pulsar could eventually search for a background of waves with density as low as $10^{-4}\,\Omega_r$.

The sensitivity of the millisecond pulsar is optimized for waves whose period is comparable with the observation time (a few years). Unfortunately, the most prolific sources of gravitational waves at the present epoch (supernovae and black holes) are likely to produce waves with periods much shorter than this. The one exception might be a population of binary black holes; these would produce radiation through quadrupole losses and could, in principle, be detectable if they were sufficiently numerous (J.R. Bond and B.J. Carr, *Mon. Not. R. astr. Soc.* **207**, 585; 1984). However, the most likely source of gravitational radiation in the required waveband would be processes that occurred in the early Universe.

This can be understood as follows. Cosmic processes which occured at a time t after the Big Bang tend to produce radiation with a wavelength of the order of the horizon size at that time (ct); when one allows for redshift effects, this corresponds to a present period of about $(t_0 t)^{1/2} \simeq (t/10^{-4}\,\mathrm{s})^{1/2}$ yr, where $t_0 \simeq 10^{10}$ yr is the age of the present-day Universe. Thus, the millisecond pulsar can be used to look for waves generated at around 10^{-4} s, providing their amplitude is large enough. It turns out that the condition on the amplitude can be satisfied only if the waves are generated later than a time Δt after the Big Bang. The timing residual of PSR1937+21 thus directly determines how far back we can probe the history of the Universe.

The period around 10^{-4} s is rather significant as it corresponds to the time of the cosmological phase transition at which free quarks transform into nucleons. Recently, E. Witten (*Phys. Rev.* D**30**, 272; 1984) has suggested a rather interesting way in which this phase transition could have generated gravitational waves. If the transition is first order and proceeds by the formation of bubbles which expand explosively, one would expect a gravitational wave background to be generated when the bubbles collide. It is not clear whether the amplitude of the waves would be large enough to be detected by the millisecond pulsar, but it is conceivable. Another consequence of this scenario is that the fraction of the Universe outside the bubbles would be compressed into invisible quark 'nuggets', which might be candidates for the dark matter in galactic halos.

Various other effects in the early Universe could produce a gravitational wave background. For example, if the Universe undergoes an inflationary phase (a period of exponential expansion) at some epoch, characterized by a Hubble rate H, then one expects quantum effects to generate waves with density $(H/M_p)^2\Omega_r$ over a wide period range; here M_p is the Planck mass. This effect was first pointed out by A.A. Starobinsky (*JETP Lett.* **30**, 682; 1979). Such an inflationary stage may occur at around 10^{-35} s after the Big Bang, according to the Grand Unified theories, as a result of the Universe getting trapped in a false vacuum state; it may also occur because of quantum gravity effects. In this situation, the waves detectable by the millisecond pulsar would not be generated at 10^{-4} s, but they would fall within the horizon at 10^{-4} s.

Another possibility is that the Universe could undergo spontaneous symmetry breaking at some epoch, resulting in the formation of cosmic strings. These strings can be thought of as topological defects which are trapped in the symmetrical state and, if some of them form closed loops, they should generate gravitational waves through oscillations. The spectrum of the waves expected is rather complicated (C.J. Hogan and M.J. Rees, *Nature* **311**, 109; 1984) but in the period range relevant to the millisecond pulsar it would be flat with a density of the order of $(T/M_p)\Omega_r$, where T is the temperature of the symmetry breaking. It has been proposed that sufficiently large loops could serve as seeds for galaxy formation (A. Vilenkin, *Phys. Rev.* D**24**, 2082; 1982); this suggestion is already close to being tested by using the millisecond pulsar to look for the associated gravity waves. Although there are other ways of detecting gravitational waves, such as laser interferometry, none is sensitive to waves with a period of a year. Therefore, given time, PSR1937+21 could serve as a unique cosmological probe. □

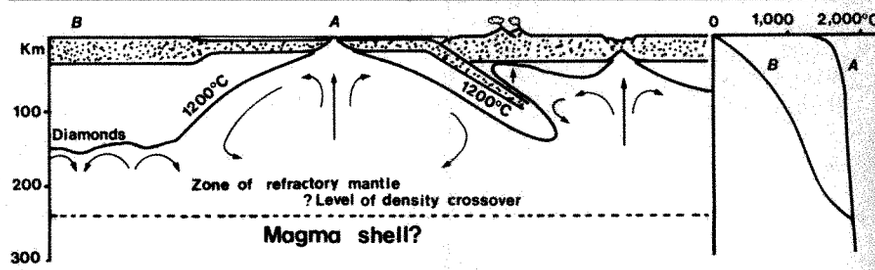
Experimental petrology

Putting the squeeze on rocks

from E.G. Nisbet



CONTINENTS, oceans and the very air we breathe are the cumulative product of aeons of activity deep in the Earth's mantle. Although there are indirect means of investigation available, it would obviously be advantageous to be able to squash rocks in the laboratory to the high pressures and temperatures to which they are subjected in their natural environment. Unfortunately there are technical problems associated with this high-pressure route to the mantle. This has meant that questions such as the origin of komatiites and the controversial suggestions of an Archaean 'magma ocean' have remained unanswered. But recent improvements, especially in Japan[1], have enabled experimenters to attain pressures of up to 30 GPa (as a rule of thumb 1 GPa is equivalent to 30 km of rock) and simulaneously maintain temperatures well over 2,000°C. On page 566 of this issue, E. Takahashi and C.M. Scarfe[2] report results at pressures up to 14 GPa that have interesting consequences for models of the Archaean mantle and thus for the evolution of the Earth.

One of the most interesting problems is how komatiites originated. These lavas, commonly of Archaean age, are highly magnesian (up to 30 per cent MgO) and thus had high temperatures of eruption (over 1,650°C). Crude closed-system mass-balance calculations would suggest that they represent high degrees of partial melting of mantle; a more likely alternative is that they are the product of early melting in an open system at great depth. This suggests that, since the mantle must have been very hot, it was also fairly refractory. Until recently, most experimental work has been with apparatus capable of reaching pressures of 4-5 GPa (40-50 kbar) and 1,700-1,800°C. Both D.H. Green[3] and M.J. Bickle[4], for instance, have shown that natural komatiite magmas must indeed have been very hot. In addition, there have been various suggestions that at great depth the crystalline phases, such as olivine, are lighter than the melt[5-7]. If such a density crossover existed, it may be that the Archaean mantle contained an 'ocean' of dense komatiitic magma at a pressure of about 8 GPa overlain by a thermal boundary layer of floating olivine crystals[5].

These exotic models have provoked a flurry of experimental work using various techniques. At Lamont-Doherty Geological Observatory, E.M. Agee and D. Walker are carrying out experiments at 5-6 GPa and high temperatures, while at California Institute of Technology, shock measurements give strong circumstantial support to the proposed density crossover[8]. Using the 5,000 ton press at Okayama University, Takahashi and Scarfe[2] have melted peridotite under pressures of up to 14 GPa. Their results show clearly that, as predicted[9], early melts close to the peridotite solidus at 5-7 GPa and roughly 1,800°C are komatiitic with over 30 per cent MgO by weight. Equally nice is the confirmation that the slopes of the solidus and liquidus[5-7,10] are roughly as expected, though there is considerable controversy about the extent to which they converge. At high pressure, solidus and liquidus are probably sub-parallel and not greatly different from adiabat of the liquid[10].

The consequences of all this for our models of the Archaean asthenosphere and lithosphere are considerable. Magma ocean models are strongly supported by circumstantial evidence but are as yet quite unproven; however the results reported by Takahashi and Scarfe place severe constraints on thermal and structural models of the asthenosphere. Not the least of these is the interesting contrast between the high temperatures implied by the experiments with komatiite and the strong evidence from diamonds for much cooler temperatures at depths of approximately 150 km beneath ancient continental nuclei. Diamonds have been produced in some numbers from Witwatersrand gold mines (McIver, personal communication) and are generally found in 'pipes' cutting through ancient continental crust. Inclusions in South African diamonds have been dated at roughly 3,300 Myr[11] (although the intrusive pipes are much younger). This would imply a thick continental lithosphere, at least under part of southern Africa, as far back as the Archaean. Taken together with the stability field for diamond, this in turn requires that part of the mid-Archaean subcontinental mantle must have been at a temperature of 900-1,300°C at 4-5.5 GPa[12]. How can this be reconciled with the indications from Takahashi and Scarfe[2] of 1800°C at 5-7 GPa?

The most likely answer is that, rather than being uniform, the thermal structure of the mantle was strongly regionalized[13], with much hotter conditions under oceanic areas than under continents. It may be that under the early continents the lithosphere slowly thickened as the continent aged and cooled, eventually allowing diamonds to form and become frozen into the lithosphere. In contrast, the lithosphere under the oceans would have been much thinner. Regionalized models of this sort with relatively low sub-continental temperatures (1,200°C at 130 km depth) have previously been proposed[5] to account for variations in the nature of erupted lavas. Perhaps under old (3,800-4,000 Myr) continents, the thermal base of the lithosphere was at about 150 km by the mid-Archaean (~3,000 Myr ago), while under zones of rifting and under oceanic areas the base was much shallower. Komatiitic liquids may have ascended in various tectonic settings, ranging from rifting basins within continents to mid-oceanic ridges. Their generation may have ranged from low degrees of open-system partial melting of refractory asthenosphere at pressures of about 5 GPa, to tapping a putative magma ocean. Away from recently active zones of hot asthenosphere, the sub-continental lithosphere must have slowly cooled and thickened.

Cartoon illustrating aspects of some fo the more richly speculative ideas about Archaean tectonics (see refs 5 — 7, 13, 14). Geotherms for locations *A* and *B*.

What next? The Japanese experiments are on the verge of tackling some of the most interesting problems in petrology. No doubt we shall soon know much more about the high-pressure shape of the solidus and liquidus curves and the density relationships at depth. Perhaps soon we will be rid of the uncomfortable notion[5] that a magma shell existed in the Archaean asthenosphere: if it is disposed of we will be left with a better understanding of the mantle's history. If it survives, komatiites may have much to teach us about the chemical differentiation of the planet and the history of the lithosphere and exosphere. □

Oncogenic intelligence

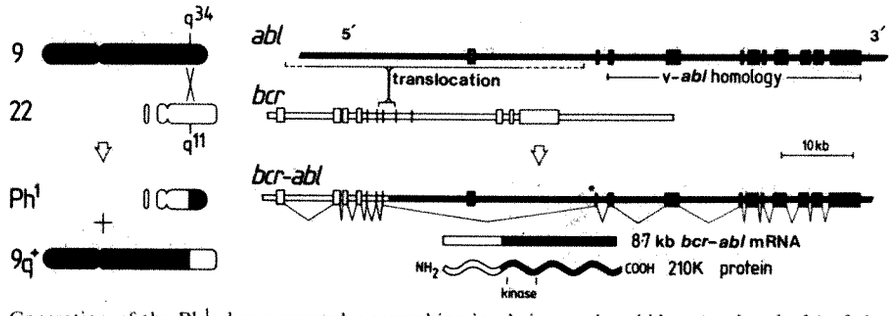
Oncogene activation by fusion of chromosomes in leukaemia

from Jerry M. Adams

AMONG the many chromosomal abnormalities associated with human neoplasms, the most frequent is the unusually small Philadelphia chromosome (Ph[1]), named after the city in which it was discovered[1,2]. The Ph[1] chromosome is present within all leukaemic cells in at least 90 per cent of patients with chronic myeloid leukaemia (CML), an invariably fatal disease characterized by insidious proliferation of the white blood cells[2], and results from a translocation (exchange of arms) between chromosomes 9 and 22. It has long been suspected that this event activates a cellular oncogene which then stimulates uncontrolled proliferation of the myeloid stem cell and its progeny. Increasingly over the past three years[3-9], it is the cellular proto-oncogene *abl* (c-*abl*), identified by its relationship to the oncogene (v-*abl*) of the Abelson leukaemia virus of mice, that has been implicated in CML, but how the *abl* gene might be altered by the translocation has remained obscure. Now, reports by Shtivelman *et al.* on page 550 of this issue[10] and by Heisterkamp *et al.* soon to be published in *Nature*[11], establish that the translocation fuses c-*abl* to another gene in such a way that a novel hybrid polypeptide can be made.

As illustrated on the left side of the figure, the Ph[1] chromosome is generated by a reciprocal exchange between chromosome 9, which bears the c-*abl* gene, and chromosome 22. The exchange always occurs at the same bands (q34 on chromosome 9 and q11 on chromosome 22) and yields an extended chromosome 9, 9q[+], and Ph[1], the shortened chromosome 22.

The c-*abl* gene was first associated with CML when the 9;22 translocation was shown to shift *abl* to the Ph[1] chromosome[3]. More importantly, the fusion region between chromosomes 9 and 22 was later cloned from one CML cell line and shown to involve the linkage of a region of chromosome 22 to sequences near the 5′ end of *abl*. The region on chromosome 22 was subsequently denoted *bcr* (for breakpoint cluster region) because all chromosome 22 breakpoints associated with the 9;22 translocation fell within a 5.8-kilobase-pair (kb) segment[5]. Although breakpoints near the c-*abl* gene were rarely detected (for reasons that will become clear below), nevertheless a novel *abl* messenger RNA of about 8 kb was formed in CML cells as well as, or instead of, the normal 6-kb and 7-kb *abl* messengers. It seemed likely that the new mRNA was derived from the Ph[1] chromosome[6,7] and an *abl* polypeptide with an altered amino(N)-terminal segment, presumably translated from the new *abl* messenger, was also identified[8,9].



These results raised the intriguing possibility that the translocation fuses c-*abl* to a *bcr* gene, as now clearly established by Shtivelman *et al.*[10] and Heisterkamp *et al.*[11]. The emerging picture of the 9;22 translocation is outlined in the figure. The newly identified *bcr* gene[11] is oriented on chromosome 22 in the same direction as c-*abl* on chromosome 9. The breakpoints on chromosome 22 fall within a 5.8-kb region near the middle of the *bcr* gene, spanning two small exons (coding segments)[11]. On the other hand, the chromosome 9 breakpoints may be scattered over a much wider region, as yet poorly defined but often more than 50 kb 5′ to the c-*abl* gene[4,11].

With such a gap between the *bcr* and *abl* sequences, how can a fused *bcr-abl* messenger RNA, and hence polypeptide, be made? It is assumed that a giant primary transcript is made from the entire *bcr-abl* locus and Shtivelman *et al.* plausibly suggest that, by means of the subsequent RNA splicing, the last *bcr* exon before the fusion point always becomes joined to the second *abl* exon (marked with an asterisk in the figure) in the messenger RNA. In this scheme, the first *abl* exon (hatched) will be lost during RNA splicing because it lacks the 'splice acceptor' signal required for splicing to the *bcr* exon. Consequently, in each CML patient there will be a novel mRNA of about 8.7 kb that includes precisely the same *abl* mRNA segment, despite the large variation in chromosome 9 breakpoints. In support of this model, cells from two CML patients with different chromosome 9 breakpoints generate *bcr-abl* mRNAs in which the *abl* segment begins at precisely the same nucleotide[10].

Cells from all CML patients so far examined contain an *abl* polypeptide of relative molecular mass of approximately 210,000 (210K), whereas normal cells contain only a 145K *abl* polypeptide[8,9]; the N-terminal segment of the normal *abl* polypeptide, probably comprising at least 25 amino-acid residues, has been replaced by some 600-700 residues from the N-terminus of the *bcr* product. Since all the *bcr* breakpoints seem to fall after the second or third of several very small *bcr* exons, the predicted *bcr-abl* polypeptides may differ only by the presence or absence of the third small *bcr* exon, which encodes 24 amino-acid residues[11]. It is intriguing to note that the v-*abl* polypeptide encoded by the Abelson virus is also an N-terminal substitution of c-*abl*; 236 amino acids of the viral *gag* polypeptide replace about 113 residues of the normal cellular *abl* product. Hence N-terminal substitution may be critical to convert c-*abl* to a true oncogene.

How the *bcr-abl* gene may promote myeloid cell proliferation is unclear, but one interesting functional difference between it and c-*abl* has already emerged. In common with the v-*abl* gene product, the 210K polypeptide from CML cells has tyrosine kinase activity; that is, it catalyses the transfer of a phosphate from ATP to tyrosine residues in certain proteins[8,9]. At least as assessed by autophosphorylation, the product of normal c-*abl* lacks kinase activity[8,9], although it will probably be found when the appropriate substrates are identified, since c-*abl* bears a tyrosine kinase domain. Thus, it seems likely that the substrate specificity of c-*abl* is altered by the replacement of its N-terminus by *bcr* sequences. Perhaps that modification also explains why the *bcr-abl* gene is most effective in transforming myeloid cells whereas v-*abl* preferentially transforms early B lymphoid cells[12].

Receptors for several growth factors, including insulin and epidermal growth factor, are tyrosine kinases, so it is possible that the normal c-*abl* product is a com-

Generation of the Ph[1] chromosome by recombination between the *abl* locus at band q34 of the chromosome 9 and the *bcr* locus at q11 of chromosome 22. The reciprocal 9;22 translocation is depicted on the left and the corresponding gene structures on the right, with boxes and lines denoting the approximate position of large and small exons, respectively. In the *abl* locus, the position and size of the 5′ exons is not yet well fixed, nor have the breakpoints been located in most instances, although most seem to be a considerable distance 5′ to the *abl* gene. For *bcr*, not all exons have yet been defined but all breakpoints fall within the bracketed region. In the *bcr-abl* locus, a nuclear precursor RNA (thin lines) is presumed to be spliced in such a way that sequences of the most 5′ *abl* exon (hatched) are excised during generation of the illustrated 8.7 kb hybrid *bcr-abl* mRNA, which almost certainly encodes the 210K polypeptide that contains the *abl* tyrosine kinase domain at the indicated region. The molecular counterpart of the 9q[+] chromosome is not shown.

ponent of a growth factor receptor. On the Ph[1] chromosome, the expression of the fused *bcr-abl* gene is presumably regulated by the control elements of the *bcr* gene. Since this chromosomal abnormality features prominently only in CML, which is a neoplastic proliferation of haematopoietic stem cells, it is tempting to speculate that the normal *bcr* gene is expressed primarily in that cell lineage. If the *bcr* product proves to be a cell-surface protein, one intriguing possibility would be that *bcr-abl* represents a hybrid receptor.

While the function of *bcr-abl* is a matter of speculation, there now seems little reason to doubt that its formation by the 9;22 translocation is a critical step in the development of CML. Thus the work on the Ph[1] chromosome, when considered together with the large body of work on *myc* oncogene translocations in lymphoid tumours, makes a strong case that many of the karyotypic alterations found in neoplastic cells represent the activation of specific cellular oncogenes. □

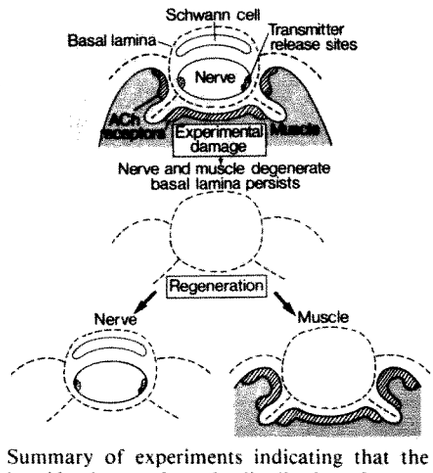
Neurobiology

Orchestration at the synapse



from Clarke R. Slater

CHEMICAL transmission between neurones or from neurone to muscle takes place at junctions termed synapses. Structural specializations at these junctions ensure that receptor proteins in the post-synaptic membrane are aligned opposite the sites in the presynaptic membrane where transmitter is released. How this alignment comes about and is maintained is important for understanding the hardware of the nervous system and its development. Recent work from U.J. McMahan and his colleagues on the neuromuscular junction has shown that the basal lamina is important for determining the distribution of synaptic components on both sides of the synapse[1,2]. In two papers starting on page 571 of this issue, McMahan *et al.* now show that the synaptic basal lamina contains a component chemically very similar to one that causes clustering of molecules that are essential for the functions of the neuromuscular junction[3,4].

The basal lamina is an extracellular layer of material composed largely of a form of the durable connective tissue protein, collagen. A basal lamina sheath surrounds each skeletal muscle fibre and each motor nerve fibre. At the neuromuscular junction, nerve and muscle share a common layer of basal lamina, which has been known for some time to differ chemically from other basal laminae in that it contains a high concentration of acetylcholinesterase (AChE), the enzyme that breaks down acetylcholine (ACh), the transmitter chemical at the neuromuscular junction.

The idea that the basal lamina might influence the distribution of other synaptic components emerged from a series of experiments in which the cells of the neuromuscular junction were destroyed and then either the nerve or the muscle cell was allowed to grow back within the framework provided by the persisting basal lamina sheaths (see figure). When the regenerating nerve made contact with the original synaptic basal lamina, detectable by its persisting AChE activity, it stopped growing and formed the structural features characterizing transmitter release sites[1]. When the muscle cell made contact with the synaptic basal lamina, a high density of receptors for ACh formed in its surface membrane at the site of contact[2]. As no cellular components of the original neuromuscular junction persisted to induce the local specialization of the regenerating cells, it seems that this information could only have come from the surviving basal lamina.

Since those experiments were reported, several groups have been trying to identify molecules that might mediate the effect of synaptic basal lamina on the distribution of ACh receptors. One approach has led to the isolation of a variety of tissue extracts that cause the aggregation of ACh receptors on cultured muscle cells. In other studies, antibodies that specifically label synaptic basal lamina have been raised and used to isolate and characterize the antigens. McMahan *et al.* have effectively combined these two approaches. Starting with a preparation of basal lamina from the electric organ — essentially a stack of giant neuromuscular junctions — of the fish *Torpedo*, they obtained a soluble extract that increased the clustering of ACh receptors on cultured chick muscle cells when present at a concentration of not more than 10^{-10} M. An antiserum against this extract bound specifically to the synaptic basal lamina of frog neuromuscular junction and blocked the ability of the extract to induce clusters of ACH receptors[5].

Summary of experiments indicating that the basal lamina regulates the distribution of synaptic components (adapted from ref.2).

In the first of their present papers, McMahan *et al.* describe monoclonal antibodies, raised against the same extract, that have effects similar to those of their original antiserum[3]. In the second paper[4], they report that the extract causes the formation of clusters of AChE activity, as well as clusters of ACh receptors. It is very likely that both clusters occur at the same sites. Because of the specificity and homogeneity of monoclonal antibodies, it can be concluded that a component of the basal lamina at the neuromuscular junction is closely related to, if not identical with, molecules that can induce the clustering of the two most essential molecular components of the synaptic surface of skeletal muscle cells. By studying the effect of these antibodies on the developing neuromuscular junction, it should be possible to define the role that the basal lamina plays in synapse formation.

The antibodies will also be useful in exploring whether the cluster-inducing molecules are present in the central nervous system and how they are produced during synapse formation. Recently, Kelly and his colleagues described a glycoprotein component of the basal lamina of the electric organ[6]. This molecule is also present in the spinal cord of *Torpedo*, where it is located specifically in the electromotor neurones and is transported in their axons to the periphery. This raises the possibility that, during development, growing motor nerves add components to the basal lamina of the muscle fibre that cause aggregation of the molecules constituting an effective synapse. Experimental tests of such hypotheses should soon be possible. □

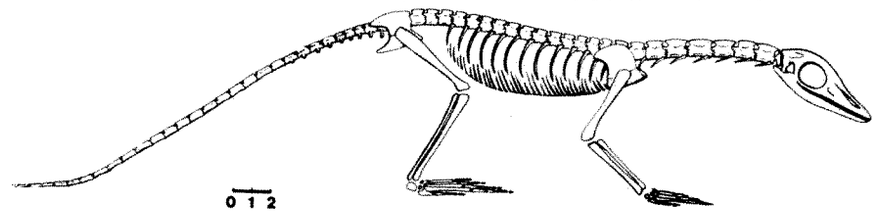
Palaeontology

Cosesaurus — the last proavian?

from Andrew R. Milner

SYSTEMATIC palaeontology sometimes seems to resemble a scene from Dante's Purgatory. As fast as some palaeontologists tidy fossils into manageable groups, others describe new specimens which cannot possibly fit into any orthodox framework. Some supposedly bizarre or highly significant fossils do maintain their status on investigation but it has been, and still is, the fate of many an oddity to prove on revision to be more mundane than its original author(s) believed. One such fossil, *Cosesaurus aviceps*, now seems to have joined the ranks of the demoted.



Cosesaurus was first described a decade ago as a proavian from the Middle Triassic of Spain[1]. It is a small fossil reptile, 14 cm long, represented only by a single negative impression of a skeleton having a large-eyed skull with a relatively large brain case and beak-like jaws, a lizard-like body with a long tail and hindlimbs slightly longer than the forelimbs. It was originally described as possessing a furcula (the 'wishbone', or fused clavicles), a bird-like pelvis and traces of feather impressions; this evidence, coupled with the bird-like skull, led one of its discoverers to propose it as a closer relative of true birds than *Archaeopteryx*[2]. *Cosesaurus* was even used to support the hypothesis of a Palaeozoic origin for the birds, quite distinct from dinosaurs or even archosaurs[3]. It seemed in many respects to be the much-sought arboreal 'proavis' rendered tangible at last. But *Cosesaurus* never gained many adherents as a protobird and, in recent years, the relationship of *Archaeopteryx* and the birds to the dinosaurs has been thoroughly supported by cladistic analyses[4,5]. This has left *Cosesaurus* in an increasingly anomalous position.

A recent reassessment by Sanz and López-Martínez seems to have found a more modest position for *Cosesaurus* in the phylogenetic framework of the sauropsid reptiles[6]. They dismiss the supposed furcula and feathers as overinterpretation of a poor specimen, and argue that the remaining suite of derived characters support a position within the Prolacertiformes, a group of Permo-Triassic diapsid reptiles, once thought to be early lepidosaurs, but more recently argued to be primitive relatives of the archosaurs[7,8]. Sanz and López-Martínez also note *Cosesaurus's* specific resemblance to the much larger *Macrocnemus*, a prolacertiform from the contemporary and ecologically equivalent Monte San Giorgio in Switzerland site (see figure). They suggest that other characteristics, including the superficially bird-like head, are juvenile: if *Cosesaurus* is related to *Macrocnemus*, it must be either a hatchling or a dwarf species, the former being more likely in the absence of other evidence.

This identification agrees well with the presence of the nothosaur genera *Lariosaurus* and *Nothosaurus* in the same beds at both localities and implies that the Spanish site has simply produced a small sample of the Monte San Giorgio-Muschelkalk vertebrate association — a typical Middle Triassic Tethys coastal fauna. The general resemblance between the skull of *Cosesaurus*, a juvenile archosauromorph, and that of a bird is an interesting reminder of how progenetic dwarfing may have reshaped the typical archosaur skull to result in the avian skull.

Another strange reptile recently and more cautiously described from the Upper Triassic of Italy[9] is less likely to suffer such a reduction in status. *Megalancosaurus preonensis* is also tiny and has a superficially bird-like head, long cervical vertebrae, a very long forelimb with five short digits, each bearing a deep blade-like claw, slender ribs and an archosaur-type pelvis. Only a preliminary description has yet been published and only a tentative position within the thecodont-grade archosaurs has been proposed.

Some recent analyses of archosaur relationships place the pterosaurs and dinosaurs close together within the archosaurs[10] and, judging by such characteristics as are visible, *Megalancosaurus* seems to belong close to, or within, the pterosaur-dinosaur clade. Its small size, peculiar claws and slender forelimbs suggested to its describers that it was arboreal and, indeed, its forelimb is distinctly reminiscent of that of the Colugo or flying lemur, the patagial gliding mammal of south-east Asian forests. Could it be that this fossil represents a conservative patagial gliding relative of the pterosaurs?

Reconstruction of *Macrocnemus bassanii* from two specimens from the Monte San Giorgio site, Switzerland, studied by B. Pryer. The limb bones are shown in their longest view, without an anatomical perspective. Scale in cm. Drawing by N. López-Martínez (from ref. 6).

Geochemistry

Uses for synthetic fluid inclusions in quartz crystals

from Edwin Roedder

FLUID inclusions are small droplets of the fluids from which crystals grew and are found in many minerals, both natural and synthetic. In natural gem minerals, fluid inclusions diminish their clarity, and hence their value; in synthetic crystals they detract from the useful mechanical, electrical or optical properties for which the crystals are grown. Why then should anyone want purposely to form microscopic inclusions of fluid in otherwise optically clear quartz crystals? Yet S.M. Sterner and R.J. Bodnar[1] have recently developed a procedure to do just that, and have shown that the resulting inclusions are valuable in a surprisingly wide range of geochemical and mineralogical studies that may help us to understand better the natural processes that may have taken place millions of years ago.

Sterner and Bodnar start with solid cylinders of clear quartz, cut from a fluid-inclusion-free natural crystal. These are heated and then cracked by quenching in water. The cracked but still intact cylinders are dried and sealed into thin-walled noble-metal capsules with the starting materials appropriate to generate the desired fluid composition under the experimental conditions. The collapsible capsules are then subjected to external pressures of 0.5–7 kbar, while being heated to 200–850°C, for periods of between 3 hours and 87 days, before being quenched.

During the time at elevated temperature and pressure, the fractures in the quartz crystal are healed by dissolution and recrystallization of the crack surfaces, thereby decreasing the total surface energy

(see Fig.1). In so doing, small portions of the capsule fluid are trapped within the new growth — samples of the fluid, sealed in single crystal quartz 'bottles'. Thus, these new synthetic inclusions are analogous to the 'secondary' inclusions found in most natural quartz crystals (Fig.2). (Secondary inclusions are those that are formed by the healing of fractures in a pre-existing crystal; the fractures are generally caused by external stress.) Possible applications include the study of inclusion-trapping mechanisms and rates, post-trapping changes and even the determination of phase equilibria and pressure, volume and temperature data on otherwise experimentally very difficult high-temperature, high-pressure hydrothermal systems.

The full range of uses for these synthetic fluid inclusions has yet to be explored but applications already discussed by Sterner and Bodnar[1] have some fascinating ramifications. Fluid inclusions, both natural and synthetic, undergo various phase changes on cooling after becoming enclosed in their crystal host. Henry Clifton Sorby (the 'father of fluid inclusions') showed in a study 127 years ago[2] that these phase changes could be observed and reversed in the laboratory while heating the host crystal under the microscope. The most common phase change observed occurs because liquids shrink at a much higher rate than crystals. Thus, if a hot liquid is sealed into a relatively rigid, fixed-volume crystal 'bottle' and then cooled, differential shrinkage of the liquid relative to the crystal will cause the formation of a vapour bubble in the liquid. Sorby observed the point when this bubble disappeared in a crystal on a microscope heating stage and used it as a measure of the temperature at which the cavity had originally been sealed, perhaps millions or billions of years earlier. Each tiny inclusion (and ordinary white quartz may contain 10^9 inclusions per cm^3) is, in effect, a built-in thermometer, recording the temperature of a past event.

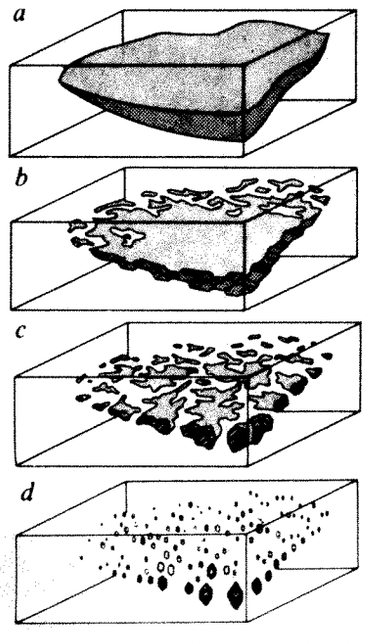

Fig. 1. Stages in the healing or 'necking down' of a crack in a quartz crystal resulting in secondary negative crystal inclusions (from ref.3).

Sorby's proposal to use fluid inclusions in this manner — only one of his many brilliant ideas — was, and still is, the subject of considerable discussion. In part this debate arose because the geothermometric data from fluid inclusions contradicted some of the preconceived notions of the day, and in part becaue of the difficulty in assuring that the geological conditions under which an inclusion formed actually fulfilled the several relatively simple but necessary assumptions behind the method. Previous studies of fluid inclusions accidentally trapped in synthetic industrial quartz crystals, grown under approximately known conditions, have verified the general validity of the concept of inclusion geothermometry. Several minor problems have, however, interfered with the widespread use of the method, not the least of these being, surprisingly, that of accurately calibrating the microscope heating stages[3]. The most common application of synthetic inclusions made with the new method may be as a device for calibrating instruments.

In the years since Sorby's work, fluid inclusions have provided much geological information in addition to temperature. Measurements of phase changes visible under the microscope at temperatures ranging from roughly −190°C upwards, and with appropriate conditions and caveats, can provide data on the density, pressure and the major solute and solvent compositions of the fluids at the time of trapping. Most of these data simply cannot be obtained from any other source. In the search for metallic ore deposits, it would obviously be desirable to understand the chemical processes that resulted in transport of the ore metal to the site of the ore body, and its precipitation there. This requires an understanding of the chemistry of the ore-forming fluid; with a few rare exceptions, the only samples we have of these fluids are in microscopic fluid inclusions.

The past few decades have seen a tremendous increase in studies of the composition of such inclusions. Many of these have involved the use of new methods of ultramicrochemical analysis, such as laser-activated micro-Raman spectroscopy and laser-ionized mass spectrometry. Such methods have attempted to overcome the difficult problems of extraction and chemical (or isotope) analysis of major and trace constituents of these inclusions, without serious loss or contamination. In addition to the exceedingly small total sample size (frequently less than 10^{-9}g) usually available, the problem of finding suitable analytical standards has been particularly limiting. The new synthetic inclusion technique developed by Sterner and Bodnar permits the preparation of optimum standards for both microscopy and chemical analysis — inclusions of the same size range, enclosed in the same host mineral and containing fluids of known density and composition.

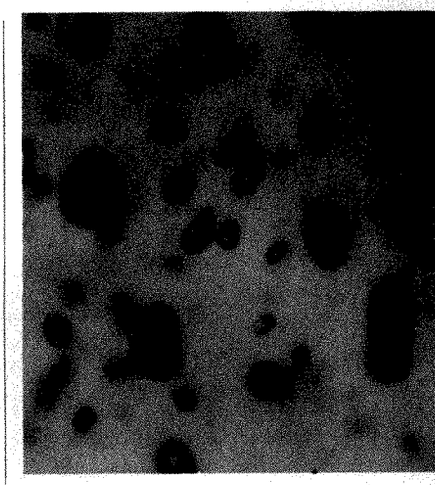

Fig. 2. Synthetic fluid inclusions in quartz. Those with small bubbles (of CH_4) initially trapped liquid and are now dominated by a carbonate; those with large bubbles trapped vapour and are largely CO_2: ×156 (photomicrograph courtesy of S.M. Sterner and R.J. Bodnar).

Still another application, with a particularly exciting potential, is the use of these synthetic inclusions in studies of the physical chemistry of otherwise difficult chemical systems. N.P. Ermakov[4] pointed out 35 years ago that fluid inclusions in transparent minerals are unique miniature 'visual autoclaves', permitting visual observations of high-temperature and high-pressure phase assemblages and critical phenomena. Bodnar and Sterner[5], have explored the use of synthetic inclusions in pressure-volume-temperature studies of hydrothermal systems and Bodnar *et al.*[6] have gone on to show how valuable these synthetic inclusions can be in the determination of the phase-equilibrium properties of the system H_2O-NaCl to 1,000°C and 1,500 bar. Such data are necessary for an understanding of several important groups of ore deposits that have formed from hot, extremely saline fluids and are also useful in understanding the mechanism and energetics of volcanic eruptions such as that at Mount St Helens in May 1980. Conventional experimentation is very difficult because these fluids are exceedingly corrosive. The use of even a few trial runs with synthetic inclusions to locate the critical fluid parameters could reduce the effort involved in larger-scale experiments, or the inclusion technique itself could even be used for the entire phase-equilibrium study. □

Oncogenes homologous to steroid receptors?

SIR — Why do tumours that initially respond to hormone therapy lose their hormone responsiveness after a time and then grow autonomously? This problem is of great clinical importance, for instance in breast cancer where tumours that diminish in size after endocrine treatment almost invariably recur and then tend to progressively become nonresponsive. The discovery that many breast cancers consist of subclones of oestrogen receptor (ER)-positive and ER-negative cells[1,2] suggests that tumour progression is the survival of the 'fittest' and most malignant ER-negative subtype. But where do the hormone-independent cells come from in the first place? Are they always present or are they derived from hormone-dependent cells? And how do these manage to survive and proliferate if they do not have the oestrogen receptor to give the proliferation signal?

A general opinion is that the cells become hormone-independent because they have *lost* the receptor. But such cells should be unable to respond to their growth stimulus and so be eliminated from the tumour population. A more plausible alternative is that they have undergone a change that leads to their getting a growth signal even in the absence of ER. Steroid receptors interact with nuclear DNA at enhancer regions that regulate the transcriptional activity of structural genes[3-6]. Perhaps a mutation in the enhancer leads to its activation of genes without the need for receptor to bind to it. However, it is unlikely that the loss of ER and a mutation in the enhancer region would occur simultaneously. We suggest another explanation, namely the appearance of aberrant receptor-like molecules that bind to DNA and give a proliferation signal even in the absence of oestrogen. Unlike traditional ligand-binding studies, the recently developed monoclonal antibodies to steroid receptors have made it possible to seek aberrant receptors which fail to bind steroids in hormone-independent cells. Thus immunoreactive glucocorticoid receptors have been detected in receptor deficient (r^-), nuclear-transfer deficient (nt^-) and nuclear-transfer increased (nt^i) mouse lymphoma variant cells[7], and this has been confirmed by the finding that mRNA encoded by the receptor gene in these variants is changed quantitatively and qualitatively[8]. In r^- cells, one allele is altered so that no product is detectable with either steroid or antibody, while the other allele produces an immunoreactive polypeptide devoid of hormone-binding activity[7]. In nt^- and nt^i lymphoma cell variants, the glucocorticoid receptors react abnormally with DNA[9,10].

What are the structural changes associated with this abnormal functioning of receptors? In nt^i cells part of the receptor domain is missing which binds neither steroid nor DNA, but which may modulate nuclear association and DNA binding[7,11]. The complexes of this aberrant receptor plus glucocorticoid might still bind to the biologically relevant sites on DNA, but without this leading to transcriptional regulation[7]. Thus, the available evidence suggests that the loss of steroid responsiveness of some tumour cells may be due to alterations in the steroid receptor gene(s) leading to altered receptor molecules which may act in a 'deregulated' manner and induce cellular proliferation even in the absence of hormone. The mutated (possibly truncated) receptors may or may not retain the hormone binding properties. A biological precedent for this possibility has been described: the v-*erb-B* oncogene product is homologous to the non-hormone-binding domain of the epidermal growth factor (EGF) receptor and cells expressing the gene do not require EGF for continued growth[12]. This raises the question: are there oncogenes that are homologous to parts of the steroid receptor genes and confer loss of hormone dependence upon cells that contain them? If so, is this because the aberrant receptors produced by these oncogenes have the ability to bind to DNA without the aid of steroid hormones, and so give a continuous growth signal to the cell? In this area of research progress is rapid, so we should soon know the answer to these important questions.

The infectious nature of prions

SIR — In a recent discussion of prions, Colin Masters emphasized that a protein-only composition of prions requires protein-directed protein synthesis for its replication, "a situation which could be without precedent in biological science"[1]. While protein-directed protein synthesis may be without precedent, protein-directed protein-folding has a precedent and could explain the infectious nature of prions.

Geneticists are well aware of this as a mechanism of gene effect in a number of dominantly inherited diseases. For instance, it is possible for an abnormal collagen to cause a severe phenotypic abnormality[2], while a non-expressing mutant for collagen is recessive[3].

This is most easily interpreted if the mutant collagen gene directs the synthesis of abnormal collagen chains which affect structure in a negative way through mixed trimers with the normal collagen chain which are conformationally abnormal. One can also see the effects of the conformation of one protein chain on another in haemoglobins (for instance, the increased affinity of a normal alpha-chain for oxygen secondary to a mutant beta-chain such as occurs with haemoglobin Ypsilanti[4]).

These protein interaction examples involve inherited genes, but the interaction is not transmitted, that is the original information is in the genome but the negative effects of an altered protein conformation are limited to the zygote. However, it is possible for such altered conformational information to be transmitted from generation to generation. The best example I know of this is that of reversed cortical pattern in *Paramecium*. Beisson and Sonneborn showed some years ago that a reversed patch of cortex could be transmitted to descendant *Paramecium* through its usual binary fission[5]. Thus, the cortex grows by the addition of macromolecules to a pre-existing cortex, receiving positional information from the pre-existing cortex. When the positional information is altered in some way, in this case by microsurgery, the abnormal information can be transmitted.

It is conceivable that the prion could be a normal protein in an abnormal configuration which, upon transmission to a new host, leads the normally synthesized protein to start folding in the new abnormal configuration, thus multiplying the number of prions in the abnormal conformation. In order to account for the increase in the number of prions, one must assume that the prion is not permanently affixed to the aggregate of 'new' and 'old' prions and that the new configuration of this normally-present protein is highly stable. Of course, such a hypothesis does not help us understand how prions cross cell membranes and the other aspects of infectivity which must be taken into account to explain their transmission between individuals.

High-precision timing observations of the millisecond pulsar PSR1937+21

M. M. Davis*, J. H. Taylor†‡, J. M. Weisberg†§ & D. C. Backer‖

Long-term studies of pulse arrival times for the pulsar PSR1937+21 yield estimates of the pulsar's period, spin-down rate and celestial coordinates with unprecedented accuracies. Over periods exceeding six months, this pulsar is at least comparable in stability to the best man-made atomic clocks. Our results place a limit on the energy density of low-frequency gravitational waves in the Universe.

SHORTLY after the discovery[1] of PSR1937+21, we began a series of high-precision measurements of the arrival times of its pulses, observations being made at intervals ranging from daily to once every several weeks since November 1982. Data collected in the first two weeks were sufficient to determine the period derivative of the pulsar[2]. Here, we present an analysis of a much longer span of data obtained between 28 November 1982 and 12 October 1984. The results confirm our earlier measurements of the pulsar position, period and spin-down rate, improving their accuracies by several orders of magnitude.

The microwave beam that produces the pulses from PSR1937+21 has a constant angular width of ~15° and is rigidly attached to a spinning neutron star with rotational kinetic energy of almost 10^{52} erg. The measured rate of energy loss, presumably resulting from low-frequency electromagnetic radiation and particle acceleration in the pulsar magnetosphere, corresponds to a rotational quality factor, $Q > 3 \times 10^{19}$. After a constant slow-down rate has been removed from the timing data, we find that the measured fractional stability of the pulsar is better than one part in 10^{13} over timescales of ≥ 6 months. This remarkable long-term stability is equal to or exceeds that of the best existing atomic clocks.

There are many potentially interesting applications of a series of regular comparisons between a distant, natural standard of dynamical time and Earth-bound atomic clocks. For example, we already can place cosmologically interesting limits on a stochastic background of gravitational radiation in the Universe, by extending to higher precision the methods used recently with slower pulsars[3,4]. In addition, we can use the data to achieve sub-milliarc second astrometric accuracies relative to a coordinate system based on the motion of planets in the Solar System. Consequences of the astrometric results of this experiment will be published elsewhere[5]. Over the next few years there is good reason to expect that timing data on PSR1937+21 will help to elucidate knowledge of the Earth's motion in the Solar System, provide substantially tighter limits on the energy density of low-frequency gravitational radiation in the Universe and possibly even provide a useful new long-term standard of dynamical time.

Arrival time observations

Our observations have been made at 1,408 MHz, using the Arecibo 305-m telescope and the Princeton pulsar-timing equipment[6] developed for observations of the binary pulsar PSR1913+16. Incoming signals with both senses of circular polarization are amplified, converted to 30 MHz and introduced to a $2 \times 32 \times 0.25$ MHz filter-bank receiver. The detected outputs from the two orthogonally polarized channels at the same frequency are added, and the 32 total-power sums are sampled at ~25-μs intervals and progressively summed in a digital delay line serving as a de-disperser[7]. Output from the de-disperser is converted back to analogue form and fed to a signal averager which samples the signal every 1/64 of a period and produces an integrated pulse profile for each 2 min of observation. The sampling is accurately synchronized to the pulsar period and corrected for Doppler shifts induced by the Earth's motion. Near the middle of each 2-min integration the time corresponding to the sample stored in the first 'bin' of the accumulating waveform is automatically recorded; at the end of each integration, the timing information is saved on magnetic tape together with the observed pulsar waveform.

Approximately 60 integrations can be recorded during the time the pulsar remains in view on a given day. After the observations are complete, the phase of each 2-min integrated profile is determined by cross-correlation with a 'standard profile' formed by averaging a large number of profiles. To reduce the volume of data, we then average the observed phases in groups of 15 consecutive integrations. The mean phase is converted to seconds and added to the time recorded for the first bin at the midpoint of the eighth integration, thereby yielding an effective pulse arrival time for each 30 min of data.

Our basic observational data now consist of 196 30-min observations of pulse arrival time at the Arecibo telescope, measured in a locally kept approximation to coordinated universal time (UT). During these observations, time at Arecibo Observatory was maintained by a clock that counts the cycles of a 5-MHz signal from a Hewlett-Packard model 5641 rubidium clock. The offset between this clock and UT (kept by the United States Naval Observatory, USNO) is measured once a day by the use of Loran-C timing signals broadcast from Jupiter, Florida. (The free-running rubidium clock typically accumulates phase drifts of a few tenths of a microsecond per day.) We apply retroactive corrections to epochs of the Loran-C signals, as published by USNO, to remove drifts of the master clock in Florida relative to the more accurate master clock kept by USNO in Washington. In addition, epoch comparisons with other time standards are made occasionally by means of very long baseline interferometry observations[8] and by occasional checks with travelling clocks from USNO. We believe that our corrected timescale at Arecibo Observatory has been consistent with UT (USNO) to within 1 μs at most times.

Data analysis

Our goal in analysing the data of this experiment is to compare the pulsar 'clock' with a uniform standard of dynamical time. To this end, we convert our measured times to UT (USNO) and then to International Atomic Time (TAI) by adding a constant offset plus appropriate leap seconds. The topocentric TAI arrival times are converted to times at the Solar System barycentre by applying geometry based on interpolations of an accurate ephemeris of the Earth's motion. We also adjust the arrival times to correct for (1) dispersive delays in interstellar and

‡ To whom correspondence should be addressed.
§ Present address: Department of Physics and Astronomy, Carleton College, Northfield, Minnesota 55057, USA

interplanetary space; (2) relativistic propagation delay caused by the pulsar signal moving through the gravitational field of the Sun; (3) gravitational redshift in the rates of terrestrial clocks caused by the changing gravitational potential at Earth; and (4) varying time dilation caused by changes in the Earth's velocity. Our procedure is basically that described by Manchester and Taylor[9] and used routinely for slower pulsars[10,11]. However, the precision desired in the present experiment requires an improved model for the conversion of proper time at Washington, TAI (USNO), to coordinate time at the Solar System barycentre, or barycentric dynamical time (TDB).

Corrections applied to the observed pulse arrival times are summarized in the equation

$$t_b = t_{obs} + (\mathbf{r}\cdot\hat{\mathbf{n}})/c + \Delta t_r - \Delta t_g - D/f^2 \quad (1)$$

where t_b is the infinite-frequency coordinate time of pulse arrival at the Solar System barycentre, t_{obs} is the measured TAI of pulse arrival at the observatory, $\mathbf{r}$ is the vector displacement of the telescope from the barycentre, $\hat{\mathbf{n}}$ is a unit vector pointing from the barycentre to the pulsar, c is the speed of light, Δt_r is the relativistic correction from proper time (TAI) to coordinate time (TDB), Δt_g is the gravitational propagation delay, D is the dispersion constant and f the observing frequency, transformed to the barycentric reference frame. Note that for the convenience of terrestrial observers, our unit of time, even for quantities measured in the barycentric frame, is the A.1 second as measured by a fictitious clock moving in a circular orbit 1 AU from the Sun. (This timescale is not presently defined by any international agreement. A precise definition must also specify an interval over which the gravitational influences of the planets have been averaged, for the proper times-to-coordinate times tabulated in the PEP740-R ephemeris (J. F. Chandler *et al.*, personal communication), this interval was JED 2430000-2451545.)

In practice, we obtain the required values of $\mathbf{r}$ and Δt_r by interpolation of the Center for Astrophysics PEP740-R ephemeris, using 10-point interpolation formulae. Calculation of Δt_r by numerical integration of the planetary ephemerides is necessary to achieve the desired accuracy of 0.1 μs. (The closed-form approximation derived by Moyer[12] seems to contain errors of a few μs.) After applying all known corrections of ≥ 0.1 μs amplitude to obtain values of t_{obs} in TAI units, and then calculating t_b with the aid of equation (1), we obtain a series of barycentric arrival times t_i, $i = 0, 1, \ldots, 195$, where we have dropped the original subscript on t_b. The expected pulsar phase (in turns) corresponding to the ith arrival time is given by

$$\phi(t_i) = \phi_0 + \nu_0(t_i - t_0) + \tfrac{1}{2}\dot{\nu}(t_i - t_0)^2 \quad (2)$$

where ϕ_0, ν_0 and ν are the pulsar phase, frequency and frequency derivative, respectively at time t_0. The arrival time 'residual' (in s) is then given by

$$R(t_i) = \frac{\phi(t_i) - n(t_i)}{\nu_0} \quad (3)$$

where $n(t_i)$ is the integer closest to $\phi(t_i)$. Using standard procedures we minimize the sum-of-the-squares of all residuals, solving for corrections to ϕ_0, ν_0, $\dot{\nu}$ and the two position and two proper motion terms implicit in the unit vector $\hat{\mathbf{n}}$ in equation (1) The results of such a fit are shown in Table 1, where by convention we list the pulsar period and derivative, instead of frequency and derivative. Post-fit residuals from the solution are plotted in Fig. 1.

It is clear from Fig. 1 that the residuals are dominated by systematic effects, rather than by random measurement errors. For example, residuals from data obtained in a single day tend to be highly correlated and weaker correlations over timescales of several months are also evident. Possible causes of systematic errors that we cannot yet eliminate at the ~1 μs level include clock errors (perhaps related to the transfer of time from Washington to Arecibo), imperfect removal of dispersion from the scintillating pulsar signal, ephemeris inaccuracies and small changes in propagation time caused by interstellar gas clouds drifting across the line-of-sight[13]. Since October 1984 we have been making observations designed to identify and reduce these possible sources of error. (Time is now transferred to Arecibo Observatory by signals from satellites in the Global Positioning System, with accuracies in the tens-of-nanoseconds range. In addition, we have built a new multichannel signal averager that exactly follows the inverse frequency-squared dispersion law.)

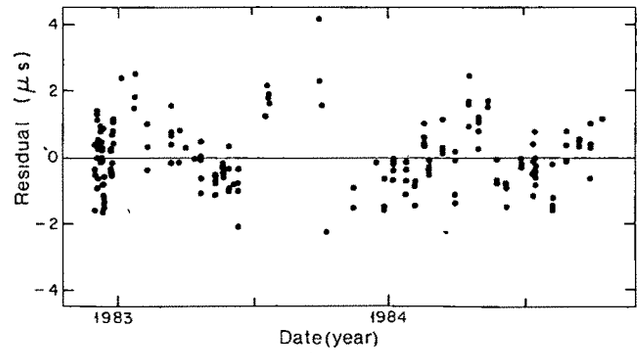

Fig. 1 Post-fit timing residuals for PSR1937+21, after a solution for period, period derivative, position and proper motion. Each circle represents a 30-min observation; the r.m.s. residual is 0.9 μs.

Table 1 Measured parameters of PSR1937+21

Period	$P = 0.0015578064488724 \pm 2$ s
Period derivative	$\dot{P} = (1.05110 \pm 0.00008) \times 10^{-19}$ s s^{-1}
Right ascension (1950.0)	$\alpha = 19$ h 37 min 28.74600 s ± 0.00003 s
Declination (1950.0)	$\delta = 21$ h 28 min 01.4606 s ± 0.0010 s
Proper motion in α	$\mu_\alpha = -0.3 \pm 0.4$ marc s yr^{-1}
Proper motion in δ	$\mu_\delta = -1.4 \pm 1.0$ marc s yr^{-1}
Epoch (at barycentre)	$t_0 = 2445303.2731658$ JED
Assumed dispersion	$D = 2.94788 \times 10^{17}$ Hz

Quoted positions are in the coordinate system of ephemeris PEP740-R.

For the 1982–84 data, however, we must conclude that the root-mean-square residual, ~0.9 μs, is dominated not by instabilities in the pulsar or by receiver noise but by systematic (possibly instrumental) effects. For this reason, we have adopted a conservative attitude toward the formal standard deviations of the parameter estimates. The uncertainties quoted in Table 1 are four times the formal standard errors from the least-squares fit, and are approximately equal to those which would be obtained if we had available one measurement of ~2 μs accuracy for each observing day. We hope to be able to relax this cautious procedure in the near future and to improve further the accuracies of the fitted parameters.

Pulsar parameters

The pulsar period and derivative listed in Table 1 are consistent with, but much more accurate than, our previously published values[2]. They confirm that the characteristic age of this pulsar is rather large, $P/2\dot{P} \approx 2 \times 10^8$ yr, and that if the slow-down torque is provided by magnetic dipole radiation, the surface magnetic field must be unusually small, $3.2 \times 10^{19} (P\dot{P})^{1/2} \approx 5 \times 10^8\, G$ (where G is the Newtonian constant) (see, for example, Chapter 9 of ref. 9). Attempts to solve for a second derivative of period yield only an upper limit, $|\ddot{P}| < 10^{-29}$ s^{-1}. This limit is not surprising because the value expected for magnetic dipole braking is $\ddot{P} = -\dot{P}^2/P \approx -7 \times 10^{-36}$ s^{-1}.

The measurement of the pulsar position in the sky described here is also consistent with previous work, but the precision of our new result is considerably higher. The uncertainties quoted in Table 1 are relative to the coordinate system implicitly defined by the PEP740-R ephemeris. The orientation of the ephemeris coordinate system relative to, say, the FK4 system, is *a priori* uncertain by ~0.2″ (J. F. Chandler *et al.*, personal communication). Recently, it has been shown that the reference frame of the PEP311 ephemeris, which is in close alignment with PEP740-R, is offset in the direction of PSR1937+21 by ~0.2″ with respect to both the Jet Propulsion Laboratory planetary ephemerides

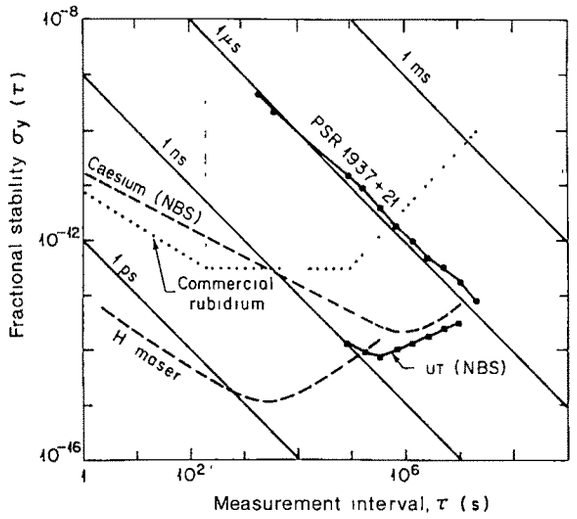

Fig. 2 Measured frequency stability $\sigma_y(\tau)$, for PSR1937+21, over intervals, τ, from 30 min to 256 days. For comparison we also plot stability curves representative of several types of atomic clocks. The curve labelled 'rubidium' refers to typical commercially available standards; those labelled 'caesium (NBS)' and UT(NBS) are based on Fig 3 of ref. 28 and the 'H maser' curve is adapted from Fig. 5 of ref. 29

and the FK4 system[14,15]. These astrometric details are of considerable interest, and will be discussed elsewhere[5].

Until we have removed all ~1-μs systematic errors from the data and acquired a better understanding of possible ephemeris errors at the same level, our solution for proper motion should be treated as an upper limit of $|\mu| \leq 3$ marc s yr^{-1}. At a distance[16] of 5 kpc, this limit corresponds to a transverse velocity ≤ 70 km s^{-1}, which is puzzling as differential galactic rotation is expected to create an apparent transverse velocity of ~100 km s^{-1}. It is possible, of course, that the pulsar's peculiar velocity happens to cancel a large portion of the transverse component of differential galactic rotation.

It is reasonable to enquire about the magnitudes of effects not included in our timing model which might influence the pulse arrival times significantly and bias some of the parameter estimates. In Table 2 we list several such possibilities, in addition to the effects that are explicitly included in the model. Our model will need further improvements if the data are to be improved by another order of magnitude.

We are aware of several other effects that may contribute significantly to the measured pulse arrival times, such as secular changes in the Doppler shifts caused by differential galactic rotation and possible changes in G. However, these effects will be stable over very long timescales, so their effect is simply to bias our estimate of the pulsar spindown rate by ~1% without contributing significantly to the post-fit arrival-time residuals.

Stability of the pulsar clock

The predictability of man-made clocks is customarily measured in terms of the fractional frequency stability $\sigma_y(\tau)$ measured over various time intervals τ. The square of $\sigma_y(\tau)$, termed the 'Allan variance,' is defined by

$$\sigma_y^2(\tau) = \frac{1}{2}\left\langle \left(\frac{R(t+\tau) - 2R(t) + R(t-\tau)}{\tau} \right)^2 \right\rangle \quad (4)$$

where $R(t)$ is the post-fit residual at time t and the angled brackets signify an average taken over all available triplets of residuals spaced by $\pm\tau$. We have computed Allan variances from the post-fit residuals to the PSR1937+21 timing data, and the results are plotted in Fig. 2. For comparison we have also plotted curves that correspond to the stabilities of typical rubidium and caesium clocks and hydrogen masers and for the bank of caesium clocks maintained by the United States National Bureau of Standards. We note that although $\dot{P}/P$ for PSR1937+21 and other fast pulsars far exceeds the fractional drift rates of atomic clocks[17], the physical process that produces $\dot{P}$ is sufficiently well understood to predict that higher-order derivatives will be much smaller for pulsars than for atomic clocks. Thus, the timescale at which the stability curve for PSR1937+21 turns upward will probably be much longer than that for the man-made clocks.

Figure 2 makes it clear that over timescales of the order of one year, radioastronomical observations of PSR1937+21 can provide a standard of time that is competitive with any other available standard. Obviously the practical attractiveness of this new basis for barycentric dynamical time will be greatly enhanced if several more millisecond pulsars are found and their timing behaviours monitored and compared.

Table 2 Contributions to observed pulse-arrival times

Cause	Model magnitude (μs)	Estimated error (μs)
Pulsar		
Spin	$3\times10^{13}\,t$	—
Spindown	$3\times10^{4}\,t^2$	—
Timing noise	—	$0.01\,t^{3/2}$
Propagation at 1.4 GHz		
Interstellar medium	1.5×10^{5}	$0.5\,t$
Interplanetary medium	0.4	<0.4
Ionosphere	—	<0.04
Troposphere	—	<0.01
Clocks and corrections		
UT(AO)-UT(JUP)	1	0.5
UT(JUP)-UT(USNO)	1	0.2
UT(USNO)-TAI(USNO)	50	0.0
Errors in TAI(USNG)	—	$0.3\,t$
Reduction to barycentre		
Observatory to centre of Earth	2×10^{4}	0.01
Earth to barycentre	4×10^{8}	$0.6\,t$
TAI-TDB	1,600	0.1
Gravitational propagation delay	20	<0.1
Parallax of pulsar	—	0.06

For each of the named contributions to pulse arrival time, the left-hand column gives an indication of the magnitude of the effect currently included in the model and the right-hand column gives our estimate of the errors caused by having ignored it or having modelled it imperfectly. Times, t, are measured in years. AO stands for Arecibo Observatory and JUP for the Loran station at Jupiter, Florida.

Gravitational radiation

According to some cosmological models, a substantial fraction of the energy density, ρ_c, required to close the Universe might be expected in the form of very low-frequency gravitational radiation[18-21]. Specific mechanisms that have been proposed include the transition of the Universe from a de Sitter inflationary phase to a radiation-dominated era[22], oscillating cosmic strings[23,24], a quantum chromodynamic phase transition in the early Universe[25] and other exotica. Clearly, the eventual measurement of a cosmic background of gravitational radiation and the determination of its spectrum could play an important role in understanding the early Universe.

At some level, the apparent stability of any distant clock sending its 'ticks' to Earth by electromagnetic signals must be limited by perturbations in the spacetime metric between the clock and Earth. This fact is the basis for using pulsar timing data or spacecraft-tracking data to place limits on the energy density of a cosmic background of gravitational radiation[26]. The basic argument is that a plane gravitational wave of dimensionless amplitude h and period τ carries energy density

$$\rho = \frac{1}{8\pi G}\left(\frac{2\pi}{\tau}\right)^2 h^2 \quad (5)$$

Such a wave would produce pulsar timing perturbations of size $\delta t \approx h\tau$ which, if large enough, would dominate the residuals in the timing data. The longest period τ that will contribute significantly to the residuals is roughly half the time span of the observations. Thus, our two years of timing data with r.m.s. residual $\delta t = 0.9\ \mu s$ would seem to place an upper limit of $h \lesssim \delta t/\tau = 3\times10^{-14}$, or $\rho \lesssim 2\times10^{-35}\ g\ cm^{-3}$, for a stochastic background of gravitational waves of period ~1 year. This limit is substantially below the cosmological critical density $\rho_c = 3H_0^2/(8\pi G) = 2\times10^{-29}\ g\ cm^{-3}$ for a Hubble constant $H_0 = 100\ km\ s^{-1}\ Mpc^{-1}$.

A more rigorous treatment of the limits that can be placed on a cosmic background of gravitational radiation from pulsar-timing data has been given by Blandford *et al.*[27]. Their method makes quantitative allowance for the fraction of timing noise power that is absorbed into fits for the parameters of Table 1, and more accurately assesses the varying sensitivity of the method to gravitational waves of different frequencies. Their result can be summarized in the equation

$$\Omega_g(f) = 7.4\times10^{-5}\,(s-1)\,(\beta/N)^{(s-1)}\,H_{100}^2\,\delta t_{\mu s}^2 \qquad (6)$$

where $\Omega_g(f)$ is the ratio of gravitational wave energy density (per natural logarithm frequency interval at frequency $f \approx \beta/N$) to the cosmological critical density ρ_c, s is the power law spectral slope expected for the timing residuals due to gravitational waves, N is the length of the data span in years, β is a parameter characterizing the effective low-frequency cutoff in the sensitivity to gravitational waves, H_{100} is the Hubble constant in units of $100\ km\ s^{-1}\ Mpc^{-1}$ and $\delta t_{\mu s}$ is the post-fit r.m.s. timing residual in microseconds. For cosmologically interesting mechanisms of generating gravitational waves, s is expected to lie in the range 5–7, and for $N = 2$ Blandford *et al.*[27] find that $\beta = 2.05$. Thus, for $H_{100} = 1$ we can now place the very firm limit $\Omega_g < 5\times10^{-4}$ for a stochastic background of gravitational waves in the frequency range ~1–3 cycles $year^{-1}$. This limit is not yet sufficient to constrain models which use primordial cosmic strings as an aid to galaxy formation[24]. However, the limit on Ω_g at the lowest accessible frequencies varies approximately as $\delta t_{\mu s}^2/N^4$, so that if: (1) the apparent pulsar stability remains high; (2) instrumental improvements can reduce the contributions of random noise and systematic errors to δt; and (3) the duration of observations N can be significantly extended, another two or even three orders of magnitude are potentially within reach.

We thank S. Kulkarni and L. Rawley for assistance with some of the observations, J Chandler for sending us the PEP740-R ephemeris and related software and R Blandford, R. Hellings and E. Witten for stimulating discussions. The National Astronomy and Ionosphere Center is operated by Cornell University under contract with the NSF.

Fused transcript of *abl* and *bcr* genes in chronic myelogenous leukaemia

Emma Shtivelman, Batia Lifshitz, Robert P. Gale* & Eli Canaani

Department of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel

Human chronic myelogenous leukaemia is characterized by a reciprocal translocation between chromosomes 9 and 22 resulting in an abbreviated form of chromosome 22 and the transfer of the abl *cellular oncogene from chromosome 9 into the* bcr *gene of chromosome 22. Characterization of an 8-kilobase RNA specific to chronic myelogenous leukaemia shows it to be a fused transcript of the two genes. The fused protein that would be produced is probably involved in the malignant process.*

CHRONIC myelogenous leukaemia (CML) is characterized by the proliferation and accumulation of myeloid cells and their precursors[1] and is clinically divided into two phases. The initial chronic phase lasts for three to four years and the primary abnormality is a marked increase in the stem-cell compartment committed to myelopoiesis. This is followed by the acute phase (blast crisis) of 3–6 months' duration and characterized by a decrease in the differentiation ability of the cells and the loss of response to regulatory factors. In some patients there is a transitional accelerated phase.

Most (90–95%) CML patients carry in their myeloid cells a unique chromosomal aberration—a shortened chromosome 22 termed the Philadelphia (Ph^1) chromosome[2–6]. The origin of Ph^1 was identified as a reciprocal translocation between chromosomes 22 and 9, referred to as t(9; 22) (ref. 7). The localization of the cellular oncogenes *abl* and *sis* close to or at the breakpoints on chromosomes 9 and 22, respectively[8–10], and the finding that the oncogenes are included in the exchanged segments of these chromosomes[11,12] suggest that one or both are involved in development of CML. Subsequent studies failed to detect *sis* transcription in CML[13], indicating that this oncogene does not play a role in the disease.

Mapping of the breakpoints on chromosome 9 indicated variable distances 5′ (upstream) of the first known exon of *abl*. In one individual the breakpoint was 14 kilobases (kb) 5′ of the oncogene, and in others it occurred further upstream and has

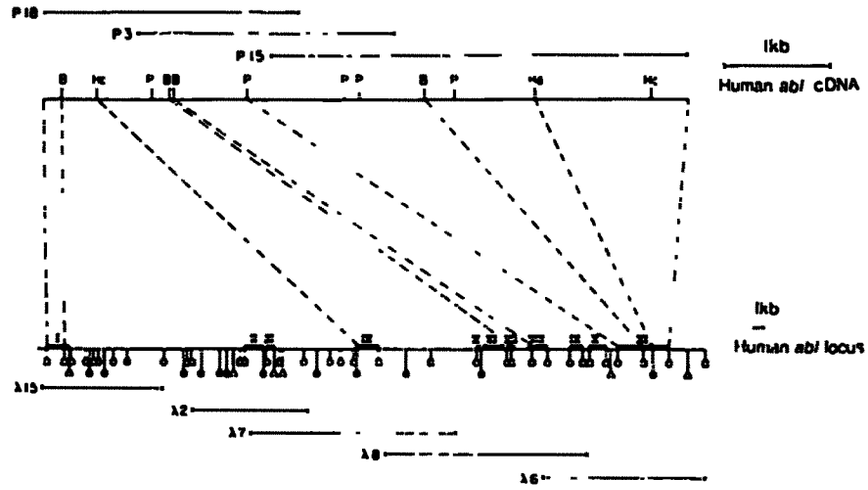

Fig. 1 Physical maps of normal human *abl* cDNA and locus. Restriction enzymes sites on cDNA are of *Bgl*II (B), *Hin*cII (Hc), *Pst*I (P), *Hin*dIII (Hd) Sites on locus are *Bam*HI (Δ), *Bgl*II (□), *Hin*dIII (●), *Eco*RI (○) Exons within the genomic DNA were determined by hybridization of radiolabelled cDNA fragments to fragments of the cloned genomic DNA Exons are depicted as dark boxes delineated between restriction sites bordering the hybridizable fragments With the exception of exon XI the size of the boxes does not reflect the length of the corresponding exons
Methods. Analysis of cDNA was performed on the three overlapping phage clones P18, P3 and P15. A cDNA library was constructed[29] with poly(A) RNA isolated from the SV80 cell line[28] An 8-μg sample was treated with 1 mM methylmercury for 10 min at room temperature, neutralized with 10 mM mercaptoethanol and alcohol-precipitated. The cDNA was made according to published procedures[29-31] the first strand was synthesized with reverse transcriptase using oligo(dT) as a primer and the second strand synthesized with a combination of the enzymes PolI, RNase H and DNA ligase. Following 'filling in' in Klenow fragment[32], the cDNA was treated with *Eco*RI methylase and ligated to *Eco*RI linkers Excess linkers were removed by selective precipitation for 20 min at room temperature in 2 M ammonium acetate with an equal volume of isopropanol, followed by agarose electrophoresis, electroelution and absorption and elution from Elutip d-Columns. From a total of 200 ng cDNA obtained, 50 ng were used and cloned in λgt10 vector[20] to yield ~200,000 recombinant plaques Following amplification, the library was screened with a v *abl*-specific probe[33] and nine positive plaques were detected, purified and analysed The locus was cloned by partially digesting normal genomic DNA with *Mbo*I, selecting fragments of 10-20 kb and cloning it into the *Bam*HI site of λL47 vector[23] Phages containing *abl* sequences were detected using the cDNA as a probe Sites in the 2 kb gap between λ15 and λ2 are from ref 14. Southern blot analysis of human DNA showed no hybridization to *abl* cDNA probe of fragments spanning the gap

not yet been accurately mapped[14]. The situation on chromosome 22 is different; the breakpoints in diffeent CMLs occurred in a restricted region of ~5.8 kb. This region was termed the breakpoint cluster region or *bcr* (ref. 15), and its consistent rearrangement in CML patients strongly implicates it in the pathogenesis of CML.

Studies of *abl* transcription provided the first strong evidence for involvement of the oncogene in CML A novel 8-kb *abl* RNA larger than the normal species of 6 and 7 kb has been identified in the leukaemic cells of essentially all CML patients and cell lines containing Ph^1 (refs 13, 16, 17). This RNA was found both in bone marrow and peripheral blood of patients in chronic phase or blast crisis. Finally, analysis of the Ph^1-positive K562 cell line identified a new *abl* protein of relative molecular mass (M_r) 210,000, larger than the normal human species of M_r 145,000 (refs 18, 19). Unlike the normal species, the larger protein has a tyrosine kinase activity, which is a common feature of retroviral transforming proteins. By cloning and characterizing complementary DNA of the normal and CML-specific *abl* RNA, we show here the latter is a hybrid molecule containing *bcr* and *abl* sequences. Nucleotide sequencing analysis indicates that the protein translated from the fused RNA has *bcr* information at its amino terminus and that it retains most but not all of the normal *abl* protein sequence

Cloning of normal *abl* cDNA

The direct approach to study the relationship between normal human 6- and 7-kb *abl* transcripts and the altered CML cell-specific 8-kb species is to obtain cDNA copies of the transcripts and compare them by restriction enzyme mapping. To obtain normal *abl* cDNA, RNA from the simian virus 80 (SV80) human fibroblast cell line was used to construct a cDNA library in the λgt10 vector[20]. The library was screened with a radiolabelled probe specific for v-*abl*, the Abelson virus homologue of the mouse *abl* gene[21] Nine positive plaques (out of 200,000 screened) were detected, then purified and analysed. The physical map of cDNA based on three overlapping clones is shown in Fig. 1 (upper part) The cDNA is 6 kb long and ends with a stretch of poly(A) at the 3' end (B. Roe *et al.*, in preparation). It extends 520 nucleotides 5' of the beginning of v-*abl* (ref. 22) positioned eight nucleotides left of the *Hin*cII site present in clone P18. A long open reading frame begins at the 5' end of the cDNA and extends into the region homologous to v-*abl* An ATG identified 150 nucleotides downstream of the cDNA 5' terminus (Fig. 3; B. Roe *et al.*, in preparation) might serve as a translational initiation codon. It is not yet known whether normal human *abl* RNA contains additional sequences at its 5' end which are not included in our cDNA

The cDNA was used as a probe to clone the *abl* locus. A partial *Mbo*I digest was prepared from white blood cells of a normal individual and, after size fractionation into 10-20-kb fragments, was cloned into the *Bam*HI site of λL47 vector[23]. A region of >50 kb was cloned in five overlapping phages and mapped with restriction enzymes (Fig. 1, bottom). The relationship between *abl* cDNA and locus was determined by hybridizing segments of the former to fragments of the latter (Fig. 1). Hence it was possible to identify 11 exons in the locus, 4 of which (I, II, IV, VI) were not detected or distinguished from other exons from a previous analysis where v-*abl* was used as a probe[14]. Sequences spanning the 3' two-thirds of the cDNA (delineated between a *Pst*I site and the 3' terminus) are apparently all included in a single exon, XI. The distribution of exons in the mouse *abl* locus[24] has common features with the situation described here for the human *abl* locus.

Cloning and sequencing of *abl* cDNA

To clone cDNA derived from the CML-specific 8-kb *abl* RNA, we used RNA extracted from the cell lines K562 and EM2. In both lines the predominant *abl* RNA is the 8-kb species (ref 13, Fig. 4). cDNA libraries were constructed in λgt 10 vector and screened with a radiolabelled probe prepared from the 0.9-kb *Bgl*II fragment located at the 5' region of normal *abl* cDNA (Fig. 1) About 30 positive plaques of 1×10^6 screened were detected in each library; all were purified and examined by digestion with restriction enzymes.

The physical maps of two clones from each library were compared with normal *abl* cDNA (Fig. 2). Clone E6 has an identical map compared with the corresponding region on the normal cDNA, whereas clones E3, K28 & K30 share most restriction enzyme sites with the normal *abl* cDNA, but vary from the latter at the 5' region. Thus, a constellation of sites for *Ava*I, *Bgl*II and *Pvu*II enzymes present at the left end of the normal cDNA is missing from the three clones and is replaced in E3 and K28 with *Pst*I and *Hin*dIII sites.

To analyse further the variance between normal *abl* cDNA and K562 and EM2 cDNAs, we sequenced the 5' regions of

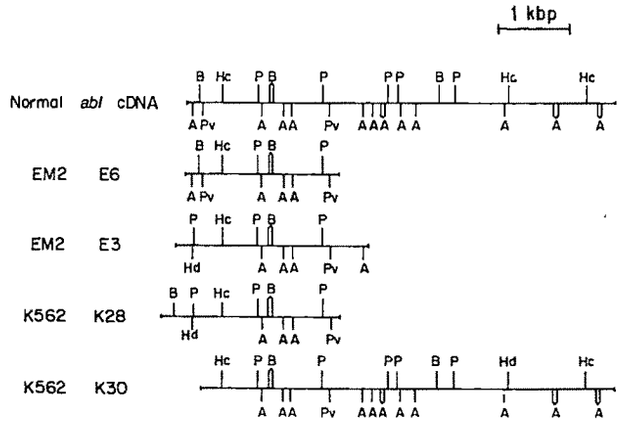

Fig. 2 Comparison between maps of normal *abl* cDNA and of *abl* cDNAs synthesized on RNA from the Ph[1]-positive K562 and EM2 cell lines. Restriction enzymes used included *Ava*I (A), *Bgl*II (B), *Pvu*II (Pv), *Hin*cII (Hc), *Pst*I (P) and *Hin*dIII (Hd).

these species (in clones P18, K28 and E3). The nucleotide sequences are depicted in Fig. 3 along with the sequence[24] of a mouse *abl* exon for comparison. The normal *abl* cDNA sequence is composed of an open reading frame extending into the region homologous to v-*abl*. K562 and EM2 have an identical sequence that diverges from the corresponding normal species in nucleotide 1. The sequence 3′ to this point is shared by the three cDNAs, whereas 5′ to this position the normal cDNA sequence is substituted in K562 and EM2 cDNAs with a new sequence. The inserted new DNA fragment is composed of an open reading frame that joins in phase the rest of *abl* open reading frame.

Characterization of new sequence

The finding of a new DNA linked to *abl* cDNA and substituting a portion of the coding region of the latter in CML cells suggested that the CML-specific 8-kb *abl* RNA originates from this linkage. To test this directly we subcloned into the puc13 plasmid the 0.45-kb *Eco*RI/*Pst*I fragment located at the 5′ end of clone K28 (this fragment is composed entirely of non-*abl* sequences), radiolabelled it and examined its hybridization to RNAs from non-CML and CML cell lines. As a control, the blot was first hybridized to the v-*abl* probe and was found to show the normal 6- and 7-kb *abl* RNAs in all lines and the 8-kb *abl* RNA in K562 cells (Fig. 4*A*). The *Eco*RI/PstI fragment reacted with the 8-kb species but not with normal *abl* RNAs (Fig. 4*B*). Two additional transcripts of ~4.5 and ~6.7 kb were apparent in all lines, in particular in SMS-SB. We conclude that cDNA clones E3, K28 and K30 originate from the 8-kb altered *abl* transcript and that the non-*abl* sequence contained in this RNA is also expressed in other human cell lines in the form of two distinct transcripts of 4.5 and 6.7 kb.

To study further the nature of the new sequence we used the *Eco*RI/*Pst*I-radiolabelled fragment to probe Southern blots of normal DNA digested with *Eco*RI, *Bam*HI and *Hin*dIII, and we detected single fragments of 17, 12 and 11 kb, respectively (not shown). The 17-kb *Eco*RI fragment was cloned into λ Charon 4A vector[25] and mapped with restriction enzymes (Fig. 5*A*). Examination of the map of our clone revealed that it is very similar to the physical map of the breakpoint cluster region (*bcr*) reported previously by others[15]. As the hallmark of this region[15], located on chromosome 22, is that it is cleaved in all Ph[1]-positive CMLs (so that sequences 5′ to the breakpoint remain on chromosome 22 and sequences 3′ to this site translocate to chromosome 9), we tested whether our *Eco*RI/*Pst*I DNA probe would detect such breaks. DNAs from leukaemic cells of eight CML patients were cleaved with *Sst*I enzyme, electrophoresed on agarose gel, blotted onto nitrocellulose filter and hybridized to our probe. Six of eight samples showed a new fragment not detected in the normal control. Part of this analysis is shown in Fig. 5*B*. We conclude that the new sequence linked

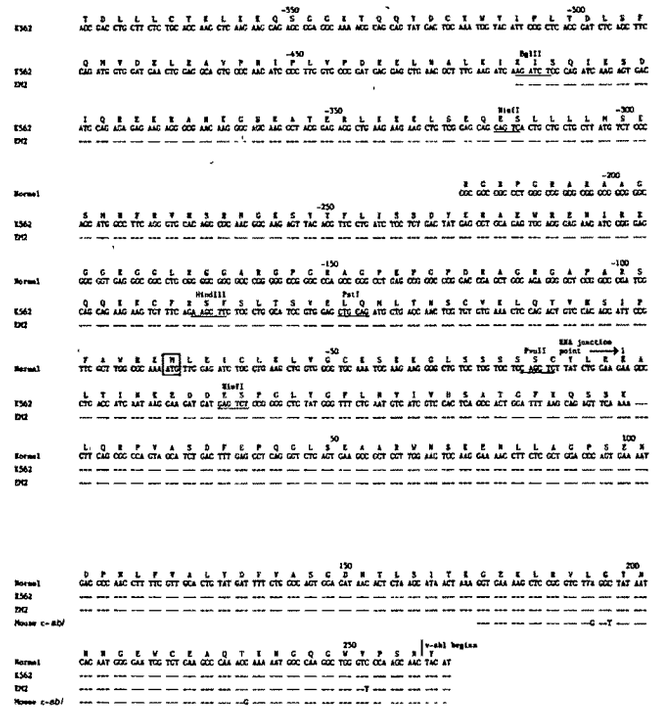

Fig. 3 Nucleotide sequence of the region of divergence between normal, K562 and EM2 *abl* cDNAs. Regions delineated between the 5′ terminus and the *Hin*cII site in clones p18 (normal), E3 (EM2) and K28 ((K562) were sequenced on both strands by the Maxam and Gilbert technique[34]. The sequence numbers are from the point of divergence between the normal *abl* cDNA and the two other species. Dashes represent the same nucleotides as in the line above; single letters above the sequence correspond to amino acids translated from the sequence; boxed ATG at position −79 on the normal cDNA could be the initiation codon for normal *abl* protein. Alternatively, initiation is in as yet uncloned sequence 5′ to the beginning of clone p18. A portion of mouse *abl* sequence[24] is shown for comparison.

to *abl* cDNA (RNA) in K562 and EM2 lines is derived from the *bcr* and that CML-specific 8-kb RNA is a fused transcript of *abl* and *bcr*.

After cloning *abl* and *bcr* loci, we were able to map the sequences at the RNA junction point to their coding regions in the loci. This was done by isolating the *Hin*fI/*Hin*cII fragment from the K28 clone and using it as a radiolabelled probe. The fragment spans the cDNA linkage point and contains 65 and 258 base pairs of *bcr* and *abl* information, respectively (Fig. 6). The probe was annealed to a *Bgl*II + *Hin*dIII digest of the DNA of phage λ2 containing exons II and III of the *abl* locus (Fig. 1). A 2-kb fragment containing exon II and a 1.1-kb fragment containing exon III reacted with the probe (Fig. 6*b*). This probe did not hybridize (Fig. 6*a*) to DNA of phage λ15 that encloses *abl* exon I. These results show that *abl* RNA at the junction point is transcribed from exon II and that sequences of exon I are not included in the 8-kb transcript. Hybridization of the same probe to different segments of *bcr* showed a reaction (Fig. 6*c*) with a 1.3-kb *Bam*HI/*Hin*dIII DNA at 15–16.3 kb on the *bcr* map (Fig. 5*a*). Thus, a sequence transcribed from this area forms the RNA junction point.

Conclusions

The results described here help to explain previous observations that implicated the *abl* oncogene and *bcr* in the pathogenesis of CML. The CML-specific 8-kb RNA is a hybrid transcript of *abl* and *bcr* genes. As a result of the t(9; 22) translocation both genes are juxtapositioned on Ph[1], conceivably in a head-to-tail configuration with the *bcr* closer to the centrometer[15]. The 8-kb transcript presumably initiates in the *bcr* and extends into *abl* sequences by a splicing mechanism. The great variance in the distance between the chromosomal breakpoints and *abl*[14]

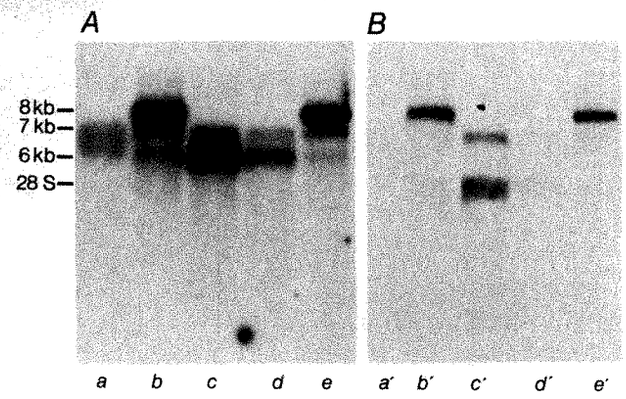

Fig. 4 Hybridization to human RNA of the sequence linked to *abl* RNA in K562 and EM2 cell lines. The blot was first hybridized to v-*abl* probe (*A*), then 'stripped' by washing in methyl mercury hydroxide and rehybridized (*B*) to the 0.45-kb *Eco*RI/*Pst*I fragment from the 5′ terminus of clone 28. 10-μg aliquots of poly(A) RNA from the cell lines K562 (*b*, *e*), HL-60 (*a*), SMS-SB (*c*) and Molt 4 (*d*) were electrophoresed, blotted onto nitrocellulose filter and hybridized as described[13].

(although the breakpoints are presumed always to be positioned 5′ of the main body of the gene) is not reflected in the size of the hybrid transcript which seems to be identical or very similar in different CMLs[13]. The RNA linkage point in respect to *abl* sequences is either at the border between exon I and II or within exon II of *abl*. This means that although the region containing exon I is included in the Ph[1] of many CMLs[15], this exon is spliced out and not included in the fused transcript of K562 and EM2 RNA and possibly in all CMLs. The *bcr* RNA at the junction point is included in an exon coded by the region at 15–16.3 kb on the *bcr* map (Fig. 5). Thus, if the RNA junction point is identical in all CMLs, this exon always has to be included in the Ph[1] and the chromosomal breakpoints must map to the right-hand side of the *Bam*HI site at 15 kb on the *bcr* map. As the breakpoints in some CMLs[15] were tentatively mapped to positions left of this *Bam*HI site, the question of whether all CMLs have identical RNA junction points must await further investigation. Nevertheless, our results suggest that CMLs will have long primary *abl*/*bcr* fused transcripts differing in size according to the distance between *abl* and the breakpoint on chromosome 9 in a particular CML. These transcripts will be spliced into identical or similar sized mature RNAs. The splice between the exon at 15 kb on the *bcr* map and *abl* exon II could involve dozens of kilobases in some CMLs. In these cases the hybrid gene on the Ph[1] would resemble in its large size the bithorax complex of *Drosophila*[26].

The 8-kb RNA in CML cells will contain ~5.7 kb *abl* information. The rest of the sequence is presumably derived from the 4.5- or 6.7-kb normal *bcr* transcripts identified here. Comparison of the *bcr* sequence at the junction point (Fig. 3) with a cDNA sequence of the normal *bcr* RNA[27] indicates that it coincides at a position ~1,500 nucleotides from the 3′ end of the latter. This suggests that the fusion partner in 8-kb RNA will be the 4.5-kb *bcr* RNA and that its 5′ 3 kb are joined to the 3′ 5.7 kb of *abl* to form a 8.7-kb species.

Comparison of the signal intensity of the 8-kb altered RNA and 4.5-kb normal *bcr* transcript in hybridizations using the *bcr* probe (Fig. 4) show the former to be considerably stronger (with the exception of the SMS-SB line). If, as suggested here, both transcripts initiate at the same chromosomal region, it seems that *bcr* RNA initiated on the Ph[1] (and giving rise to the 8-kb transcript) is more abundant than the 4.5- (and 6.7) kb species initiated on normal chromosome 22. Therefore, it is possible that an additional consequence of the t(9; 22) aberration is the enhanced transcription of the *bcr* positioned on Ph[1].

Fusion of the reading frames of both genes in phase will result in the translation of the 8-kb RNA into a hybrid protein. The amino terminus of the normal *abl* protein (26 amino acids if initiation of the normal protein is at the ATG in position −79

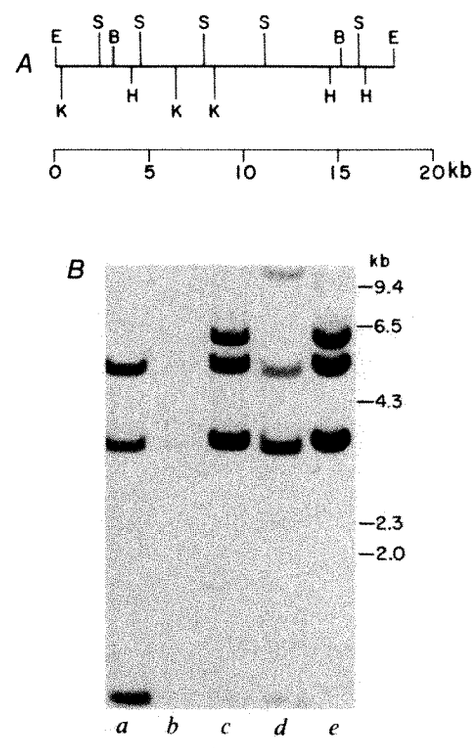

Fig. 5 Sequence linked to *abl* RNA in K562 and EM2 lines is transcribed from the *bcr*. *A*, Physical map of a genomic *Eco*RI fragment cloned from normal (SV80) DNA using the *Eco*RI/*Pst*I probe described in the text. Sites shown are of *Eco*RI (E), *Bam*HI (B), *Kpn*I (K), *Hin*dIII (H), *Sst*I (S). *B*, Hybridization of the same probe to *Sst*I digests of genomic DNAs (30 μg) from normal (*a*) and CMLs (*b*–*e*). Blots were electrophoresed and blotted by standard procedures. An 0.9-kb fragment detected at the bottom of the blot cannot be accounted for in the physical map of SV80 *bcr*, but it could result from the absence of an *Sst*I polymorphic site in SV80 *bcr*.

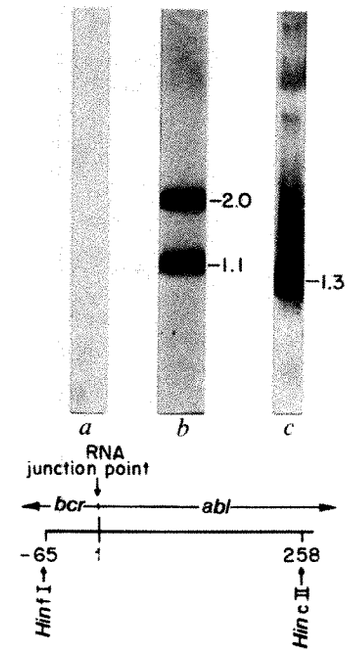

Fig. 6 Localization of sequences at the 8-kb RNA junction point on *abl* and *bcr* loci. The 0.32-kb *Hin*fI/*Hin*cII fragment from the 5′ region of clone K28 (shown at the bottom) was used as a probe in hybridization with a *Bgl*II/*Hin*dIII digest of the λ15 *abl* (lane *a*) and λ2 *abl* clones (lane *b*) shown in Fig. 1. The same probe was hybridized to a *Hin*dIII + *Bam*HI digest (lane *c*) of the genomic *bcr* clone shown in Fig. 5.

in Fig. 3, or a larger polypeptide if initiation is 5′ to this position in as yet uncloned sequence) is substituted with a *bcr* encoded polypeptide. Presumably, this protein corresponds to the M_r 210,000 *abl* protein identified in K562 cells[18,19]. The protein, unlike its normal homologue, has a tyrosine kinase activity. The substitution of the amino terminus could change the conformation of the enzyme to trigger (perhaps constitutively) the phosphorylating activity. The new amino terminus could also change the localization of the enzyme in the cell.

CML provides the first example for a human cancer where a chromosomal translocation results in the production of a modified oncogene-encoded protein which is probably directly involved with the malignant process.

We thank Drs David Wolf and Verda Rotter for the normal human cDNA library and for suggestions regarding cDNA cloning, and Professor N. Haran-Ghera and Dr D. Canaani for encouragmenet and advice. This work was supported by grants from the Edith C. Blum Foundation, National Council for Research and Development (Israel) and DKFZ (Heidelberg, FRG) and the Leo and Julia Forchheimer Center for Molecular Genetics at The Weizmann Institute of Science. E.C. is a recipient of a career development award from the Israel Cancer Research Fund and holds the Harry Kay professional chair in Cancer Research.

Note added in proof: Sequence at the RNA junction point is derived from the 3′ end of a 78-bp *bcr* exon and the 5′ end of the 174-bp *abl* exon II. Therefore, the normal splice signals of the two genes are used to form the hybrid transcript.

EXOSAT observations of a 2,000-s intensity dip in Seyfert galaxy NGC4151

D. R. Whitehouse & A. M. Cruise

Mullard Space Science Laboratory, University College London, Holmbury St Mary, Dorking, Surrey RH5 6NT, UK

Variations in the flux from active galactic nuclei (AGN) allow the testing of models of their emission mechanisms. Various suggestions for the energy generation in AGNs require the existence of a compact object, with X rays generated deep in that object's potential well and, therefore, X-ray luminosity related directly to the object responsible for their enormous luminosities. During a 5-h X-ray observation of NGC4151 we observed a significant drop in intensity lasting ~2,000 s. The event is similar to a short flux decline previously observed[1] in NGC6814. Simultaneous intensity monitoring of a quasar with coordinates close to those of NGC4151 revealed no variability in its flux, allowing instrumental causes of the event to be discounted. The short timescale of the intensity dip imposes limits of $2\times10^7\,M_\odot \leqslant M \leqslant 3\times10^8\,M_\odot$ on the mass of the central black hole. We suggest here that the sudden drop in intensity may have been caused by a change in the ionization state of gas clouds surrounding the black hole or, possibly, by the passage of a star across the line-of-sight in the dense nuclear region of the galaxy.

Fourteen extragalactic objects have exhibited variability on timescales $<10^4$ s (ref. 2 and refs therein) comparable with the light travel time across the Schwarzschild radius of a galactic nucleus-sized black hole. But in some of the X-ray observations it has been difficult to discount instrumental causes for the variability. NGC4151, one of the closest Seyfert galaxies, has been intensively studied at X-ray wavelengths[3-5], with a 2-10 keV luminosity of a few $\times10^{42}$ erg s^{-1}, a variable low-energy absorption[6,7] as well as a low-energy excess being reported[8]. Luminosity variations on timescales of days are common[9] and there has been some evidence of more rapid changes but at low statistical significance[10].

The present observations were made on 11 July 1983 with the low-energy imaging telescopes on EXOSAT (ref. 11). The detector used was a channel multiplier array (CMA) with the thin lexan filter giving a sensitivity to X rays between 0.04 and 2.0 keV. No spectral resolution was available. NGC4151 was offset from the centre of the field-of-view by ~10 arc min. The BL Lac object 1E1207.9+3945 (ref. 12) ($z=0.59$) was also observed in the field of view ~4.7 arc min from the Seyfert galaxy. Spatial filters were used to isolate the signals from NGC4151 and 1E1207.9+3945. As the filters were fixed in spacecraft coordinates throughout the observation and defined precisely the relevant areas of sky, they exclude the possibility of all but the most contrived instrumental causes of variability. The average count rate from NGC4151 was 0.022 ± 0.005 c.p.s. and that from 1E1207.9+3945 was 0.010 ± 0.005 c.p.s. The background estimates for both the Seyfert and the BL Lac object were selected from annuli of equal area and concentric to the circular area of 1 arc min radius centred on the objects chosen (the CMA FWHM response is 18 arc). Typical background count rates were a few $\times0.001$ c.p.s. Data obtained with the other low-energy imaging telescope were contaminated with solar-flare emission and cannot be satisfactorily analysed (the reason for the difference in the response of the two telescopes to solar flares is well understood). At the time of the observation reported, the medium-energy detectors were not operating in a mode which allows the comparison of their data with that from the CMAs. NGC4151 was detected in the higher energy gas scintillation proportional counter (GSPC) detector though at such a weak level as to preclude a search for variability in its count rate.

A search was conducted for variability in the flux from NGC4151 by binning the data with bin widths from 1,000 to 9,500 s in steps of 100 s and testing the value of χ^2 against the hypothesis of a uniform counting rate. Such a series of timelines do not represent completely independent trials and the interpretation of the χ^2 results must allow for this. The timelines may be considered independent if the phase difference between the last bins in each data set is greater than one bin width[13]. There were six independent timelines and the probability of obtaining the six values of χ^2 by chance in non-ordered samples was

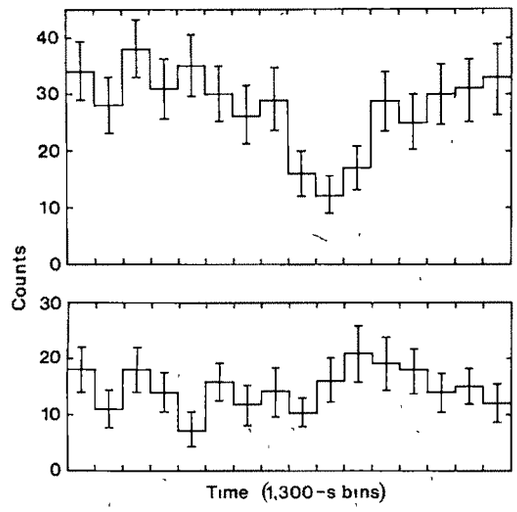

Fig. 1 The background subtracted light curves for NGC4151 (top) and IE1207.9+3945 (bottom) Origin in each case is 7 h 3 min 6 s. Times are in UT.

$<10^{-4}$. The light curves for the observation (Fig. 1) show that the cause of the large χ^2 is a decline in the flux from NGC4151 over a ~2,000-s period.

There are two plausible explanations for this intensity change. Either the opacity of the line-of-sight material within NGC4151 varied, perhaps because of changes in its ionization state, or an essentially opaque body passed between the X-ray source and the telescope. In either case, it is difficult to avoid the conclusion that both the X-ray source and the variable part of the intervening matter have dimensions of the order of, or less than, 2,000 $c = 6 \times 10^{13}$ cm.

Halpern[14] has suggested that variable absorption in QSO MR2251−178 results from changes in the ionization state of the gas surrounding the nucleus. If this model is applied to the current observations, the radial extent of the gas must be $<6 \times 10^{13}$ cm and the ionization parameter[15] ξ must lie between 1 and 100 in order for substantial changes in X-ray transmission to occur. The timescales quoted by Halpern for opacity changes are similar to the timescale of the variability reported here. The low-energy count rate requires a column density $<10^{23}$ atoms cm^{-2}. Using the extreme values allowed by the data, the electron number density in the ionized region must be $\sim 10^9$ cm^{-3}. This places the absorption cloud at 10^{15}–10^{16} cm from the nucleus to achieve the required range of ξ.

The bolometric luminosity of NGC4151, 2.7×10^{45} erg s^{-1} (ref. 2) and the observed variability enable limits to be placed on the mass of the central black hole of $2 \times 10^7 M_\odot \leq M \leq 3 \times 10^8 M_\odot$, model-dependent arguments reduce the range further. The Elliot–Shapiro relationship[16] is satisfied in this case indicating that beaming of the radiation is not required, but the Cavallo–Rees accretion scattering limit[17] is not valid for an occulting object external to the accreting material.

Stars have photospheric radii in the range 5×10^{10}–7×10^{13} cm (ref. 18) and are large enough to occult all, or a large fraction of, the X-ray emitting part of an accretion disk surrounding a black hole with mass in the range 3×10^4–2×10^8 $M_\odot$. The spatial density of stars close to the central objects may be of the order of 10^6 $M_\odot$ pc^{-3} (ref. 19) and therefore such occultations can occur on timescales of months or years. If this is so then the velocity of the occulting object must lie between 4×10^7 and 3×10^{10} cm s^{-1} to perform the occultation in the observed time. This range is appropriate for keplerian velocities within a parsec of the nucleus. We suggest that luminosity dips caused by 'star shadows' will occur, and should be searched for, regardless of whether they caused this event.

A model of object Geminga as a degenerate white dwarf orbiting around a black hole

G. S. Bisnovatyi-Kogan

Space Research Institute, USSR Academy of Sciences, 117810 Moscow, USSR

Geminga (2CG195+04) is a very bright γ-ray source with the flux $F_\gamma = 2.4 \times 10^{-9}$ erg s^{-1} cm^{-2} for $E \geq 50$ MeV (refs 1–3). It has been recently identified with X-ray[4] and optical[5] sources. The optical object is the bluest for its magnitude[5], indicating compactness of the emitting region. The high ratios $L/L_X \approx 10^3$, $L_X/L_{opt} \approx 200$ and the absence of radio emission are very unusual. The observed periodicity is $P \approx 1$ min and it changes at a rate corresponding to a doubling time of about several hundred years. I propose here a model which quantitatively explains the values of P and $\dot{P}$. It consists of a degenerate dwarf ($M_d = 0.6\ M_\odot$) filling its Roche lobe and orbiting a black hole ($M_{bh} = 4.4\ M_\odot$) with a period $P = 1$ min. Gravitational radiation dissipates the angular momentum, which leads to mass transfer with a current rate $\sim 10^{-3}\ M_\odot\ yr^{-1}$ and a period change $\dot{P}$ which agrees with the observed value. At a distance of 100 pc the flux of this radiation would be $\sim 5 \times 10^{-3}$ erg s^{-1} cm^{-2} (at $\nu = 1/30$ Hz). This is about seven orders of magnitude greater than from any other known stationary source.

Let R_{12} be the distance between the dwarf and the black hole. Because the dwarf fills its Roche lobe, its radius equals[6]:

$$R_{Roche} = R_d = R_{12} \frac{2}{3^{4/3}} \left(\frac{M_d}{M}\right)^{1/3}, \qquad M = M_d + M_{bh} \tag{1}$$

We can use this and Kepler's laws to describe the orbital period of the system

$$P = \frac{2\pi R_{12}^{3/2}}{(GM)^{1/2}} = \frac{9\pi R_d^{3/2}}{(2GM_d)^{1/2}} \tag{2}$$

On the other hand, for a dwarf made of helium or heavy elements ($\mu_e \cong 2$) the radius R_d depends on the mass M_d through the relation[7]:

$$R_d \approx 7.6 \times 10^8 \left(\frac{M_\odot}{M_d}\right)^{1/3} \text{cm} \qquad \text{for } 0.2 \leq \frac{M_d}{M_\odot} \leq 0.75 \tag{3}$$

Therefore, we can eliminate R_d from equation (2) and write the orbital period P as a function of the mass of the dwarf only

$$P = 36 \left(\frac{M_\odot}{M_d}\right) \text{s} \tag{4}$$

For $P = 60$ s the corresponding value of M_d is 0.6 $M_\odot$ and we can see that the observed period can easily be interpreted as the orbital one. To explain $\dot{P}$ let us note that the gravitational radiation leads to a loss of orbital angular momentum which in turn causes an increase of the mass transfer and an increase of the orbital period. This effect was first applied to explain some

of the dwarf novae properties[6,8]. The orbital angular momentum J and its change $\dot{J}$ due to the gravitational radiation are given by[9]

$$J = M_d M_{bh}\left(\frac{GR_{12}}{M}\right)^{1/2}, \qquad \frac{\dot{J}}{J} = -\frac{32G^3}{5c^5R_{12}^4} MM_dM_{bh} \tag{5}$$

Combining equations (1)-(5) we obtain the equation for M_d and its derivative $\dot{M}_d$, expressed in solar units ($m = M/M_\odot$):

$$\frac{\dot{m}_d}{m_d} = -1.3\times10^{-10}\, m_d^{11/3} m^{2/3} \frac{\left(1-\frac{m_d}{m}\right)^2}{1-\frac{5}{3}\frac{m_d}{m}} \tag{6}$$

The solution of equation (6) when $m_d \ll m$, together with equations (4) and (1), lead to the relations:

$$m_d = 0.6(1+6.3\times10^{-6}\, m^{2/3} t_d)^{-3/11} \tag{7}$$

$$\dot{M}_d = -4\times10^{-4}\, m^{2/3}(1+6.3\times10^{-6}\, m^{2/3} t_d)^{-14/11} M_\odot\ \mathrm{yr}^{-1} \tag{8}$$

$$P = 60(1+6.3\times10^{-6}\, m^{2/3} t_d)^{3/11}\ \mathrm{s} \tag{9}$$

$$R_{12} = 4\times10^9(1+6.3\times10^{-6}\, m^{2/3} t_d)^{2/11}\ \mathrm{cm} \tag{10}$$

where t_d is the time in days with $t_d = 0$ at the moment when $P = 1$ min. The curve $P(t_d)$ given by equation (9) approximately fits the observational points for $m = 5$ (see Fig. 1). The deviations of these points from a straight line may be due to the observational errors or to some phenomena, connected, for example, with the angular momentum exchange between the orbital and intrinsic rotation of the companions. The mass $M_{bh} = 4.4\ M_\odot$ is greater than the usually assumed value for the maximum mass of a neutron star of $2M_\odot$. The absence of radio emission and the very faint X-ray source also implies the absence of a neutron star in this system.

It has been suggested[10] that the evolutionary path leading to the formation of a binary system consisting of a degenerate dwarf and a relativistic star (a black hole or a neutron star) may start with a close pair of main-sequence stars of mass $\sim 11\ M_\odot$.

If the initial mass of the white dwarf in Geminga was $1\ M_\odot$, then the filling of the Roche lobe and the onset of the mass transfer and appearance of the γ-ray source happened ~ 130 yr ago, when the parameters of the system were: $P_{min} \approx 36$ s, $R_{12,min} \approx 3.6\times10^9$ cm. So, Geminga may be a very young γ-ray source. Before the Roche lobe filling phase (for $t \leq 0$) the system had been in a very quiet state for a long time. Gravitational radiation was decreasing the orbital period and the separation, according to equation (5) but with constants M_d and M_{bh}:

$$R_{12} = R_{12,min}\left(1-\frac{256G^3}{5c^5R_{12,min}^4} MM_dM_{bh}t\right)^{1/4}$$
$$= 3.6\times10^9(1-3\times10^{-11}\, mm_dm_{bh}t)^{1/4}\ \mathrm{cm} \tag{11}$$
$$P = P_{min}\left(\frac{R_{12}}{R_{12,min}}\right)^{3/2}$$
$$= 36(1-3\times10^{-11}\, mm_dm_{bh}t)^{3/8}\ \mathrm{s},\ t \leq 0$$

If the formation of the binary system had happened $<10^{17}$ s ago, initially it had parameters:

$$R_{12,0} \leq 1.5\times10^{11}\,(mm_dm_{bh})^{1/4}\ \mathrm{cm}$$
$$P_0 \leq 2.7\,(mm_dm_{bh})^{3/8}\ \mathrm{h} \tag{12}$$

In the future, mass transfer in Geminga will proceed up to the moment when a planet of non-ideal matter is formed and the mass transfer will stop. It follows from equation (7) that the transfer stage will proceed for at least a Hubble time $\sim 3\times10^{17}$ s, after which the period will be $P \approx 2.2$ h, $R_{12} \approx 10^{11}$ cm and $M_d \approx 4.5\times10^{-3}\ M_\odot$.

The present mass transfer rate, $\dot{M} \approx 10^{-3}\ M_\odot\ \mathrm{yr}^{-1}$, is very high. However, if Geminga is at a distance of about 100 pc (ref. 5) then its luminosity $L_\gamma \approx L_\odot$ can be explained by a much smaller accretion rate, $\sim 10^{-9}$-$10^{-11}\ M_\odot\ \mathrm{yr}^{-1}$, suggesting either a low efficiency of accretion or a non-stationary accumulation of matter in the accretion disk. Both these cases have been recently treated by authors (see refs 11, 12 and those cited in ref. 13) who considered geometrically thick, low-viscosity, laminar accretion flows onto black holes ('thick accretion disks').

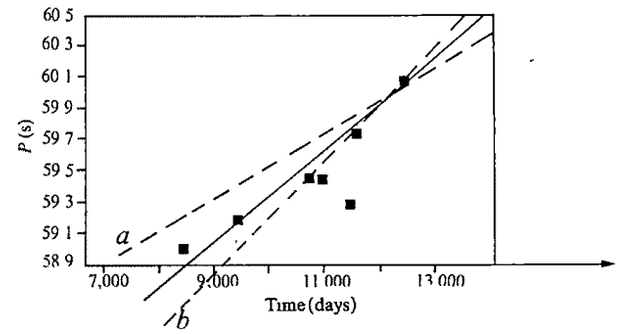

Fig. 1 The dependence of the period (in s) on time (in days). ■, Observational data[19]. The lines are calculated from equation (9). Solid line corresponds to $m = 5$, the dashed line a to $m = 3$, and the dashed line b to $m = 7$. All three lines meet at the point $P = 60$ s, $t = 12{,}120$ days.

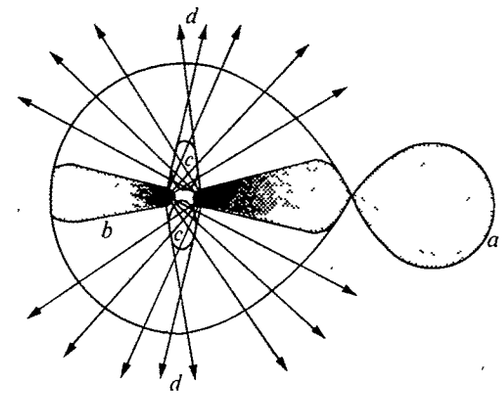

Fig. 2 The model of Geminga *a*, White dwarf filling its Roche lobe; *b*, accretion disk around black hole; *c*, regions of formation of the γ-ray emission due to collisions of relativistic particles; *d*, the beam of relativistic particles.

If the magnetic field is frozen into the matter of the disk, then the induced electric field accelerates the charged particles up to relativistic energies in the funnel of the thick disk which forms along the rotation axis[13]. The interaction of the relativistic particles may lead to the formation of π^0 mesons with the subsequent decay to γ-quanta. The qualitative picture of the model of Geminga is presented in Fig. 2. As in the Crab and Vela[14] the energy losses in the form of relativistic particles may be 100–1,000 times greater than L_γ. The rotation of the thick disk must be nearly uniform so that the magnetic field will not be strongly amplified and the quasi-stationary state of the disk may be preserved for a long time.

If the X-ray flux is formed by the interaction of the relativistic flow with the surface of the dwarf and the disk, then only a small part of the energy flux reaches these surfaces. Due to the reflection effect, we may expect optical variations with the same period $P \approx 1$ min and periodical Doppler shifts of the spectral lines from the dwarf with the amplitude $\approx 4{,}200 \sin i$ km s^{-1}, where i is the unknown angle between the normal to the orbital plane and the line-of-sight. The optical observations may serve as a decisive test for the validity of this model.

The development of turbulence in the accretion disk may lead to a strong X-ray emission $L_X \approx L_{edd} \approx 5\times10^{38}$ erg s^{-1}, but the duration and the frequency of such bursts are impossible to predict within the present model.

If the other unidentified point-like γ-ray sources[15] are of the same origin as Geminga, then we may expect similar L_γ/L_X and L_X/L_{opt} ratios and a periodic modulation of the γ-ray flux with $1\ \mathrm{min} \leq P \leq 3$ h.

The main energy losses by Geminga in this model are due to gravitational radiation. Using the standard quadrupole formula[9] and equation (10) we may write for the gravitational wave luminosity L_G:

$$L_G = \frac{32}{5}\frac{G^4}{c^5}\frac{M_d^2 M_{bh}^2 M}{R_{12}^5} \approx 6\times10^{39}(1+1.8\times10^{-5}\,t_d)^{-10/11}\,\mathrm{erg\,s^{-1}} \quad (13)$$

At a distance of 100 pc, this corresponds to a value of the flux on the Earth of

$$F_G = 5\times10^{-3}\,\mathrm{erg\,cm^{-2}\,s^{-1}} \quad (14)$$

This flux is about seven orders of magnitude greater than the flux from any other known binary system[16].

In the case of supernovae explosions, a high deviation from spherical symmetry and high infall velocities must be assumed to allow a detectable amount of gravitational radiation. There are doubts[17,18] over whether such high values are consistent with real supernovae events. On the other hand, our model of Geminga employs simple arguments and realistic parameters for the binary system. Thus the search for gravitational radiation (at $\nu \sim 1/30$ Hz) from Geminga would probably not be less reasonable than the search for the pulses of gravitational radiation from supernova explosions.

I thank G. F. Bignami for attracting my attention to Geminga, and V. I. Slysh and V. B. Braginskii for helpful discussions.

General relativistic effects on the pulse profile of fast pulsars

B. Datta & R. C. Kapoor

Indian Institute of Astrophysics, Bangalore 560034, India

The recent discovery of millisecond pulsars[1,2] has led to several theories about the structure[3–8] and radiation characteristics[9–11] of rapidly rotating neutron stars. The rapid rotation rate implies that such pulsars will be compact[5] (implying large space-time curvature) and that surface emission characteristics will differ significantly from the non-rotational (Schwarzchild) case[11]. We report here the implications of large space-time curvature and large rotation (specifically, the dragging of inertial frames introduced by rotation) on the trajectories of photons, and hence, on the pulse profile of fast pulsars. Space-time curvature leads to substantial amounts of divergence in the pulse width and reduction in the pulse intensity whereas rotation produces a tilt of the pulse cone from its original direction of emission, and deforms the cone, introducing an asymmetry in the (flattened) pulse profile leading to a time delay in the arrival of photons emitted within the pulse cone. We find that the effect of curvature dominates over that of rotation, suggesting a larger brightness temperature than inferred observationally for all pulsars whatever the rotation rate (unless the pulsar is of very low mass).

The full rotational analogue to the Schwarzchild space-time, namely the Kerr metric, does not have a corresponding appropriate interior solution amenable to a straightforward theoretical treatment. However, a rotationally-perturbed interior spherical metric of the following form[12,13] is adequate (signature +−−−)

$$ds^2 = g_{\alpha\beta}\,dx^\alpha\,dx^\beta = e^{2\nu}\,dt^2 - e^{2\psi}(d\phi - \omega\,dt)^2 - e^{2\mu}\,d\theta^2 - e^{2\lambda}\,dr^2 \quad (1)$$

where ω is the angular velocity of the cumulative dragging of inertial frames and ν, ψ, μ, λ depend on the structure of the rotating neutron star. This metric is valid for strong gravitational fields and for a uniform rotation rate that has as its upper bound the critical speed for centrifugal breakup. Neutron star models which rotate at the secular instability limit (assuming the star to be homogeneous) and which are relevant to fast pulsars, are within this bound[6].

Rotating neutron-star structure parameters using the metric (1) (see refs 5, 6) can be used in an external metric (which match at the surface) for calculating the photon trajectories. Space-time curvature will bend a photon trajectory, and rotation will drag it away from its original direction towards the direction of rotation. The net angle of deflection in the trajectory will be given by

$$-\phi_0(\delta) = \int_{r_e}^{D} \frac{d\phi/d\Gamma}{dr/d\Gamma}\,dr \quad (2)$$

where Γ is an affine parameter and r_e and D are respectively the radial locations of the emission and reception of the photon. The deflection angle is a function of δ, the azimuthal angle at which the photon is emitted with respect to the radius vector of the source through the origin of coordinates as seen in the local rest frame of the star ($\delta = 0$ corresponds to a radially outgoing photon and $\delta = 3\pi/2$ to a tangentially-forward photon). We have neglected the polar bending ($d\theta/d\Gamma = 0$) which will be small because we use a perturbed spherical geometry. Therefore, the polar angle of emission, θ_s, made by the line-of-sight through the centre of the star with respect to the rotation axis can be taken to be identical to the angle of inclination seen by a distant observer.

The lagrangian for the metric (1) is

$$L = \tfrac{1}{2}\{e^{2\nu}\dot{t}^2 - e^{2\lambda}\dot{r}^2 - e^{2\mu}\dot{\theta}^2 - e^{2\psi}(\dot{\phi} - \omega\dot{t})^2\} \quad (3)$$

where the overdot indicates derivative with respect to Γ. The equations of motion corresponding to equation (3) provide $\dot{\phi}$ and $\dot{t}$ whereas $\dot{r}$ is obtained from the null condition. Evaluated thus, equation (2) becomes

$$-\phi_0(\delta) = \int_{r_e}^{D} f(r, q_e)\,dr \quad (4)$$

$$f(r, q_e) = \frac{\omega(1+\omega q_e) - q_e\,e^{2\nu-2\psi}}{e^{\nu-\lambda}\{(1+\omega q_e)^2 - q_e^2\,e^{2\nu-2\psi}\}^{1/2}} \quad (5)$$

Here q_e is the impact parameter of the photon at the emission location, and has the form[11]

$$q_e = \left.\frac{e^{\psi-\nu}(v_s + \sin\delta)}{1 + e^{\psi-\nu}(\omega v_s + \Omega\sin\delta)}\right|_{r=r_e} \quad (6)$$

where Ω is the angular velocity of the star as seen by a distant observer and

$$v_s = e^{\psi-\nu}(\Omega - \omega) \quad (7)$$

Because of bending (see Fig. 1), the space-time curvature will cause a divergence in the pulse width. As a measure of this

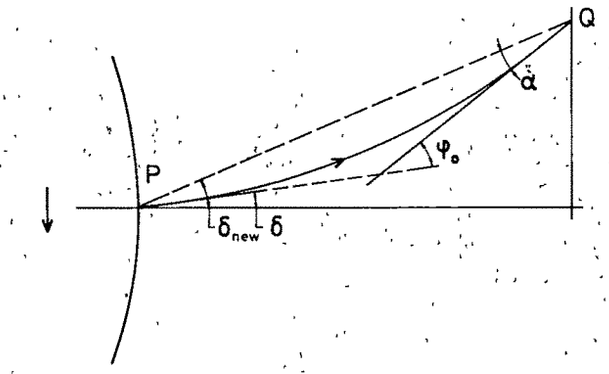

Fig. 1 Schematic illustration of the trajectory of photon starting from P at (or near) the pulsar surface in terms of the azimuthal angle of emission (δ) and bending ($\phi_0 \equiv \delta_{new} - \delta$). For an observer at infinity (denoted by Q), the angle $\alpha \to 0$. The arrow implies the direction of rotation of the neutron star.

divergence effect, we introduce a parameter Δ defined as

$$\Delta = (\mathrm{d}\delta_{new}/\mathrm{d}\delta)_{r=r_e} = (1 + \mathrm{d}\phi_0/\mathrm{d}\delta)_{r=r_e} \quad (8)$$

where

$$\delta_{new} = \delta + \phi_0(\delta) \quad (9)$$

As a consequence of rotation, the impact parameter is asymmetric in $\pm\delta$ and

$$\Delta(\delta, r) \neq \Delta(-\delta, r)$$

implying an asymmetry in the pulse profile (assuming the initial profile to be symmetric). This is unlike the Schwarzchild case, where although the space-time curvature will produce a pulse divergence effect of similar extent, there will be symmetry in $\pm\delta$.

The pulse divergence described above will imply a reduction in the pulse intensity, which can be understood in terms of conservation of energy flux. We denote the intensity deamplification factor by ε:

$$\varepsilon = \frac{I(\delta_{new})}{I(\delta)} = \frac{1}{\Delta}\frac{\sin\delta}{\sin\delta_{new}} \quad (10)$$

The factor ε must be corrected for redshift effects as follows, using Liouville's theorem[14]. If I_ν is the observed specific intensity and I_{ν_0} the emitted (monochromatic) specific intensity (at a given δ), then

$$I_\nu = I_{\nu_0}(\nu/\nu_0)^3 = I_{\nu_0}(1+z)^{-3} \quad (11)$$

where $(1+z)$ is the redshift factor[11]:

$$1 + z = \frac{1 + \Omega q_e}{e^\nu (1 - v_s^2)^{1/2}} \quad (12)$$

The redshift correction to the intensity through a factor $\{1 + z(\delta = 0)\}^{-3}$ is inherent to the pulse. Apart from this, the intensity will become enhanced for forward emitted photons ($\delta < 0$) and reduced for backward emitted photons ($\delta > 0$). We define a net intensity deamplification factor ε' that corrects ε for Doppler boosting (for $\delta < 0$) and dimunition (for $\delta > 0$) as

$$\varepsilon' = \varepsilon\left\{\frac{1 + z(0)}{1 + z(\delta)}\right\}^3 \quad (13)$$

in accordance with Liouville's theorem.

To illustrate the effects of space-time curvature and rotation on the pulse profile, we consider PSR1937+214, assuming its mass to be $1.4\,M_\odot$ ($M_\odot$ = solar mass). For this pulsar, $\Omega = 4.0334 \times 10^3$ rad s^{-1}; the relevant structure parameters for the

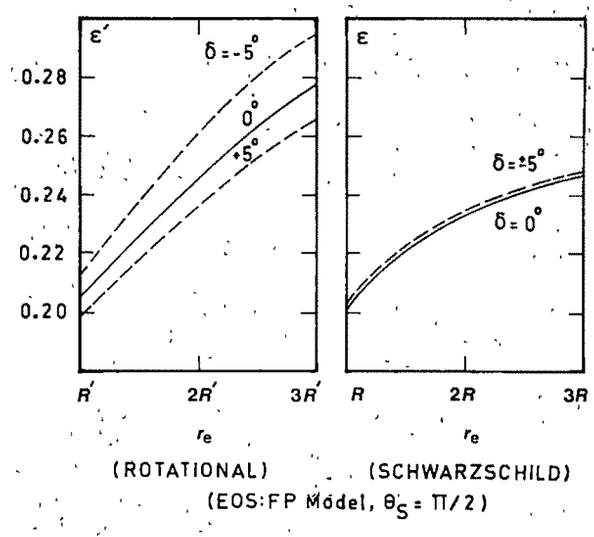

Fig. 2 Net deamplification factor (ε') versus φ radial emission location (r_e). EOS: FP model, $\theta_s = \pi/2$.

calculation have been taken from our earlier work[5,6] (corresponding to the Friedman–Pandharipande equation of state of neutron-star matter). As this pulsar is close to the point of secular rotational instability[5,6] the results will refer to maximal effects of rotation.

There is no general consensus on the mechanism of pulse emission. Here, we have selected one of the more popular models[15], namely, that in which the emission (at a particular frequency) emanates from a point near the surface of the pulsar in the form of a narrow cone (of angle $\leq 10°$) which rotates with the pulsar, sweeping the pattern past the observer. For the purposes of calculation, we take the initial pulse to be a gaussian curve with $-5° \leq \delta \leq +5°$.

The results of our calculations for the rotational (for $\theta_s = 0.3\pi$, 0.5π) and Schwarzchild ($\theta_s = 0.5\pi$ here) cases are summarized in Tables 1 and 2. The initial pulse becomes wider by a factor ~ 2. There is an asymmetry in the pulse profile brought about by rotation which manifests itself in the pulse cone getting compressed for backward emission and stretched for forward emission. This asymmetry, characterized by $|\Delta(+\delta) - \Delta(-\delta)|$, is

proportional to δ. This is also evident in ε'. Figure 2 illustrates (for $\delta = 0°, \pm 5°$) the variation $\varepsilon'(r_e)$, r_e being taken in units of $R'(R)$ which is the radius of the rotating (non-rotating) neutron star.

One interesting result of our calculations is the 'sweeping' of the entire pulse cone in the direction of rotation of the pulsar, thus imparting a tilt to the cone. The tilt can be understood in terms of the net bending of the radially outward $\delta = 0$ photon, whose values for various θ_s and r_e are given in Table 2.

In Schwarzchild space-time, photons emitted at $\pm\delta$ would have the same time of flight to the distant observer. But with the neutron star rotating rapidly, this symmetry will not be maintained. The backward emitted photons would have larger time of flight than the forward emitted photons. The difference in the arrival times of $\pm\delta$ photons, which we call time delay, can be evaluated from the equations of motion of photons in the external space-time and their redshifts. These values are listed in Table 2. If the time delay between photons with maximum δ and minimum δ equals the pulse duration, the complete pulse will be detected by the observer. If, however, this time delay exceeds the pulse duration, then, photons with δ larger than a critical δ will miss the detector. As a result, the pulse will have a gradual buildup but a steeper falloff. This will be a contributory factor to the asymmetry in the final pulse profile (apart from the effects resulting from inertial frame drag and interstellar/planetary scintillation, if any), and, in principle, will constrain the duty cycle of the pulsar.

The effects of curvature and rotation on the pulse profile presented here are purely general relativistic effects, and will be additional to any (frequency dependent) effect on the propagation of electromagnetic waves through anisotropic/inhomogeneous magnetized plasma. Observationally, most pulsars show narrow profiles. Our calculations, therefore, can be taken to imply that at the emission location, the pulse starts out in the shape of a narrow spike. As the brightness temperature of the source is directly proportional to the intensity of radiation, the important conclusion that follows is that the brightness temperatures of pulsars in general (since the curvature effects are dominant over the rotational effects) are larger by an order of magnitude (in the emitter's frame of reference) than are presently presumed.

We thank Professors J. V. Narlikar, Ch. V. Sastry, V. Radhakrishnan and our colleagues at the Raman Research Institute, for helpful discussions. B.D. acknowledges the Indian National Science Academy for the award of Biren Roy Trust Fellowship.

Possible precipitation of ice at low latitudes of Mars during periods of high obliquity

Bruce M. Jakosky

Laboratory for Atmospheric and Space Physics, University of Colorado, Boulder, Colorado 80309, USA

Michael H. Carr

US Geological Survey, Menlo Park, California 94025, USA

Most of the old cratered highlands of Mars are dissected by branching river valleys that appear to have been cut by running water[1,2] yet liquid water is unstable everywhere on the martian surface. In the equatorial region, where most of the valleys are observed, even ice is unstable[3,4]. It has been suggested, therefore, that Mars had an early denser atmosphere with sufficient greenhouse warming to allow the existence of liquid water[5]. Here, we suggest instead that during periods of very high obliquities, ice could accumulate at low latitudes as a result of sustained sublimation of ice from the poles and transport of the water vapour equatorwards. At low latitudes, the water vapour would saturate the atmosphere and condense onto the surface where it would accumulate until lower obliquities prevailed. The mechanism is efficient only at the very high obliquities that occurred before formation of Tharsis very early in the planet's history, but limited equatorial ice accumulation could also have occurred at the highest obliquities during the rest of the planet's history. Partial melting of the ice could have provided runoff to form the channels or replenish the groundwater system.

That some mechanism must exist for replenishment of the equatorial inventory of water has been suspected on several grounds: (1) if the valleys formed in a manner analogous to terrestrial river valleys, by slow erosion of running water, then the volumes of water that would have flowed through them would have been so large that some recycling of water is implied; (2) although groundwater seepage has probably had a major role in formation of the valleys[6], several morphological characteristics suggest that precipitation was also involved, so that transfer of water from the atmosphere to the surface occurred[2]; (3) the unique characteristics of several martian landforms, particularly those formed by impact, have been attributed (although not uniquely) to the presence of ground ice in regions where it is unstable.

We have calculated the potential loss of water from the poles on the assumption that sublimation of the seasonal CO_2 cap during summer exposes a residual water-ice cap, as is currently the case for the North Pole[7,8] and may occasionally be the case for the South Pole[9]. The procedure followed here is similar to that used by Toon *et al.*[10]. Temperatures at the surface and down to depths of 7 m are calculated for ±85° lat. taking into account incident solar radiation, long-wave emission from the surface and atmosphere, conduction into the ground, sublimation and condensation of carbon dioxide and evaporation of water. Atmospheric pressures greater than the present value may occur at high obliquities as a result of desorption of CO_2 from the high-latitude regolith[11]. We assumed that the pressure was 40 mbar at 45° obliquity, 25 mbar at 35° obliquity and 10 mbar at the current 25° obliquity[12]. The main difference between our model and that of Toon *et al.* is that we included growth and decay of the CO_2 cap as an integral part of our model rather than assuming that the CO_2 cap disappeared at a specific time. Our results are conservative in that they give estimates of the

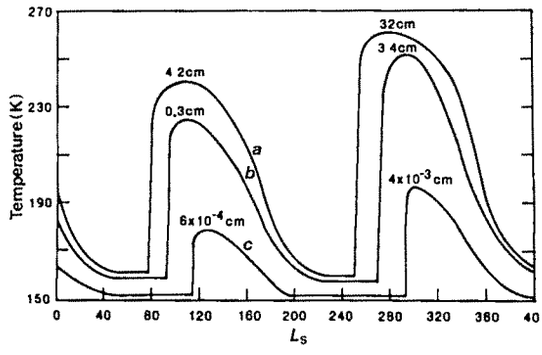

Fig. 1 Seasonal polar cap temperatures calculated for obliquities of 45° (*a*), 35° (*b*) and 25° (*c*). The adjacent numbers refer to the thickness of ice sublimed from the cap (in cm) during the entire summer. For clarity, only temperatures for the warmer pole are shown at each season. Calculations assume the maximum obliquity (0.14) and have periapsis at southern solstice, and thus yield the maximum differences between the two poles; other choices would yield temperatures intermediate between these extremes.

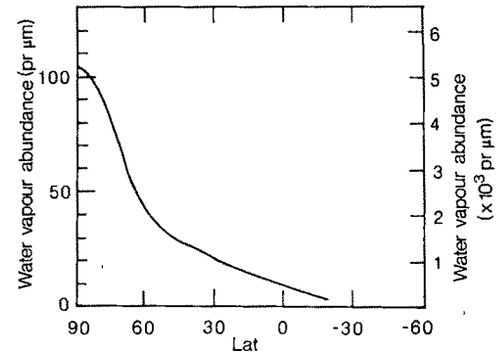

Fig. 2 Latitudinal distribution of water vapour at mid-summer in the north as observed from the Viking space craft (left-hand ordinate) The right-hand ordinate is appropriate for high values for the obliquity, when $\geq 5 \times 10^3$ pr μm water may be present over the cap

amount of water sublimed from the summer cap that are up to a factor of 10 lower than the estimates of Toon *et al.*[10].

Typical results are shown in Fig. 1 for the three values of the obliquity. Although the results are sensitive to factors such as the albedo of CO_2 and water frost, the wind speed and the assumed thermal conductivity, the results, in general, demonstrate that at 45° obliquity a few centimetres to a few tens of centimetres will be evaporated from the poles during each summer. At an obliquity of 35° a few tenths of a centimetre to a few centimetres will be lost, while in present conditions only 10^{-2}–10^{-4} cm are lost.

The results shown in Fig. 1 were calculated assuming sublimation of water into a dry atmosphere. The actual amount of water sublimed and its eventual fate will depend on the rate of atmospheric transport away from the pole. Figure 2 shows the mid-northern-summer latitudinal distribution of water vapour during 1976. Polar abundances of about 100 precipitable (pr) μm were observed, consistent with an almost saturated atmosphere[8,13]. Non-polar atomospheric water indicates transport of water away from the pole and/or exchange of water between the regolith and atmosphere[14,15], although transport from the poles ultimately dominates the process[15]. For equatorial and mid-latitude mixing timescales indicated by dynamic models[16,17], an amount of the order of 5×10^{14} g H_2O can be transported southwards each year, equivalent to removing $\sim 4 \times 10^{-2}$ g cm^{-2} from the cap[15,18]. Given the uncertainties in the models, this value is consistent with the estimated amounts of water that can be sublimed.

At high obliquity, a similar atmospheric circulation pattern should exist, with the exceptions of a poleward shift in the Hadley cell to the subsolar point, and more vigorous cross-equatorial transport (ref. 19 and R. M. Haberle, personal communication). Therefore, if we assume a similar mid-summer distribution of water with latitude due to transport from the polar region, we can use Fig. 2 to show the latitudinal variation at midsummer, reading now from the right-hand scale The estimate of 5×10^3 pr μm over the pole is conservative, based on saturation of the atmosphere over the pole at temperatures that are relatively low for 45° obliquity but higher than that of the present summer cap. By scaling the amount transported to the total abundance, the amount of water transported away from the cap is equivalent to removal of ~ 2 g cm^{-2} from the pole, again consistent with the amounts estimated to have sublimed. From the right-hand scale of Fig. 2, there can be >1,000 pr μm of atmospheric water at mid- and low latitudes. For less conservative assumptions, the amount of water ice sublimed can be as great as 20 cm and the water content of the atmosphere at the equator can be as high as 10,000 pr μm.

At the equator a dust-free atmosphere is capable of holding only as much as 100–200 pr μm of water vapour without saturating[20,21] Thus, the excess above this value will condense and form clouds. Persistent dust storms are, however, likely at high obliquities[5]. The presence of dust causes atmospheric temperatures to rise. As a result, the atmosphere could hold 5,000–10,000 pr μm during the day without saturating, and up to 300 pr μm at night[21]. Thus, even during dust storms water would condense out at night if abundances were higher than ~300 pr μm. If the dust acts as condensation nuclei for the water, then the dust and ice will be removed rapidly to the surface, possibly within several days. Two uncertainties are the effect of the ice clouds on the holding capacity of the atmosphere and the effect of surface ice. Temperatures that occur in the presence of clouds are not well determined; low-altitude clouds will cool the surface dramatically[22,23] while high-altitude clouds could increase surface temperatures[10]. The presence of high-albedo ice on the surface would significantly lower surface and atmospheric temperatures, thereby providing a positive feedback and enhancing the tendency for atmospheric water to condense.

If as much as 20 cm of ice are removed in 1 yr from the summer cap and deposited uniformly between ±45° latitude, the resulting ice thickness is 0.4 cm. It is uncertain, however, where the ice is deposited. The atmospheric circulation pattern and the relative timescales for condensation and settling will determine whether the ice is deposited near the edge of the summer or winter cap or more uniformly over the globe. During the following winter, the non-polar water vapour abundance at saturation will not change significantly, while the winter polar cap will have essentially no water vapour above it. The latitudinal gradient of water during winter is thus towards the pole, but is a factor of 5–50 smaller in magnitude than during summer, so that the rate of transport of water from low latitudes to the winter pole is probably low. Also, at the time when water is seeking to move back to the winter pole, additional water is being supplied from the other summer pole, further inhibiting evaporation. Ice will thus tend to accumulate in non-polar regions

The thickness of ice that could accumulate at low latitudes and the fraction of the obliquity cycle during which it would be stable depends on the amount of ice available at the poles and the range of the obliquity variations. Before the formation of Tharsis the mean obliquity was as high as 35° and the peak value as high as 45° (ref. 24). During the highest obliquities of this epoch, 2 km of ice could be removed from the poles in $<10^4$ yr to form ice deposits tens of metres thick in the non-polar latitudes, if that much polar ice is available. Ice may have returned to the poles only at minimum obliquities. During most of Mars' history, however, obliquities ranged from 15 to 35° (refs 24, 25). Net accumulation of ice in non-polar areas is then likely only at peaks in the obliquity cycle, and removal of as much as 2 km of ice from the poles is unlikely. The polar layered deposits could, however, be extensively reworked, as is suggested by the scarcity of superimposed impact craters[5,10].

Meltwater from the ice deposits may have contributed to the erosion of the branched valley networks. For melting temperatures to be reached at the surface by greenhouse warming, atmospheric pressures near 1 bar are required[26]. However, melting of snow or ice does not necessarily require surface temperatures to be above melting. The low thermal conductivity of snow and its partial transparency to sunlight can result in subsurface melting when surface temperatures are well below freezing[27]. Thus, melting can occur in substantially thinner atmospheres than are required by the atmospheric greenhouse effect alone. Another appealing reason to invoke a mechanism that requires high obliquities to explain the valley networks is that most of the networks formed very early in Mars' history[2,28]. At that time, the Tharsis bulge may not have reached its present size. As Tharsis grew, the maximum obliquities reached decreased, and as a result so did the efficacy of the equatorward transfer of water. Young valley networks are, therefore, rare.

Onset of the south-west monsoon and sea-surface temperature anomalies in the Arabian Sea

R. Kershaw

Meteorological Office, Bracknell, Berkshire RG12 2SZ, UK

In 1979, the year of the Global Weather Experiment, the atmosphere and ocean of the monsoon region were particularly well observed. For this reason, the onset period of the monsoon, 11–19 June 1979, was selected for international comparison of numerical prediction models[1]. Previous studies[2–4] have demonstrated that successful predictions for this period are difficult to achieve. I report here two examples of numerical predictions that highlight the role of sea-surface temperatures, namely a control forecast using climatological sea-surface temperatures and an anomaly forecast using more realistic (and warmer) surface temperatures specified for the eastern Arabian Sea. It is shown that the use of the more accurate sea-surface temperatures enables a better prediction of the development of a monsoon depression to be obtained.

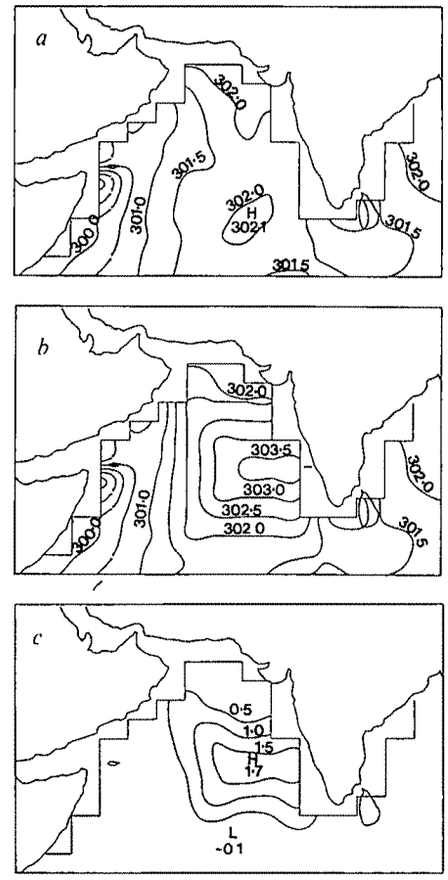

Fig. 1 *a*, Sea-surface temperature for control forecast; *b*, sea-surface temperature for anomaly forecast; *c*, sea-surface temperature anomaly (*b* − *a*). Contour interval, 0·5 K.

For these experiments, the 11-layer global atmospheric general circulation model[5,6] of the UK Meteorological Office was used with a horizontal resolution of 2° lat. and 3° long. The initial conditions for both forecasts were taken from the (level 3B) analysis for 12.00 GMT on 11 June 1979 made by the European Centre for Medium Range Weather Forecasts (ECMWF) using data which had been collected for the Global Weather Experiment. The sea-surface temperatures were fixed throughout the 8 days of each forecast. The values in Fig. 1*a* were derived from a climatological average for the decade 1951–60; those for the eastern Arabian Sea in Fig. 1*b* were based on an analysis by Seetaramayya and Master[7] for 8–15 June 1979. The difference chart (Fig. 1*c*) shows a maximum warm anomaly of 1.7 K in this region.

The onset of the monsoon is characterized by an increase in wind speeds at low levels over the Arabian Sea and the commencement of the rains along the west coast of India. Figure 2*a*, *b* illustrates the changes in the wind field at the 850-mbar pressure level during the onset period. On 11 June the south-westerly jet had a maximum speed of 14 m s^{-1} a few degrees to the east of the Somali peninsula, and the main branch of the monsoon flow was still to the south of India (Fig. 2*a*). During the next 8 days the jet strengthened and extended eastwards to the southern tip of India. A depression formed on the northern flank of the jet and moved first north then west, allowing the monsoon westerlies to advance northwards to cover much of the Indian peninsula and bring the rains to the west coast. By 19 June the maximum speed of the jet was 29 m s^{-1} and the cyclonic vortex of the depression was near the Arabian coast (Fig. 2*b*).

In the control forecast, the jet strengthened and extended eastwards more slowly than actually occurred, to give a maximum speed of only 24 m s^{-1} by 19 June (Fig. 2*c*). A weak vortex developed in the correct location, but the model failed to intensify it and kept it stationary. The anomaly run produced

a much better prediction of the intensification of the vortex and moved it northwestwards. By day 8, 19 June, the centre was at approximately the right latitude but ~5° too far east (Fig. 2*d*). The jet strengthened more than in the control integration, giving a maximum speed of 29 m s^{-1}.

The direct effect of increasing the sea temperatures is to increase the transfer of heat and moisture from the ocean into the atmosphere. Initially the increases are quite small, but after 8 days the differences between the anomaly and control runs (Fig. 3*a*, *b*) show maxima of 54 W m^{-2} for the sensible heat flux and 16 mm per day (460 W m^{-2}) for the rate of evaporation. The higher values in the anomaly forecast are consistent with

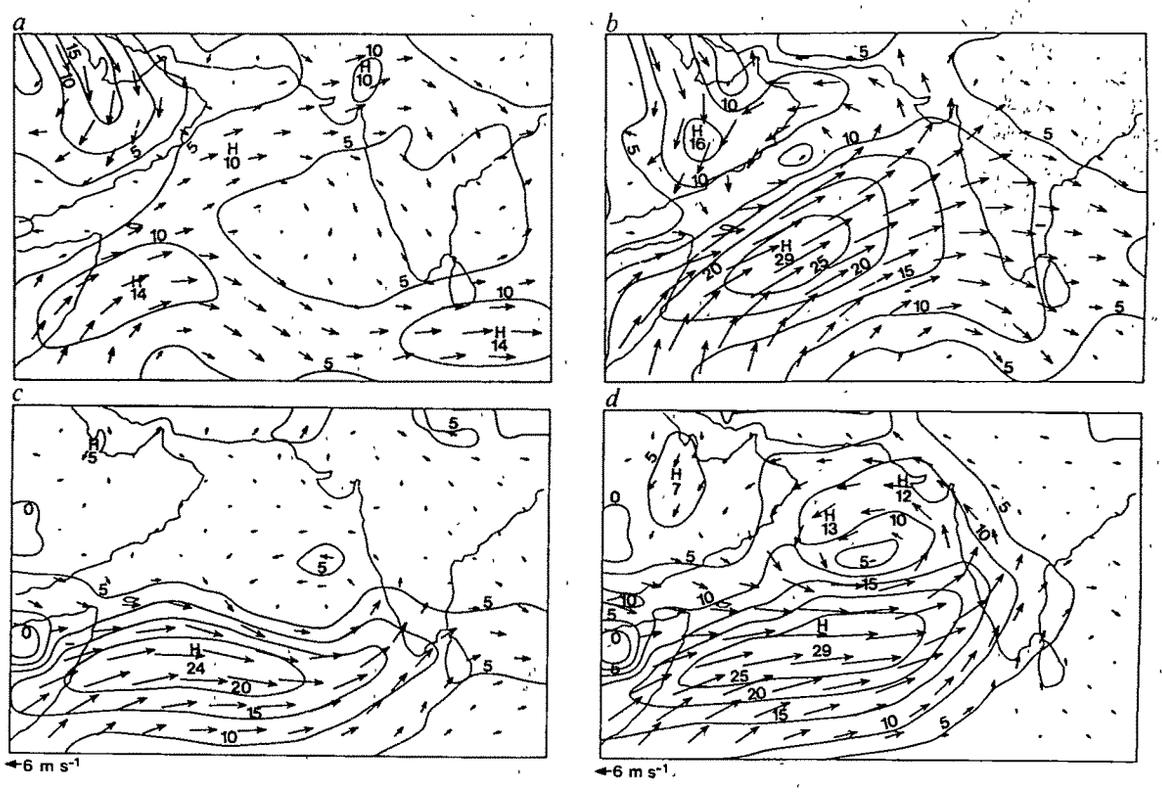

Fig. 2 Wind vectors and isotachs at 850-mbar pressure level (m s^{-1}). *a*, ECMWF analysis for 12.00 GMT 11 June 1979; *b*, ECMWF analysis for 12.00 GMT 19 June 1979; *c*, control forecast for 12.00 GMT 19 June 1979; *d*, anomaly forecast for 12.00 GMT 19 June 1979.

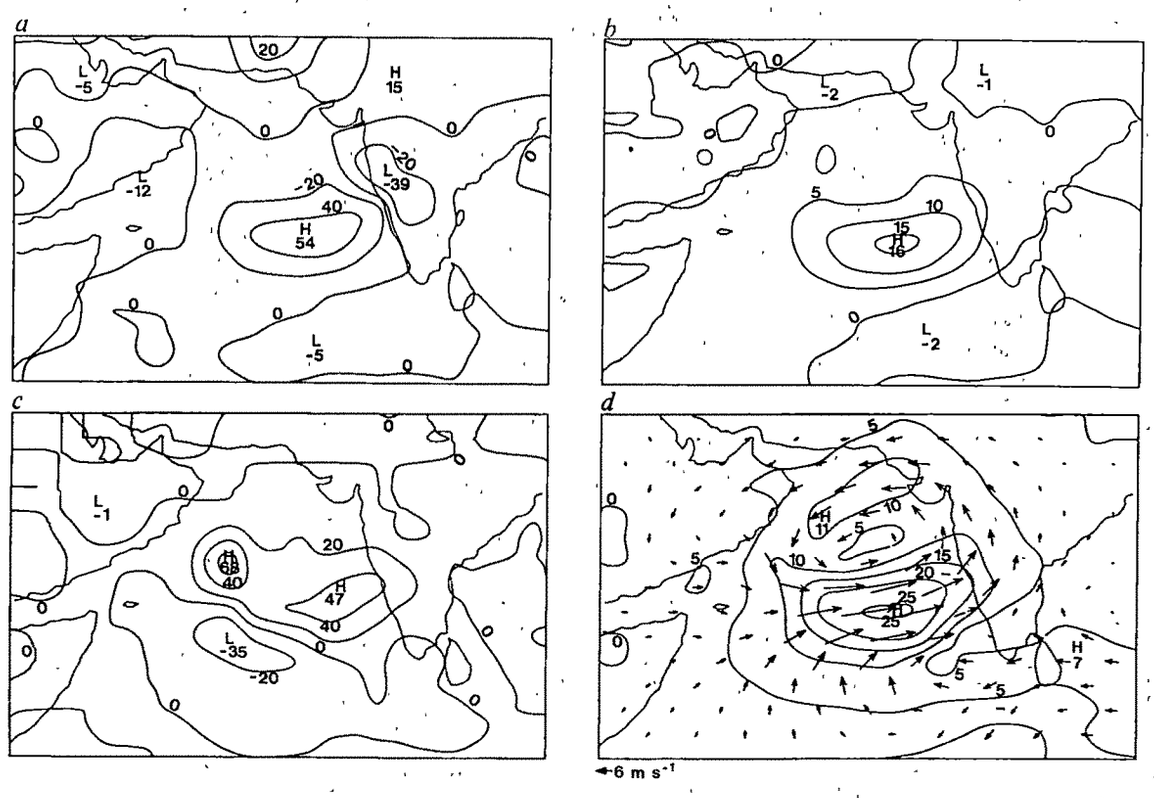

Fig. 3 Anomaly forecast minus control forecast for 12.00 GMT 19 June 1979. *a*, Upward sensible heat flux from surface (W m^{-2}); *b*, rate of evaporation from surface (mm per day); *c*, rate of precipitation (mm per day); *d*, vector wind at 850-mbar pressure level (m s^{-1}).

estimates of the fluxes for the onset period made from ship observations[8]. The changes in surface fluxes induce a substantial increase in precipitation. Figure 3*c* shows a maximum local increase of >65 mm per day after 8 days. This increase in precipitation is sustained partly by the increase in evaporation but mainly by increased moisture convergence. The additional latent heat released into the atmosphere is equivalent to a vertically averaged heating rate of around 16 K per day. This heating is compensated by adiabatic cooling associated with increased ascent. The response of the low-level wind field to these changes is shown in Fig. 3*d*. The main effect is confined to the Arabian Sea, with an asymmetrical cyclone centred to the north of the heating zone; the strongest flow is the westerly directly over this zone, and weak easterlies are induced to the south-east.

Figure 3*d* is qualitatively similar to Gill's[9,10] solutions for the response of a simple linear model to prescribed heating north of the Equator. The vertical structure of the response to the increased sea temperatures is also similar to that imposed in Gill's model. The vertical velocity shows a single peak in mid-troposphere and the flow in the upper troposphere is anticyclonic above the low-level cyclone This correspondence suggests that, in the general circulation model, the latent heat release is the critical factor in promoting the changes in the flow, although the mechanism is not simple. A positive feedback cycle is operating, whereby the increase in latent heat release leads to increased ascent and more moisture convergence at low levels. The ascent causes increased cyclonic flow at low levels, as in the simple model, and the stronger wind increase the surface fluxes of heat and moisture. These effects collectively lead to more precipitation, completing the cycle.

A much better prediction of the development of a monsoon depression over the Arabian Sea was obtained by specifying more accurate sea-surface temperatures in the region where the depression was formed. The strengthening of the low-level jet and the northward movement of the monsoon rains along the west coast of India were also greatly improved in the forecast with the warm anomaly. These features make this prediction the best yet achieved for the onset of the monsoon in 1979. The results have clearly indicated that correct sea-surface temperatures can be essential for accurate numerical weather prediction for the tropics.

I thank Dr R. A. Bromley for initiating this study and Mr P. V. Harker for help in running the computer programs.

1,200-Myr impact-melting age and trace-element chemical features of the Yamato-790964 chondrite

Noboru Nakamura*† & Osamu Okano†

Nada, Kobe 657, Japan

Age determinations of impact-produced materials in brecciated meteorites[1] are particulary important for understanding the evolutionary history of meteorites. The age characteristics of these meteorites have been examined mostly by the K–Ar method or, in a few cases[2], by the Rb–Sr method. However, age data are still rare and, except for a few cases[3], the large-ion lithophile (LIL) trace-element chemical features have not been studied in detail. In this respect, the Yamato-79 shocked meteorites are the best specimens for investigation. We report here results of Rb–Sr systematics and trace-element analyses for an almost wholly impact-melted LL-chondrite, Y-790964, one of the Yamato-79 unusual chondrites. The analyses yield an internal isochron age of 1,200±50 (2σ) Myr. The isotopic and trace-element data obtained represent the first clear evidence of the youngest impact-melting and LIL-element fractionations for a complete LL-chondrite, and suggest that the 1,200-Myr-age is a non-trivial marker in the evolution of meteorites.

The meteorite, originally weighing 3.3 kg, has a porous and microcrystalline texture with euhedral, chemically zoned pyroxene and olivine and minor relic chondrules[4,5], and has a similar major-element composition to that of normal LL-chondrites[6]. Two whole rocks from the different portions (A and B) and eight mineral separates from portion A of the meteorite were examined for Rb-Sr systematics, rare-earth elements (REE), Ba, Sr, Rb, K, Mg, Fe and Ca abundances (Tables 1-3). The trace and major elements were determined using the mass spectrometric isotope dilution method similar to that of Nakamura[7] or using an electron probe microanalyser. In additon, major-element compositions in the constituent minerals were analysed for a thin section of the bulk meteorite by an electron probe. Total blanks for all chemical processes were 0.02 ng for Rb and 0.08 ng for Sr, corresponding to <0.2% of the respective elements in most samples except for analyses of the 1 M HCl leached fraction F2-MS. The Rb-Sr data (Table 3), after corrections of the blank, are, in general, quite accurate. Details of our experimental procedures will be published elsewhere[8].

The results for the bulk samples show that abundances of major, minor and trace elements are almost within the range of those in normal LL-chondrites. However, note that two REE patterns, normalized to the average of six normal LL-chondrites, are similar, high and slightly upwardly convex with small negative Eu anomaly, and that abundances of Ba, Rb and K are

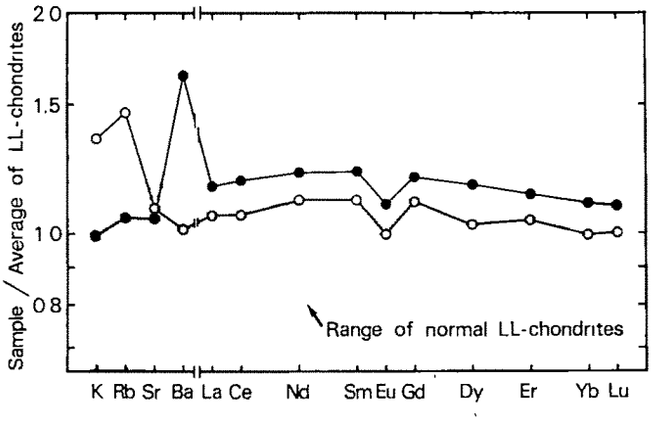

Fig. 1 Trace-element abundance pattern of the Yamato-790964 LL-chondrite. Abundances are normalized to the average of normal LL-chondrites Note that most of the elemental abundances in the meteorite are within the range of normal LL-chondrites but show systematic fractionations in REE, Rb and K from those of normal chondrites WR-A (○) and WR-B (●) are whole-rock samples from portions A and B, respectively.

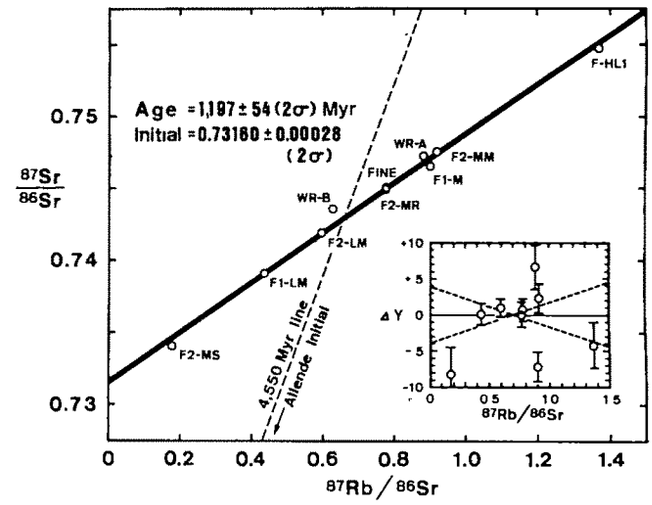

Fig. 2 ^{87}Rb–^{87}Sr evolution diagram of the Yamato-790964 LL-chondrite. Note that data points form roughly an array but show some deviations from the regression line, suggesting the Rb–Sr isotopic system of the meteorite was almost but not completely reset by the 1,200-Myr-melting event.

rather variable. A similar trace-element feature has been found for other Yamato-79 unusual meteorites[8] The variable distributions of alkali metals in LL-chondrites have also been reported for other non-Antarctic LL-chondrites[3,9,24].

A thin section of the meteorite reveals a heterogeneous distribution of numerous vesicles (covering ~20% in the total area) and brown glass or microcrystalline materials (~5% in the area) associated with vesicles. Euhedral, chemically zoned pyroxene ($En_{69}Fs_{24}Wo_7$ at the core, $En_{47}Fs_{15}Wo_{38}$ at the rim) and homogeneous olivine ($Fa_{29}Wo_{71}$) exist within the glass and/or microcrystalline matrix. The glasses show variable chemical compositions, ranging from 50 to 85% of normative Na-rich plagioclase (An30–An10); SiO_2 = 45–61, Al_2O_3 = 23–30, TiO_2 = 0.2–5, FeO = 0.6–6.5, MgO = 0.2–1.6, CaO = 2–7.6, Na_2O = 4–6.5, K_2O = 0.1–0.2%. We could not recognize any particular clast but noted minor relic (radial pyroxene or barred olivine) chondrules and rounded troilite-like opaque minerals in metal grains in some areas. The general petrological features suggest that the meteorite was once heated beyond the metling point of metal/troilite, reaching the melting points of silicate minerals (1,200–1,400 °C)[10] within a short time, and that melting and/or metamorphic recrystallization ensued for the whole stone, followed by rapid solidification.

These chemical and petrological features suggest that the observed variations in absolute abundances of REE, Ba, Rb and K in the bulk samples are due to heterogeneous distributions of glasses which may carry high and variable LIL trace elements. The value of ~10% for the negative Eu anomaly in both bulk samples suggests that the meterorite was related to plagioclase-controlled partial melting. For example, assuming 10–20% equilibrium partial melting of plagioclase+pyroxene (+olivine) in an LL-chondritic source, segregation of the melt from the source and addition (~10%) to a typical LL-chondrite, we would obtain 1.2–1.3 times LL-chondritic REE abundances with 10–15% negative Eu anomaly, which is similar to those of the bulk samples. Hence, the meteorite could represent an impact-produced partial melt that was removed from its point of origin and which assimilated unfractionated material before recrystallization.

In Table 3, except for the leached fraction, the olivine-rich fractions generally have larger $^{87}Rb/^{86}Sr$ ratios while the less olivine-rich and more pyroxene-rich fractions have the smaller $^{87}Rb/^{86}Sr$ ratios. However, the 1 M HCl-leached fraction (F2-MS) with highest normative olivine composition unexpectedly shows the lowest $^{87}Rb/^{86}Sr$ ratio, although the Rb and Sr concentrations are reasonable. There is no obvious explanation for this, but it is possible that low Rb/Sr component(s) were added to the fraction by dissolution (~18%) of the microcrystalline materials. Some minor irregularities of the Rb/Sr system are also noted among other mineral separates, indicating complex effects of Rb–Sr-rich components such as glass on the Rb–Sr systematics of the meteorite. Nevertheless, the relatively large spread of $^{87}Rb/^{86}Sr$ ratios obtained here, ranging from 0.18 to 1.4, is interesting.

In an ^{87}Rb–^{87}Sr evolution diagram (Fig. 2), all the data points obtained roughly show an array. However, the data point of whole rock B deviates markedly from the general trend. Excluding whole rock B, nine data points define a best-fit linear regression line, which yields an age of 1,197 ± 54 (2σ) Myr and an initial $^{87}Sr/^{86}Sr$ ratio of 0.73160 ± 0.00028 (2σ). Despite a large range of values of $^{87}Sr/^{86}Sr$ among the mineral separates, the errors in age and initial ratio obtained here are large. This is apparently caused by dispersion of some data points beyond analytical uncertainties, as shown in the inset to Fig. 2. Note that three samples (F2-MS, F2-MR and F-HL1) were treated with ≤1 M HCl and Clerici's solutions for mineral separation and washing. Although there are minor analytical problems with these samples a close examination of the analytical data suggests that a possible selective leaching of Rb to Sr is not too serious. Also we must consider the potential importance of a weathering effect on the trace-element behaviour in Antarctic samples[11] when evaluating such problems. However, since the specimens analysed in this work were sampled from the inner part of the meteorite and appeared quite fresh under the binocular microscope, the observed isotopic disturbances are considered to be real Specifically, deviations of data points of whole rock (WR) A, B and F1-M are the most significant.

Because the weighted mean ratios of $^{87}Rb/^{86}Sr$ and $^{87}Sr/^{86}Sr$ of mineral separates are similar to those of whole rock A, this rock may roughly represent portion A of the meterotie in terms of Rb–Sr systematics, but not necessarily the total meteorite. Note that the Rb/Sr data of whole rock A ($^{87}Rb/^{86}Sr$ = 0.881), as well as those of whole rock B ($^{87}Rb/^{86}Sr$ = 0.629), fall off significantly from the 4,500-Myr evolution line, suggesting that the meteorite was subjected to severe Rb/Sr fractionation at the time of the 1,200-Myr thermal event. Assuming a two-stage evolution, formation of the meteorite parent body with the same initial $^{87}Sr/^{86}Sr$ ratio as the Allende meteorite (bias-adjusted value = 0.69884)[12] at 4,500 Myr ago, and Rb/Sr fractionation at 1,200 Myr ago, the $^{87}Rb/^{86}Sr$ ratio of the meteroite at the time of formation is calculated to be 0.67. This value is 24% smaller than that of whole rock A but is similar to the $^{87}Rb/^{86}Sr$ ratio

Table 2 Major element and estimated mineral composition for specimens from the Yamato-790964 LL-chondrite

Sample		MgO (%)	FeO (%)	CaO (%)	Ol (%)	Opx (%)	Cpx (%)	Gls (%)	Other (%)
Whole rock

Major elements were determined by an electron probe microanalyser for 100–300 grains from the mineral separates except for samples of WR-A, WR-L, F2-MS and F-HL1, which were analysed by isotope dilution. Mineral compositions were estimated from the distribution of the major-element composition for each grain. Ol, Olivine; Opx, orthopyroxene; Cpx, clinopyroxene; Gls, glass; other, microcrystalline materials + metal + troilite.

* Soluble (F2-MS) and insoluble (F2-MR) fractions obtained by leaching F2-MB with 1M HCl for 80 h at room temperature.

† Separated by Clerici's solution ($3.37 < \text{density} < 3.45\ \text{g cm}^{-3}$) and washed with dilute HCl before analysis.

of most LL-chondrites[9,24]. Therefore, we suggest that the meteorite had a typical LL-chondritic Rb/Sr ratio between 4,500 and 1,200 Myr and that an enrichment of Rb relative to Sr occurred 1,200 Myr ago. Such a Rb/Sr fractionation is in accordance with the melting-assimilation model deduced from the REE data mentioned earlier, and is also consistent with the trace-element data for the associated meteorites[8]. However, the inconsistent behaviour of Rb/Sr with the REE which is observed for whole rock B, and the lack of complete isotopic equilibration of both whole rocks (A and B shift to the left of 1,200-Myr isochron) indicate that the effects of the 1,200-Myr thermal event on the Rb/Sr systematics of the meteorite were very complex. Considering such isotopic evidence, together with the REE, Ba and K data, we suggest that the chemical and petrological characteristics of the meteorite are best explained as the result of intense impact(s) which yielded partial melting and assimilation of the regolith on the LL-chondrite parent body ≤1,200 Myr ago.

It is interesting that the 1,200-Myr age obtained for the Yamato-790964 meteorite is the youngest so far reported for impact-produced lithic materials in brecciated meteorites. Most such meteorites show significantly older ages (>3,400 Myr)[12–14] with the exception of the H-clast in the St Mesmin LL-chondrite which shows a 1,400-Myr K–Ar age[15]. Moreover, except for SNC meteorites, the Yamato-790964 LL-chondrite would be the first complete stone to show the latest crystallization age.

Because no chemical and petrological similarities seem to exist between the LL-related chondritic material mentioned above and SNC meteorites, a possible genetic relation between the two may be ruled out. The 1,300-Myr age obtained for SNC meteorites[16–21] has been explained as a crystallization age which marks extensive volcanic activity on a well-differentiated planet such as Mars[20,21]. On the other hand, the 1,200–1,400 Myr age obtained for the Y-790964 and St Mesmin meteorites is interpreted as signifying a time of strong impact activity on the LL-chondrite parent body (asteroidal planet). How are these facts related? We are increasingly puzzled that all the major young perturbing events observed for meteorites have an age close to 1,200– ~ 1,400 Myr. As the number of results increases, one should examine whether this is a real effect of a major impact-related event on meteorite parent planets or a sampling bias. In the former case, like the 4,000-Myr lunar cataclysm, one should look for collision and storage processes lasting for billions of years.

In any case, in view of the large amount of the similar types of meteorite found in the Yamato Mountain area, Antarctica, we suggest that the 1,200-Myr age obtained here is a non-trivial marker in the evolution of meteorites.

We thank Professors T. Nagata and K. Yanai for providing the meteorite specimen and for the loan of the thin section, Dr H. Takeda for information on impact-melted meteorites, Professor H. Honma for use of the mass spectrometer and electron probe microanalyser, Professor H. Goto for cooperation, and Dr J. F. Minster for helpful suggestions. O.O. thanks Professor K. Ito for support and encouragmeent. Mrs H. Wada typed the manuscript. This research was supported, in part, by Grants in Aid for Scientific Research from the Ministry of Education, Science and Culture, Japan (59540367 to N.N. and 59390007 to K. Nakazawa).

Table 3 Results of Rb–Sr analyses for the whole rocks (WR) and mineral separates from the Yamato-790964 LL-chondrite

Samples	Weight (mg)	Rb (p.p.m.)	Sr (p.p.m.)	$^{87}Rb/^{86}Sr$	$^{87}Sr/^{86}Sr$
WR-A	52	3.669	12.09	0.881	0.747205 ± 128
WR-B	50	2.559	11.82	0.6285	0.743553 ± 53

NBS 987 standard (mean of 10 runs)					0.710212 ± 21†

Isotopic analyses were carried out at Okayama University using a mass spectrometer model MAT-261. Precisions for $^{87}Rb/^{86}Sr$ are estimated to be better than 0.8% except for the F2-MS. $^{87}Sr/^{86}Sr$ ratios are normalized to $^{86}Sr/^{88}Sr = 0.1194$. Errors correspond to last digits and are at the 95% confidence limit.

* Calculated weight which contains 10% uncertainty.

† Ratio is in agreement with our previous analysis[19].

Melting of peridotite to 14 GPa and the genesis of komatiite

Eiichi Takahashi & Christopher M. Scarfe*

Institute for Study of the Earth's Interior, Okayama University, Misasa, Tottori-ken 682-02, Japan

It is generally accepted that the Earth's upper mantle is made of peridotite[1,2]. In volatile-absent conditions, partial melting of mantle peridotite close to the solidus yields a variety of basaltic melts that are progressively more olivine-normative with increasing depth[3,4]. At 3–4 GPa (30–40 kbar), the highest pressures so far investigated, the melts are picritic with up to 20 wt% MgO (ref. 5). Basaltic magmas that are dominant on the Earth's surface today, therefore, are considered to have been generated at relatively shallow depths (< 100 km)[1–6]. Here we extend the pressure range of the melting experiments to 14 GPa and show that melts close to the peridotite solidus at 5–7 GPa are no longer basaltic but are komatiitic with >30 wt% MgO. Based on these results, we describe a model for the genesis of komatiite magmas by partial melting at depths of 150–200 km in the Archaean upper mantle.

The starting materials for the experiments were two lherzolites (Table 1). KLB-1 is a protogranular spinel lherzolite from Kilbourne Hole[7], New Mexico, and PHN1611 is a sheared garnet lherzolite from Thaba Putsoa[8], Lesotho. Both may represent undepleted mantle material and are close to pyrolite-III[9] in composition. Garnet lherzolite PHN1611 has been previously investigated at pressures ≤3.5 GPa (refs 10–13).

Crushed powders (<5 μm) were dried at 1,000 °C at the NNO (Ni–NiO) buffer. Wire loop experiments[14] were performed at 1 atm in a controlled CO_2–H_2 atmosphere close to the NNO buffer. Experiments at 1.5 and 3 GPa were carried out with a piston-cylinder apparatus[15] using a 0.5-inch talc–Pyrex assembly. Run conditions, methods and procedures are similar to those described in ref. 5.

At 5 GPa and above, a split-sphere apparatus[16] at Okayama University was used. Up to 7.5 GPa, a graphite furnace assembly was inserted into a pressure medium of semi-sintered MgO in the shape of an octahedron with an 18-mm edge length. Above 7.5 GPa, $LaCrO_3$ was used as the furnace element in a 14-mm-edge octahedron of MgO (Fig. 1*a*). Temperatures were monitored with W–Re thermocouples and have uncertainties of

±50 °C due to the temperature gradient within the furnaces[17]. Pressures were calibrated at several fixed points at room temperature [Bi(I–II), Bi(III–V) and Pb(I–II)] and at high temperatures (quartz–coesite, fayalite–γ spinel, coesite–stishovite and forsterite–β spinel). Uncertainties in pressures are estimated to be <0.05 GPa up to 3 GPa, and 0.5 GPa above 3 GPa. Experiments above 5 GPa were typically 10 min in duration.

Figure 2 shows the solidus and liquidus curves for KLB-1. At 1 atm the partial melt region is ~600 °C, whereas it contracts to ~100 °C at 10 GPa as predicted by Herzberg[18]. Olivine is in the liquidus phase at all pressures. The second liquidus phase, however, changes with increasing pressure: chromian spinel (1 atm), Ca-poor orthopyroxene (0.5–3 GPa), pigeonitic clinopyroxene (3–5 GPa) and pyrope-rich garnet (5–11 GPa). Figure 1*b* shows the distribution of melt coexisting with olivine and garnet in an experiment at 7.5 GPa and 1,900 °C. The melt is confined to small isolated pockets in triple junctions between the crystals. Figure 1*c* shows melt, which has segregated from the matrix, coexisting with olivine only at 5 GPa and 1,800 °C. In experiments using the split-sphere type apparatus, segregation of the partial melts during short runs was probably due to the thermal gradient and/or stress gradient in the furnace assemblies.

The chemical compositions of partial melts formed within 50 °C of the dry solidus are shown in Table 1. To avoid the modification of melt compositions, during quenching[5,19], only segregated partial melts were chemically analysed. Because high-MgO melts do not quench to a glass, but crystallize with well-developed spinifex textures (Fig. 1*c*), a defocused electron beam was used for their analysis and the compositions of quench crystals in an area >100 μm were averaged. The melts become increasingly MgO-rich or olivine-normative as pressure increases, and all melts formed above 5 GPa may be classified as peridotitic komatiite in terms of their high MgO content and the chondrite-like abundance of CaO and Al_2O_3 (refs 20, 21). Melts near the solidus at ~5 GPa contain ~30 wt% MgO and are very close to the primary komatiite magma composition estimated by Arndt *et al.*[22] (Table 1).

Preliminary results for PHN1611 are similar, although because of lower MgO/FeO and higher $Na_2O + K_2O$ content, the solidus is displaced to slightly lower temperatures. When compared at the same pressure (P) and temperature (T), partial melts from PHN1611 are enriched in FeO and higher in CaO/Al_2O_3 than those from KLB-1 (Table 1).

The origin of komatiite magmas has been discussed by several authors[6,20–28]. Komatiite has an unusually high liquidus temperature (>1,650 °C)[23] at 1 atm and at low pressures. A very high degree of partial melting (50–70%) of peridotite is required to form a komatiitic liquid[6,21,23]. Both theoretical[29,30] and experimental observation[25] indicate, however, that partial melt will segregate from the peridotite matrix instantly when the degree of partial melting exceeds a critical value which lies between 10 and 30 vol.%. Thus, it is unlikely in static conditions that a very high degree of partial melting can be achieved within the Earth.

A multistage melting model has been proposed by Arndt[25] in which komatiitic magma is formed in a rising diapir after several cycles of partial melting and melt extraction. The possibility of catastrophic magma genesis induced by impacts of large meteorite bodies has also been proposed[24]. Furthermore, a deep-seated magma ocean in the Archaean mantle has been invoked[26] to explain komatiite petrogenesis.

On the basis of the present experimental results, we propose a simple model (Fig. 3) for the derivation of komatiite magma by partial melting of a rising peridotite diapir as it intersects the mantle solidus at a depth of 150–200 km (path A–B). Because initial melts at these depths have komatiitic compositions, it is possible that komatiitic melts segregate and ascend to the surface (path B–C) before the degree of partial melting of the source region reaches a high percentage. Similar models have been proposed for the genesis of picritic (path D–E–F) and basaltic (path G–H–I) magmas at shallower depths[3] and the possibility of komatiite magma generation by partial melting of garnet peridotite at very high pressures (>5 GPa) has already been proposed[27,28].

Because melts of komatiite composition are among the highest temperature magmas known, they may be derived from the deepest levels of magma generation. These depths may be limited

Table 1 Chemical compositions of the starting materials and partial melts

	Starting materials			Peridotite partial melts						Average peridotitic komatiites

by the density crossover between komatiite melts and coexisitng residual mantle solids[28,29]. Komatiite magmas are not common in the Phanerozoic[21], presumably either because the temperature in the Archaean upper mantle was higher than in more recent geological time, or because diapirs originated from greater depths in the Archaean.

This work was supported by grants 58460042 and 59540525 from the Ministry of Education, Science and Culture of Japan. C.M.S. acknowledges financial support through a fellowship from the Japan Society for the Promotion of Science. A sample of PHN1611 was supplied by Dr F. R. Boyd of the Geophysical Laboratory, Carnegie Institution of Washington. Critical comments on the manuscript by Professors I. Kushiro, T. Fujii and C. T. Herzberg were greatly appreciated. The Institute for Study of the Earth's Interior was formerly the Institute for Thermal Spring Research.

Preparation and catalytic properties of ionic sodium clusters in zeolites

Luc R. M. Martens, Piet J. Grobet & Peter A. Jacobs

Laboratorium Oppervlaktechemie, K. U. Leuven, B-3030 Leuven (Heverlee), Belgium

Exposure of high-alumina zeolites to sodium metal vapour produces coloured centres[1–5] which have been associated with the formation of ionic sodium clusters, located in the zeolite cages. To form these centres, excess alkali metal is required, which contaminates the reaction vessel and makes the system unsuitable as a heterogeneous catalyst. The pioneering work of Pines[6] in the area of basic catalysis on sodium metal deposited on alumina implies that ionic clusters in zeolites should exhibit interesting catalytic properties, but there have been no reports of such activity because the procedure yields a material which is difficult to reproduce. Here we present a new method for the preparation of such clusters in zeolites, consisting of the impregnation of a dehydrated zeolite with alcoholic solutions of sodium azide, followed by the controlled decomposition of the azide. As demonstrated by electron-spin resonance (ESR) spectroscopy, ionic sodium clusters are formed in the zeolite pores. These clusters exhibit catalytic properties in both isomerization and hydrogenation reactions of alkenes and alkynes. We believe that this represents the first realistic method for the preparation of alkali metal clusters in zeolites as well as the first catalytic characterization of such systems.

In the present experiments we set out to develop a reliable method for the preparation of ionic sodium clusters in zeolites and to determine the catalytic properties of such material. The preparation method followed Fejes *et al.*[7–9] who reported that the residual acidity of Y zeolites, existing after cation exchange with Na^+ ions, could be neutralized on heating a physical mixture of the zeolite with small amounts of sodium azide (amounts up to 1.12 mmol of NaN_3 per g of zeolite Y were used). We found, however, that when increasing quantities of this product are impregnated on the zeolites A, X and Y using the specific procedure outlined below, this zeolite is turned gradually into a very efficient basic heterogeneous catalyst.

Typically, to 1 g of NaY zeolite present in the form of powder or as 0.8–1-mm agglomerates, and dried at 723 K under a flow of inert gas, was added under inert atmosphere a slurry containing 3.85 mmol of sodium azide and 9.12 mmol of methanol. The volume of this slurry is just sufficient to fill the zeolite pore volume. This wet cake was transferred to an ESR cell or a tubular flow reactor. The water-free cake was first activated *in situ* at a temperature of 523 K and then at 673 K, while the system was continuously purged with an inert gas. In the tubular reactor, the following catalytic conversions were followed: geometrical and double-bond isomerization of *cis*-2-butene and hydrogenation of acetylene, benzene and *cis*-2-butene. The ratio of the product isomers in the isomerization of *cis*-2-butene can be used as a criterion to determine whether the reaction is acid or base-catalysed[6,10–14].

Figure 1*A* illustrates how the isomerization activity of NaY first declines on addition and decomposition of increasing amounts of NaN_3, and then increases. When an average of eight molecules of NaN_3 are impregnated per supercage of zeolite (3.85 mmol per g of zeolite Y), an activity pattern with two maxima is obtained (Fig. 1*B*). The catalysts with an activity maximum at low temperature have a bright-red colour and exhibit an ESR spectrum having 13 lines with $g = 2.003$ and $a = 3.35 \pm 0.10$ mT (Fig. 2*A*). This spectrum has been ascribed to an ionic Na_4^{3+} cluster[2]. The cluster signal is accompanied by a single broad line at $g = 2.078$. This signal has not been reported in previous work and is, for the moment, assigned to large alkali metal particles located in the zeolite supercages or at the outer surfaces of the zeolite crystals. On thermal sintering, a single line at $g = 2.003$ appears (Fig. 2*B*); this signal is close to that

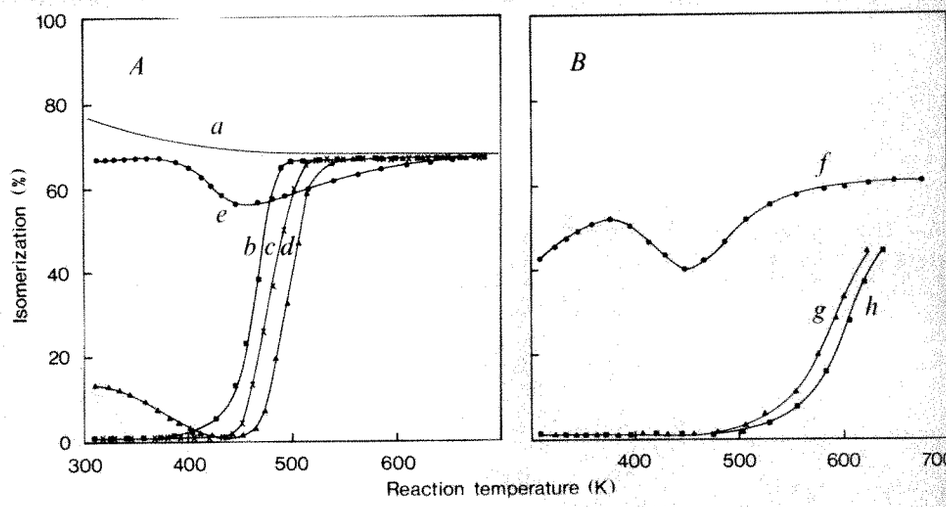

Fig. 1 Isomerization of *cis*-2-butene over dehydrated NaY zeolites: *A*, impregnated with increasing amounts of NaN_3, using a volume hourly space velocity (VHSV) of 36, and *B*, impregnated with 3.85 mmol of azide per g of zeolite at a VHSV of 100. *a*, The thermodynamically expected equilibrium conversion; *b*, the isomerization activity of the parent NaY and its activity after addition of *c*, 1.54; *d*, 2.88; and *e* or *f*, 3.85 mmol of azide per g of zeolite; *g*, after thermal treatment of *f* at 700 K; *h*, after treatment of *f* with oxygen at room temperature and heating in an inert atmosphere at 673 K.

reported for bulk metal[5]. Extended sintering ultimately causes the disappearance of the signal ascribed to the ionic cluster. During this treatment, the broad line at $g = 2.078$ is unaffected while the isomerization activity varies in parallel with the intensity of the signal, ascribed to the existence of the ionic cluster. On exposure to oxygen of the red catalyst (at room temperature) its colour, low-temperature catalytic activity and the 13-line ESR spectrum vanish instantly. The disappearance of the other ESR signals requires longer exposure times.

The initial 1- to *trans*-2-butene product ratios from *cis*-2-butene at low conversions are given in Table 1. The values of these ratios increase in parallel with the amount of NaN_3 added to zeolite Y. If the initial 1-butene to *trans*-2-butene ratios are >2, the *cis*-2-butene isomerization is catalysed by basic sites[6,10–14]. This behaviour confirms that on addition of increasing amounts of NaN_3 to NaY zeolite, residual acidity first has to be neutralized and eventually basic catalytic centres form. We associate this high base-catalysed activity with the presence of the ionic sodium clusters. The residual activity observed after exposure of the catalyst to oxygen is associated with the sodium metal particles located either in the supercages of the Y zeolite or at the external surface of the zeolite crystals. The presence of ionic clusters, as evidenced by the 13-line ESR spectrum and the high catalytic activity, is extremely sensitive to the presence of residual oxygen and water molecules. Therefore, the catalytic sites are definitely sodium clusters and not sodium oxide or hydroxide species which are dispersed in the zeolite cages.

The 13-line ESR spectrum was observed by Harrison *et al.*[5] only for zeolites containing sodalite units on exposure to sodium

Table 2 Hydrogenation activity of NaY zeolites containing initially 3.85 mmol NaN_3 per g of zeolite

Reaction	VHSV	Reaction temperature (K)	% Conversion
Hydrogenation butenes	125	348	36
Hydrogenation acetylene	80	343	10
Hydrogenation benzene	76	345	0

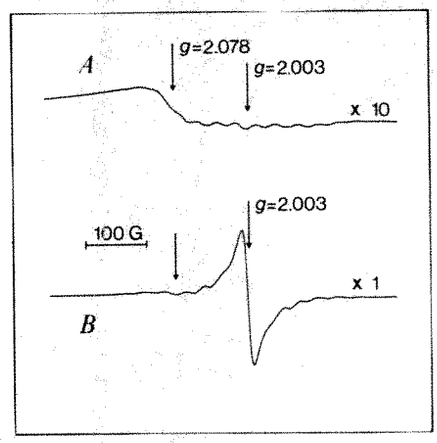

Fig. 2 ESR signals from dehydrated NaY after impregnation with 3.85 mmol NaN_3 per g of zeolite and after subsequent thermal activation (*A*) or after sintering of *A* in an inert atmosphere at 673 K (*B*).

metal. They concluded, therefore, that the sodium ionic clusters are located in the hidden cages of these zeolites. At this stage, it is not clear how electron transfer from the hidden ionic clusters to the butene molecules occurs, or how this view can be reconciled with the high catalytic activity, but we have ample evidence that the high-base catalysed activity in the butene isomerization appears in parallel with these ionic clusters.

Table 2 shows that the catalysts containing ionic clusters are also able to hydrogenate butene and acetylene at non-negligible rates, while benzene in the same conditions cannot be hydrogenated. Peculiar properties of these catalysts are: (1) 50% of the products obtained from *cis*-2-butene, are saturated (butane); the other 50% are feed isomers. This indicates that hydrogenation as well as isomerization occurs at comparable rates. (2) Hydrogenation of acetylene on these basic centres is highly selective as the ethylene/ethylene + ethane ratio is close to 85%.

When the NaN_3 method is used with zeolite X, an intense blue colour, a 19-line ESR spectrum associated with a Na_6^{5+} cluster[1] and a pronounced low-temperature catalytic activity is found. To a minor extent, this is also true for zeolite A, while with other zeolite supports such as Na-ZSM-5 and mordenite, no colour is observed, nor is an ESR signal with $g = 2.003$ detected. Such samples also show no low-temperature basic activity.

In this respect, we have been unable to reproduce the catalytic activity of mordenite containing only Na^+ ions in hydrogenation reactions, as reported by Minachev[15]. These results confirm that either the ionic clusters are stabilized in the sodalite cages as suggested by Harrison *et al.*[5], or they are not formed in high-silica zeolites, so the virtue of A, X and Y zeolites may be the close

presence of several acid sites, due to the low Si/Al ratio, which can form a suitable counterion to the ionic cluster Na_4^{3+}. In view of the latter possibility, it is no longer necessary to assume the presence of such clusters in hidden locations and direct contact of the reacting hydrocarbons is possible with these clusters.

We have shown that on impregnation of appropriate quantities of NaN_3 into the high-alumina zeolites A, X and Y, and on its subsequent thermal decomposition in the specific conditions described, ionic sodium clusters are formed which exhibit typical basic catalytic properties at low reaction temperatures.

L.M. thanks NFWO-FNRS for a research grant, while P.G. and P.J. acknowledge a research position from the same institution. The present research is carried out in the frame of a concerted action on catalysis sponsored by the Belgian Government.

Novel pathway connecting the outer and inner vertebrate retina

Hiroko Sakai & Ken-Ichi Naka

National Institute for Basic Biology, Okazaki 444, Japan

In many fish retinas, thin axons from the external horizontal cells extend through the inner nuclear layer and expand into large terminal processes that lie along the border of the inner nuclear and inner plexiform layers[1]. Although the horizontal-cell axon terminals are structurally very prominent, their function is unknown[2]. Here we report morphological and functional evidence that signals from catfish (*Ictalurus punctatus*) horizontal-cell axon terminals can be transmitted directly to amacrine cells. Current injected into horizontal-cell axon terminals produces responses from both transient and sustained amacrine cells very similar to those elicited by light stimuli. Electron microscope observations show chemical synapses from the axon terminals onto amacrine cell perikarya and processes. These data suggest that amacrine cells in the catfish retina receive two inputs, one from bipolar cells and the other from horizontal-cell axon terminals.

For electron microscopy, standard fixation and staining procedures were used[3]. Fourteen sets of serial sections (200-400 sections per set) from five retinas were examined. The horizontal-cell axon terminals are easily recognized in the electron microscope because of their size and the abundance of microtubules[4]. We observed typical chemical synapses made by the terminals onto postsynaptic elements in the inner nuclear layer and along the border of the inner plexiform layer. Approximately two-thirds of the postsynaptic elements were identified as amacrine cell processes or perikarya because they contained pale cytoplasm and scattered synaptic vesicles and, occasionally, made conventional synapses. Furthermore, serial section tracing did not reveal any synaptic ribbons in the postsynaptic elements, or processes associated with these elements which extended towards the outer plexiform layer. Figure 1 shows an example of a horizontal-cell axon terminal synapsing onto the cell body of a presumed amacrine cell in the inner nuclear layer. The synapse is characterized by an aggregation of round synaptic vesicles associated with increased density on both the pre- and postsynaptic membranes. A subsurface cistern frequently occurred along the postsynaptic site. One such synapse was found, on average, in each 60-μm^2 area of contact made by the horizontal-cell axon membrane with the amacrine cell perikarya and elements in the inner plexiform layer. We have so far observed a total of 18 such contacts, 2 on cell perikarya and 16 on processes.

For physiological experiments, extrinsic current was injected into horizontal-cell axon terminals in the eyecup preparation while recordings were made from amacrine cells. Two intracellular electrodes with tips separated by ~0.4 mm were used; one electrode injected current into the horizontal cells while the other recorded responses from amacrine cells. In the catfish retina only one type of horizontal cell receiving inputs from cones has been reported; its perikaryal response shows a monophasic receptive field of ~0.5 mm in halfwidth and its axon-terminal response shows a receptive field with a halfwidth of ~1 mm (refs 5, 6). This difference in receptive-field size, which may be demonstrated by either a travelling or random bar of light[6], enabled us to identify unambiguously the site of recording. Two types of amacrine cell response can be identified in the catfish retina; one type produces a sustained response and is referred to as sustained or type-N amacrine cell and the other produces a transient response and is termed transient or type-C amacrine cell[7-9].

We performed current injection experiments in six retinas and observed that current injected into the horizontal-cell axon terminals always produced responses in both the transient (15 pairs) and sustained (15 pairs) types of amacrine cells[8-10]. Examples are shown in Fig. 2 in which responses from both types of cells were produced by both light and current injected into the horizontal-cell axon terminal. Records *a* and *b* were from a depolarizing sustained (type-NA) amacrine cell

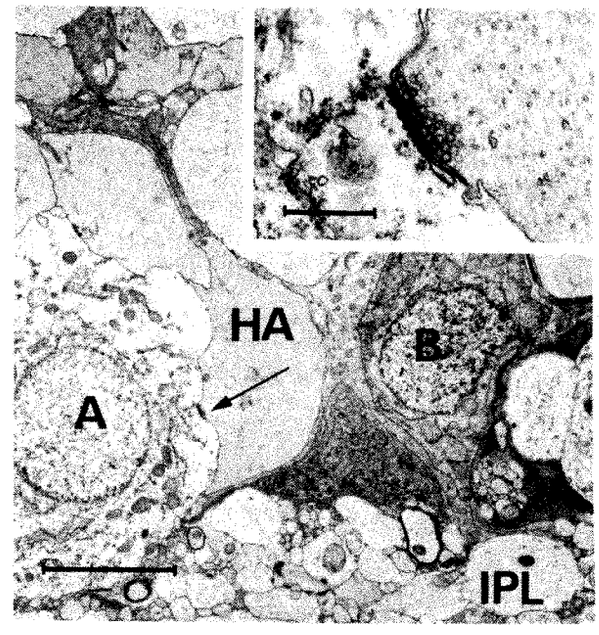

Fig. 1 Electron micrograph of cross-section of a catfish retina showing a synapse from a horizontal-cell axon onto the amacrine-cell perikaryon. Arrow, synapse; A, amacrine cell; HA, horizontal-cell axon; B, bipolar cell; IPL, inner plexiform layer. Scale bar, 5 μm. Inset, high magnification of the synapse indicated by the arrow. Scale bar, 0.5 μm.

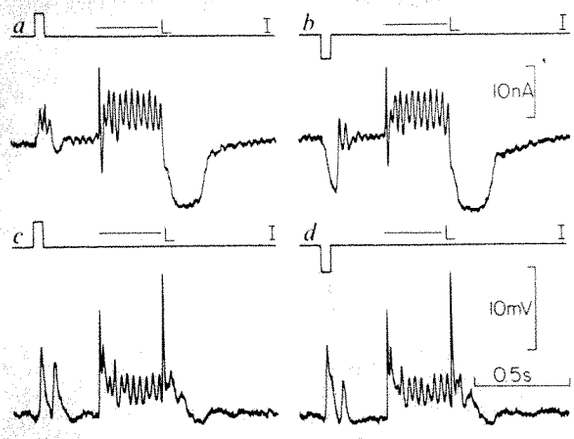

Fig. 2 Responses recorded from sustained or type-N (*a*,*b*) and transient or type-C (*c*,*d*) amacrine cells. The responses are typical of catfish amacrine cells as reported previously[7,8]. Responses were evoked by a current (I) pulse followed by a light flash, the approximate timing of which is shown by the bar marked L. Quantitative analyses of latency of current or light responses have been described elsewhere[6]. The type-N cell shown is the depolarizing variant (type NA) but current injected into the horizontal-cell axon produced similar responses (with the polarity of slow potential reversed) from the hyperpolarizing variants (type NB). Note that, in the type-N cell, the polarity of the current-induced slow potentials reversed when the polarity of current was reversed. Oscillations were superposed on the depolarizing phase of the response. Some type-C cells produced oscillations as seen in *c*, *d*, but some did not. Calibrations apply to all records.

whose light-evoked responses were characterized by an initial depolarizing transient followed by oscillatory wavelets. There was also a very large afterhyperpolarization at the cessation of illumination. A depolarizing current injected into the axon terminal (Fig. 2*a*) also produced a depolarizing response on which a few oscillatory wavelets were seen, whereas a hyperpolarizing current (Fig. 2*b*) produced a hyperpolarizing response with wavelets seen on the off-depolarization. Light-evoked responses from a transient (type-C) cell are shown in Fig. 2*c*, *d*. Illumination elicited large on- and off-transient depolarizations with oscillations between, whereas depolarizing (Fig. 2*c*) and hyperpolarizing currents (Fig. 2*d*) both produced on- and off-transient depolarizations.

There are three possible pathways by which the horizontal-cell axon terminals can communicate with amacrine cells: (1) via horizontal-cell perikarya which synapse onto the bipolar cells and then contact amacrine cells; (2) via horizontal-cell axon terminals synapsing onto the bipolar cells which contact amacrine cells; or (3) via synapses directly onto the amacrine cells. The first and second possibilities seem unlikely because: (1) current ($\leq$40 nA) injected into axon terminals failed to evoke a response in bipolar cells (10 pairs), whereas current ($<$10 nA) injected into horizontal-cell perikarya always evoked responses from bipolar cells (32 pairs); (2) current ($\leq$40 nA) injected into the axon terminals produced only very small responses (0.7 mV) in the horizontal-cell perikarya (12 pairs)[6]; and (3) current of $<$10 nA injected into the axon terminals produced responses from the amacrine cells (Fig. 2). Furthermore, axon terminals have not been observed to synapse onto the bipolar cells in catfish, whereas synapses made by the axon terminals onto the amacrine cells have been found.

We conclude that there are two independent pathways for signal transmission from the outer to inner plexiform layers in the catfish retina. One is the established pathway through bipolar cells and the other is a new pathway through the horizontal-cell axon terminals. Two recent anatomical studies have also identified synapses made by horizontal-cell axonal processes in goldfish (ref. 11 and D. W. Marshak and J. E. Dowling, personal communication); hence such a synaptic pathway may not be unique to the catfish.

Note that the current-evoked responses elicited in the amacrine cells have similar characteristics to those of the light-evoked responses, showing that complex responses such as oscillations in the type-N cell and transient depolarizations in the type-C cell are produced when signals are transmitted directly from the axon terminals to the amacrine cells. This suggests that the complex responses of amacrine cells reflect intrinsic properties of the cell and not the properties of the specialized bipolar–amacrine cell synapses.

We thank John E. Dowling for his comments on the manuscript. Part of this research was supported by NIH grant EY-10897.

Acetylcholine receptor-aggregating factor is similar to molecules concentrated at neuromuscular junctions

Justin R. Fallon, Ralph M. Nitkin, Noreen E. Reist, Bruce G. Wallace & U. J. McMahan

Department of Neurobiology, Stanford University School of Medicine, Stanford, California 94305, USA

The basal lamina in the synaptic cleft of the vertebrate skeletal neuromuscular junction contains molecules that direct the formation of synaptic specializations in regenerating axons and muscle fibres[1–4]. We have undertaken a series of experiments aimed at identifying and characterizing the molecules responsible for the formation of one of these specializations, the aggregates of acetylcholine receptors (AChRs) in the muscle fibre plasma membrane. We began by preparing an insoluble, basal lamina-containing fraction from *Torpedo californica* electric organ, a tissue which has a far higher concentration of cholinergic synapses than muscle, and showing that this fraction caused AChRs on cultured chick myotubes to aggregate[5–7]. A critical step is learning whether or not the electric organ factor is similar to the receptor-aggregating molecule in the basal lamina at the neuromuscular junction. The importance of this problem is emphasized by reports that clearly non-physiological agents, such as positively charged latex beads[8], can cause AChR aggregation on cultured muscle cells. We have already shown that *Torpedo* muscle contains an AChR-aggregating factor similar to that of electric organ, although in much lower amounts[6]. Here we demonstrate, using monoclonal antibodies, that the AChR-aggregating factor in our extracts of electric organ is, in fact, antigenically related to molecules concentrated in the synaptic cleft at the neuromuscular junction.

A mouse was injected with 300 μg of an electric organ extract enriched >1,000-fold in AChR-aggregating activity[7] and hybridomas were generated by standard procedures (see Table 1 legend). To identify hybridomas that produced antibodies against electric organ material, we used indirect immunofluorescence histochemistry and screened for antibodies that bound to formaldehyde-fixed frozen sections of electric organ. We then tested the antibodies that stained electric organ for those that could immunoprecipitate the AChR-aggregating activity from our electric organ extract. Thus far, we have cloned two

hybridomas producing such antibodies. Both antibodies, 6D4 and 2F6, also immunoprecipitated the activity in muscle extracts and blocked AChR aggregation when added to myotube cultures together with either muscle or electric organ extract (Table 1).

To determine the distribution of muscle antigens recognized by 6D4 and 2F6, formaldehyde-fixed frozen sections of *Torpedo* skeletal muscle were examined by immunofluorescence histochemistry. Figure 1 shows that 6D4 intensely stained the neuromuscular junctions. Staining was also detected in the walls of arteries and around individual pre-terminal axons, and there were occasional lightly stained patches at the extrajunctional surface of some muscle fibres (not shown). No other structures in muscle were labelled. Thus, the AChR-aggregating factors in our extracts of electric organ and muscle are antigenically related to molecules associated with more than one tissue component of muscle, but on myofibres, such molecules are concentrated at neuromuscular junctions.

Sections of muscle labelled with 2F6 had a staining pattern similar to that of 6D4, suggesting that both monoclonal antibodies bind to the same antigens. However, 2F6 did not stain sections exposed to fixative for longer than 1 min, even at a 100-fold greater concentration than that sufficient to stain ≥ nfixed tissue. Binding of 6D4, on the other hand, was not affected by our routine fixation; the titre required for staining was the same for unfixed sections and sections fixed for 5 min. Thus, 6D4 and 2F6 recognize epitopes which can be distinguished from one another by their sensitivity to fixation.

We are now performing experiments to determine whether antigens recognized by 6D4 and 2F6 at the neuromuscular junction are components of the synaptic basal lamina. As a first step, we checked the distribution of basal lamina in *Torpedo* muscle by staining cross-sections with an antiserum[9] against laminin, a common constituent of basal lamina sheaths. As expected, basal lamina envelops the same structures in *Torpedo* muscle as in mammalian muscle[10], including muscle fibres, arteries, capillaries, veins, perineurium and Schwann cells (which surround axons). Thus, 6D4 and 2F6 do not stain all structures that have basal lamina, but basal lamina is associated with all structures stained by these antibodies. To determine whether or not epitopes recognized by 6D4 are extracellular, muscles were fixed, incubated with the antibody and examined in whole mounts by immunohistochemistry. The plasma membranes remained intact during these procedures; thus, the antibodies could interact only with the extracellular matrix and the external surface of plasma membranes. Fluorescence microscopy revealed that all the structures labelled in cross-sections were also stained in the whole mounts, including neuromuscular junctions (Fig. 1*c*). Some whole-muscle preparations incubated with 6D4 and a horseradish peroxidase (HRP)-conjugated second antibody were examined by electron microscopy to determine the distribution of 6D4 epitopes at neuromuscular junctions. Figure 1*d* demonstrates that HRP reaction product occupied much of the synaptic cleft, including the synaptic portion of the myofibre basal lamina; no labelling was detected beyond the synaptic cleft. Thus, epitopes recognized by 6D4 at neuromuscular junctions are concentrated in the synaptic cleft and are a part of or adjacent to the synaptic basal lamina.

Extracts that cause AChR aggregation on cultured myotubes have been obtained by others from neurone cultures[11] and neurone-rich tissues including brain, spinal cord and peripheral nerves[12–17]. None of the active factors in these extracts has been shown to be related to molecules concentrated at the neuromuscular junction or any other synapse, as we demonstrate here for the AChR-aggregating factor from *Torpedo* electric organ.

It is possible that the electric organ AChR-aggregating factor is related to a known component of the basal lamina at the neuromuscular junction. Such components include acetylcholinesterase[18], a heparan sulphate proteoglycan[19], and one or more uncharacterized antigens[20], all of which are either absent from, or in much lower concentrations in, extrajunctional regions of the myofibre basal lamina sheaths. The ability of these molecules to cause receptor aggregation has not been tested. Other components of synaptic basal lamina, including type IV collagen, fibronectin and laminin, are common to synaptic and extrasynaptic basal lamina[10]. Of these shared components, only laminin causes AChR aggregation when applied to cultured myotubes[21]. As reported previously, gel filtration of our solubilized electric organ material did not reveal any AChR-aggregating activity in the size range of laminin (relative molecular mass 880,000)[9]; most of the activity eluted at a position characteristic of proteins of lower relative molecular mass (50,000–100,000)[7]. Moreover, as illustrated in Table 2, antiserum against laminin, which stained basal lamina in our sections of *Torpedo* muscle, did not immunoprecipitate AChR-aggregating activity from electric organ extracts. These observations, coupled

Table 1 Monoclonal antibodies block and immunoprecipitate AChR-aggregating activity in extracts of electric organ and muscle

Additions	Activity (%) Immunoprecipitation	Blocking
Electric organ extract		
+control	100 ± 12	100 ± 13
+6D4	−5 ± 2	−2 ± 2
+2F6	23 ± 5	9 ± 0
Muscle extract		
+control	100 ± 7	100 ± 29
+6D4	3 ± 4	31 ± 12
+2F6	3 ± 0	18 ± 8

A *p*H 5.5 citrate extract[6] containing 1–1.5 units of AChR-aggregating activity prepared from *Torpedo* electric organ or tail muscle was mixed with 120–200 μl of hybridoma supernatant for 2 h at 37 °C in a volume of 200–465 μl. To determine blocking, aliquots were applied directly to cultured chick myotubes. To determine immunoprecipitation, the mixture was incubated for an additional 0.5–2 h with goat anti-mouse IgG-conjugated Sepharose beads (see ref. 6), centrifuged to remove the bound immune complexes, and aliquots of the supernatant were assayed on cultured myotubes. AChR-aggregating activity was determined by counting the number of patches of AChRs on the myotubes as described previously[6]. Control supernatants were taken from either the parent myeloma or a hybridoma producing antibodies that did not stain electric organ. Each value represents the mean ±s.e.m. of triplicate determinations. Generation of monoclonal antibodies: A female BALB/c mouse was given an intraperitoneal (i.p.) injection of 20 μg of purified electric organ extract[7] emulsified with an equal volume of Freund's complete adjuvant; after 4 weeks, the mouse was injected i.p. with an additional 16 μg of this extract emulsified with Freund's incomplete adjuvant. After 4 more weeks, 260 μg of extract without adjuvant was injected beneath the capsule of the spleen. The spleen was removed 3 days later and the cells were fused with a mouse myeloma cell line, P3X63-Ag8.653, by the procedure of Oi and Herzenberg[23]. Viable hybridomas were found in 500 of the original 572 wells plated. Of these, the supernatant from 105 wells stained sections of electric organ.

Table 2 Antiserum against laminin does not immunoprecipitate AChR-aggregating activity

Additions	Activity (%)
None	100 ± 16
Normal serum (20 μl)	122 ± 13
Antiserum against *p*H 5.5 citrate extract (2 μl)	−5 ± 12
Antiserum against laminin (20 μl)	104 ± 13

An aliquot of a *p*H 5.5 citrate extract[6] containing 1.5 units of AChR-aggregating activity prepared from *Torpedo* electric organ was mixed with the indicated amount of heat-inactivated rabbit serum in a total volume of 70 μl for 2 h at 37 °C. The mixture was incubated for an additional 0.5 h with 10 μg of fixed *Staphylococcus aureus* (Pansorbin [Calbiochem], washed and resuspended in 50 μl of 1 M Tris buffer, *p*H 8.5), then centrifuged to remove bound immune complexes and assayed as described in Table 1 legend. Antiserum against *p*H 5.5 citrate extract[6] was used to confirm the effectiveness of *S. aureus* immunoprecipitation.

with the finding that 6D4 and 2F6 staining co-localized with only a fraction of anti-laminin staining in muscle, indicate that the electric organ AChR-aggregating factor is not laminin. However, the fact that two different monoclonal antibodies against the electric organ AChR-aggregating factor recognize cell-surface antigens in the walls of arteries and in nerves as well as at neuromuscular junctions may mean that the factor is structurally related to one or a family of basal lamina molecules that have a broad distribution in muscle.

Taken together, our studies provide several lines of evidence that the electric organ AChR-aggregating factor is similar to the component of the synaptic basal lamina that directs the accumulation of AChRs on regenerating muscle fibres: the factor is found in an extracellular matrix-rich fraction of the electric

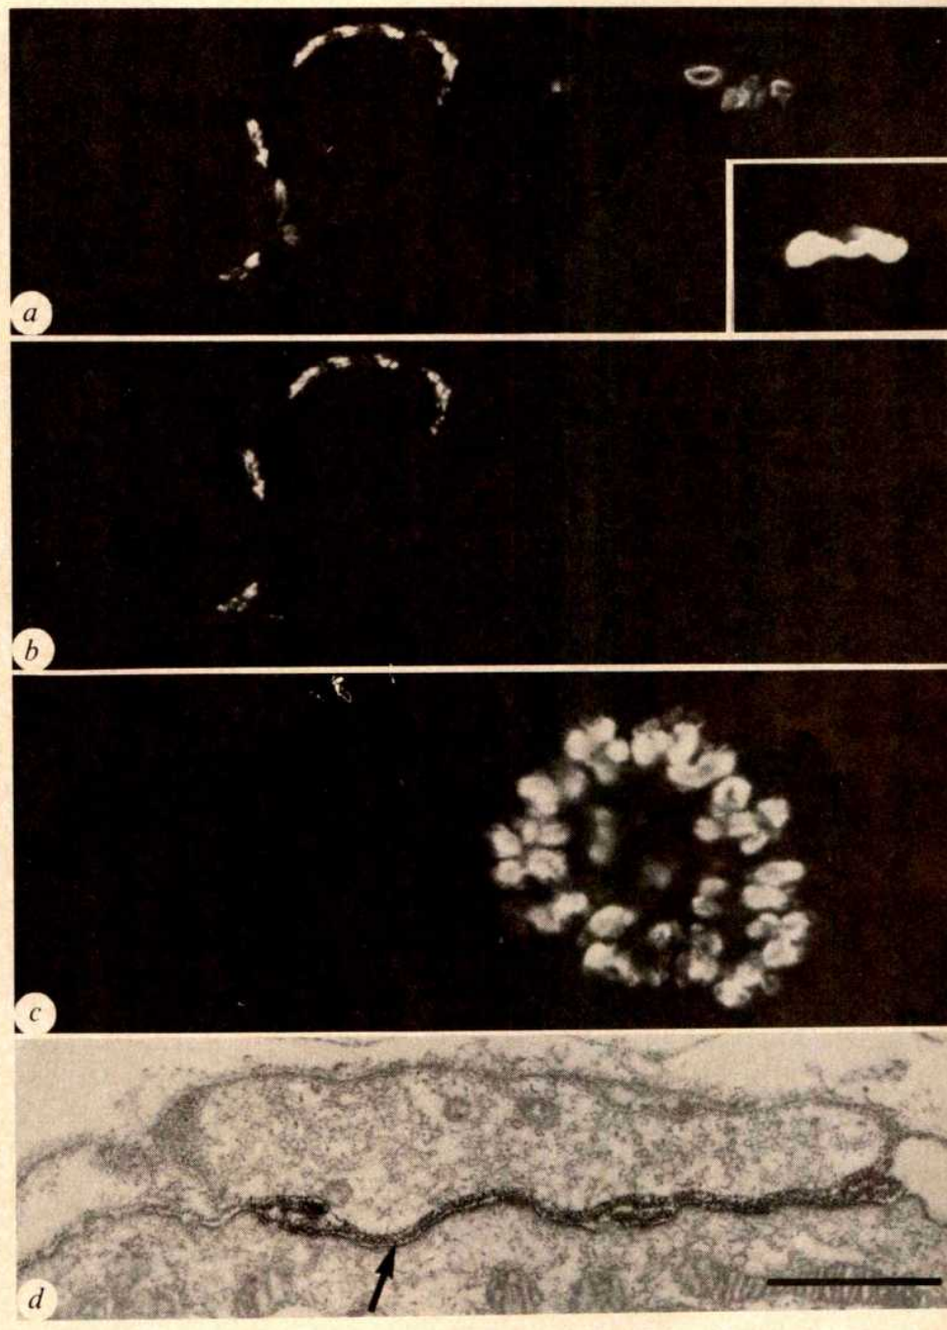

Fig. 1 6D4 binds to antigens concentrated at neuromuscular junctions in skeletal muscle. ***a***, Frozen section of *Torpedo californica* muscle viewed with fluorescein optics to show the position of 6D4-binding sites. ***b***, Same field as in *a* but viewed with rhodamine optics to reveal the location of neuromuscular junctions. 6D4 binding is confined to neuromuscular junctions, the wall of a collapsed artery (inset), and the perimeter of each of several axons. ***c***, A whole-mount of a fascicle of *Torpedo* muscle fibres viewed with fluorescein optics to reveal bound 6D4. A neuromuscular junction, seen from above and similar in layout to that of other vertebrates[24], is intensely stained; preterminal axons are faintly stained. ***d***, Electron micrograph of a neuromuscular junction from a *Discopyge ommata* fin muscle incubated with 6D4 and then with an HRP-conjugated second antibody. Electron-dense HRP reaction product occupies much of the synaptic cleft, including the synaptic portion of the muscle fibre basal lamina (arrow). We used the fin muscles from *D. ommata* (an electric ray like the *Torpedo* but less than one-quarter the size) because they were smaller than any muscles we encountered in *Torpedo* and, thus, were easier to process for electron microscopy. Fluorescence immunohistochemistry on frozen sections and on whole mounts of these muscles revealed the same 6D4 staining pattern as in muscles from *Torpedo*; no 6D4 staining was observed at neuromuscular junctions in frog, salamander and chick muscles. Scale bar: *a*, *b*, 75 μm; *c*, 33 μm; *d*, 1 μm.

Methods. Frozen sections *a*, *b*: sections (8–10 μm thick) of back muscles of *Torpedo* were incubated for 10 min in 10% normal goat serum in phosphate-buffered saline (PBS), washed briefly in PBS, fixed for 5 min in 1% formaldehyde in PBS, washed for 5 min in 0.1% Triton X-100 in PBS (PBS-T), and incubated overnight at 4 °C in 6D4 supernatant diluted 1:200 in PBS containing 20% normal goat serum and 0.5% Triton X-100 (PBS-ST). (The same staining pattern was observed at dilutions of 6D4 supernatant ranging over 1–20,000-fold.) The sections were then washed for 3 h in PBS-T and incubated for 1 h in PBS-ST containing fluorescein-conjugated goat anti-mouse IgG (Cappel) to label bound 6D4 and rhodamine-α-bungarotoxin to stain AChR aggregates at neuromuscular junctions. Coverslips were mounted with Citifluor mountant medium AF1 (City University, London). Whole mounts (*c*): Abdominal muscles bathed in *Torpedo* Ringer's[25] were dissected down to single fascicles three to five muscle fibres thick. The muscles were then fixed for 1 h with 1% paraformaldehyde in Ringer's solution, incubated overnight at 4 °C in 6D4 supernatant diluted 1:200 with 0.3 M sodium phosphate buffer *p*H 7.1 (PB), washed for 8 h with several changes of PB, incubated overnight in fluorescein-conjugated goat anti-mouse IgG (Cappel) diluted 1:800 with PB, washed for 3 h in phosphate buffer with 0.1% Triton X-100 (PB-T), refixed for 0.5 h in 1% paraformaldehyde, washed for 2 h with PB-T, and mounted with mountant medium AF1 between glass coverslips. Electron microscopy (*d*): Muscles were pinned out in Ringer's solution, incubated for 3 h in 6D4 diluted 1:50 with Ringer's solution, washed for 45 min with Ringer's, incubated in Ringer's containing HRP-conjugated goat anti-mouse IgG (Cappel), washed for 45 min in PB, fixed for 30 min in 1% glutaraldehyde in PB, washed for 30 min with 0.25 M cacodylate buffer *p*H 7.1, incubated for 30 min in 0.05% 3,3-diaminobenzidine (Sigma) and 0.02% H_2O_2 in cacodylate buffer, washed for 30 min in cacodylate buffer, immersed for 1 h in 1% osmium tetroxide in PB, dehydrated with ethanol and embedded whole in a mixture of Epon and Araldite[3].

organ[6]; the corresponding fraction of *Torpedo* muscle contains a similar activity[6]; antiserum against partially purified electric organ factor blocks and immunoprecipitates AChR-aggregating activity from muscle and stains muscle basal lamina[7]; as demonstrated here, two monoclonal antibodies recognizing different epitopes block and immunoprecipitate the active component in extracts of both electric organ and muscle and bind in high concentration at the neuromuscular junction; and, at least one of the monoclonal antibodies recognizes molecules that are in or adjacent to synaptic basal lamina. Thus, monoclonal antibodies against the electric organ AChR-aggregating factor, such as 6D4 and 2F6, may be useful reagents for identifying and purifying the components of synaptic basal lamina that direct the aggregation of AChRs on regenerating myofibres, for studying their mechanism of action, for learning how they are regulated and for determining whether they also direct the formation of receptor aggregates in developing muscles or the maintenance of such aggregates in normal adult muscles. It is now known that synaptic basal lamina directs the aggregation of acetylcholinesterase as well as that of AChRs in regenerating muscle[4]. As described in the following report[22], 6D4 and 2F6 have been used to provide evidence that the electric organ factor which causes AChR aggregation also causes the accumulation of acetylcholinesterase on the surface of cultured myofibres, raising the possibility that a single molecule in the basal lamina directs the differentiation of both of these postsynaptic specializations in regenerating muscle.

We thank R. M. Marshall for technical assistance, Dr Rupert Timpl for supplying the antiserum against laminin, Dr Peter Sargent for use of his cryostat and Dr Regis Kelly for giving us *Discopyge ommata*. R.M.N. was a recipient of a postdoctoral fellowship from the American Heart Association, California Affiliate. The studies were supported by NIH grant NS 14506, and grants from the Muscular Dystrophy Association of America and the Dysautonomia Foundation.

Aggregates of acetylcholinesterase induced by acetylcholine receptor-aggregating factor

Bruce G. Wallace, Ralph M. Nitkin, Noreen E. Reist, Justin R. Fallon, N. Nicole Moayeri & U. J. McMahan

Department of Neurobiology, Stanford School of Medicine, Stanford, California 94305, USA

Basal lamina-rich extracts of *Torpedo californica* electric organ contain a factor that causes acetylcholine receptors (AChRs) on cultured myotubes to aggregate into patches[1-3]. Our previous studies have indicated that the active component of these extracts is similar to the molecules in the basal lamina which direct the aggregation of AChRs in the muscle fibre plasma membrane at regenerating neuromuscular junctions *in vivo*[2,4,5]. Because it can be obtained in large amounts and assayed in controlled conditions in cell culture, the AChR-aggregating factor from electric organ may be especially useful for examining in detail how the postsynaptic apparatus of regenerating muscle is assembled. Here we demonstrate that the electric organ factor causes not only the formation of AChR aggregates on cultured myotubes, but also the formation of patches of acetylcholinesterase (AChE). This finding, together with the observation that basal lamina directs the formation of both AChR and AChE aggregates at regenerating neuromuscular junctions *in vivo*[6], leads us to hypothesize that a single component of the synaptic basal lamina causes the formation of both these synaptic specializations on regenerating myofibres.

First, we investigated whether extracts of *Torpedo* electric organ would affect the distribution of AChE on myotubes. For this, aliquots of a saline- and detergent-insoluble fraction of electric organ[3] were added to 5-day-old chick myotube cultures; this fraction is rich in components of basal lamina and causes AChRs on cultured myotubes to aggregate[3]. After 24 h, treated and control cultures were fixed and stained for cholinesterase (ChE) activity by the histochemical method of Karnovsky[7]. Figure 1*a*, *b* shows that the insoluble fraction caused a marked increase in the number of patches of reaction product on the myotubes. Few patches were seen on myotubes stained in the presence 10^{-5} M eserine (Table 1), indicating that the reaction product was due to cholinesterase activity. Patches were induced when both the culture medium and the insoluble fraction were pretreated with methane sulphonyl fluoride (MSF), an irreversible inhibitor of ChE[8] (Table 1); therefore, the ChE in the patches must have been produced by the myotubes. To determine

Table 1 Histochemically stained patches contain myotube-derived ChE

	Addition	Aggregates per myotube segment
Expt *a*		
Control	None	1.1 ± 0.1
	Eserine	0.5 ± 0.2
Insoluble fraction	None	8.9 ± 0.1
	Eserine	0.9 ± 0.3
Expt *b*		
Control	None	2.1 ± 0.2
	MSF-treated medium	2.1 ± 0.5
Insoluble fraction	None	4.2 ± 0.3
	MSF-treated medium	4.5 ± 1.2

Expt *a*, 40-μl aliquots of a MSF-treated insoluble fraction (6.9 μg) or MSF-treated medium were added to cultures (see Fig. 1 legend for MSF treatment). The cultures were incubated overnight and stained for cholinesterase in the presence or absence of 10^{-5} M eserine. Eserine was added 10 min before the histochemical reaction was begun and was present throughout the 1½-h incubation. Expt *b*, MSF (final concentration, 2 mM) was added to culture medium and the mixture was incubated at room temperature for 1 h. Aliquots of the insoluble fraction, treated with MSF as in *a*, were then added to control cultures and cultures that had been fed with MSF-treated medium. The cultures were incubated overnight and stained for cholinesterase. Data are expressed as mean ±s.e.m. of triplicate determinations.

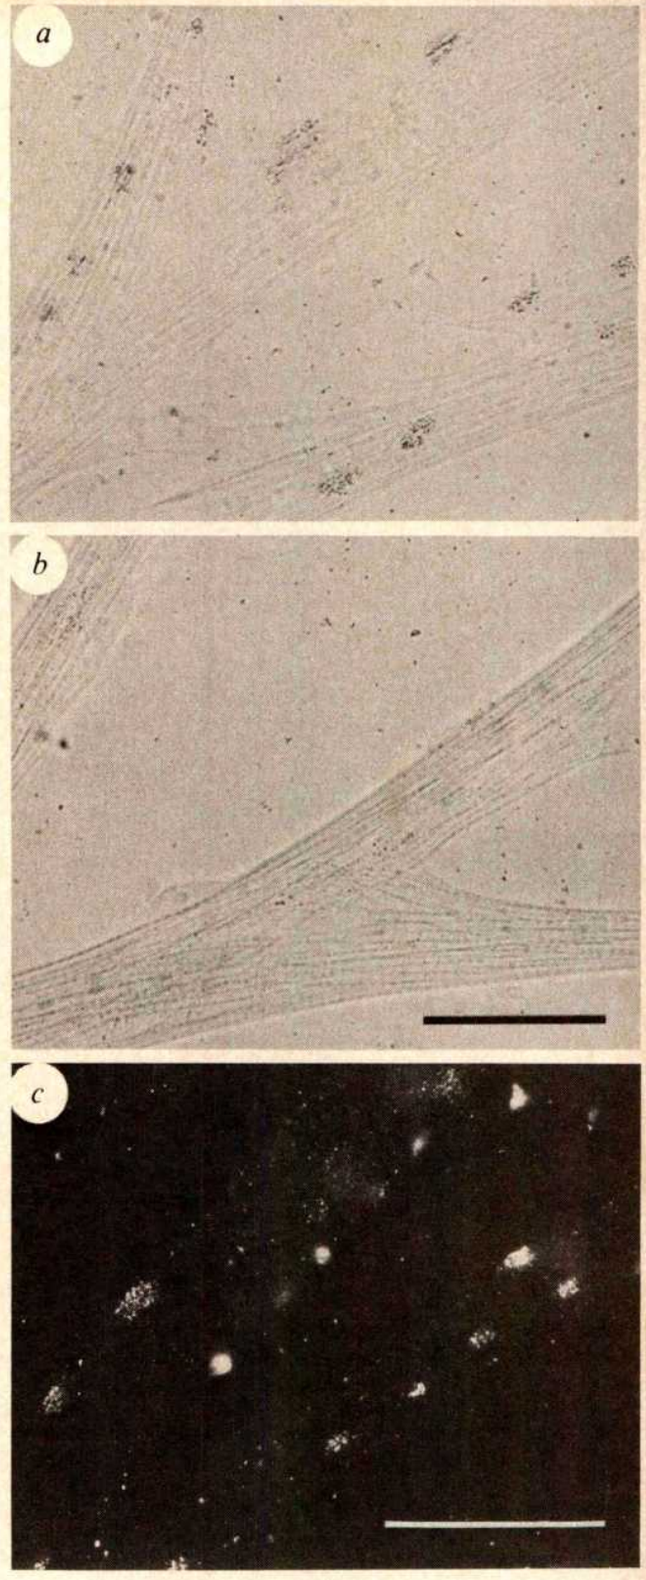

Fig. 1 Formation of AChE aggregates by *Torpedo* electric organ extracts. ***a***, ***b***, Bright-field photographs of 5-day chick myotube cultures[3], incubated for 24 h with medium containing 16 μg of an insoluble fraction of electric organ (*a*) or normal medium (*b*) and stained for ChE activity. ***c***, Fluorescence micrograph of a 5-day culture exposed for 24 h to 45 ng of agarose pool and lablled with anti-AChE and fluorescent second antibody. Scale bars, 50 μm.
Methods. ***a***, ***b***, The cultures were rinsed with buffer containing 150 mM NaCl, 10 mM sodium phosphate, *p*H 7.4 (PBS), fixed for 5 min in 1% paraformaldehyde in 90 mM sodium phosphate, 130 mM sucrose, *p*H 7.4, rinsed with PBS and then reacted for cholinesterase by the method of Karnovsky[7] for 1½ h at room temperature. Cultures were rinsed with 0.1 M sodium maleate, *p*H 6.0, with water, then dehydrated in graded ethanols and mounted in glycerol. Methane sulphonyl fluoride (final concentration 2 mM) was added to the insoluble fraction and the mixture incubated for 1 h at room temperature before adding it to the cultures. The MSF treatment inhibited cholinesterase in the insoluble fraction by >99.8%, as assayed by the method of Ellman *et al.*[26]. The rapid spontaneous hydrolysis of MSF prevented it from inhibiting ChE on the myotubes. ***c***, AChE was labelled with a monoclonal antibody to chick AChE and fluorescent second antibody as follows. Cultures were rinsed with PBS, fixed for 30 min in 1% paraformaldehyde in 90 mM sodium phosphate, 130 mM sucrose, *p*H 7.2, rinsed with PBS and incubated for 1 h at room temperature with a mouse monoclonal antibody specific for chick AChE, 1A2 anti-AChE[9] (6 μg ml^{-1} in PBS supplemented with 10% horse serum). The cultures were then rinsed with PBS, incubated for 1 h with a 1/200 dilution of rhodamine-conjugated goat anti-mouse IgG (Cappel) in PBS + 10% horse serum, rinsed with PBS, dehydrated in graded ethanols and mounted in glycerol. No immunohistochemical staining was seen when cultures were incubated with antibodies secreted by the parent myeloma (not shown).

Table 2 Comparison of ChE histochemistry and AChE immunohistochemistry

	Aggregates per myotube segment	
	ChE histochemistry	Anti-AChE immunohistochemistry
Expt *a*		
Control	3.0 (2.6, 3.4)	3.3 (2.8, 3.8)
Insoluble fraction	6.4 (6.3, 6.6)	5.3 ± 0.6
Expt *b*		
Control	2.0 (1.8, 2.1)	4.8 ± 0.8
*p*H 5.5 extract	6.9 (6.2, 7.6)	10.5 ± 0.8
Expt *c*		
Control	1.6 ± 0.3	1.3 ± 0.2
Agarose pool	7.2 ± 0.7	5.7 ± 0.8

Cultures were treated with the insoluble fraction, *p*H 5.5 extract or agarose pool and either stained for ChE activity or labelled immunohistochemically to reveal AChE (see Fig. 1 legend). Labelled patches on the bottom surface of the myotubes were counted (see Fig. 2 legend). The numbers of patches on 10 myotube segments 400 μm long examined at ×250 magnification were averaged for each culture histochemically. As the patches of rhodamine-labelled anti-AChE were difficult to see at this magnification, antibody-labelled patches were counted at ×400 magnification and the numbers of patches on 20 myotube segments were averaged and multiplied by 1.6. Expts *a*, *b* and *c* were done on different sets of cultures. Data are expressed as the mean of duplicate or triplicate determinations. For experiments done in duplicate, the individual values are given in parentheses; for experiments done in triplicate, the s.e.m. is shown.

whether the patches induced by the electric organ fraction contained true AChE, control cultures and cultures treated with the insoluble fraction were fixed and labelled with a monoclonal antibody specific for chick AChE[9]. The electric organ fraction caused an increase in the number of patches of antibody-labelled AChE on the surface of the myofibres similar to the increase seen with histochemical staining (Fig. 1*c*, Table 2). Because the labelling protocol used for these experiments did not allow antibodies to penetrate plasma membranes, the AChE patches detected must be on the myotube surface. Thus, the insoluble fraction of electric organ causes not only the aggregation of AChRs on cultured myotubes, but also the formation of aggregates of AChE.

We next sought to establish a quantitative assay for AChE-aggregating activity, so that its level could be compared with that of the AChR-aggregating factor. Figure 2 shows that as the amount of the insoluble fraction added to cultures was increased, the number of AChE patches increased and then reached a plateau. Although the magnitude of the response to saturating amounts of the insoluble fraction varied over 2–9-fold from plating to plating, there was little variability in the dose depen-

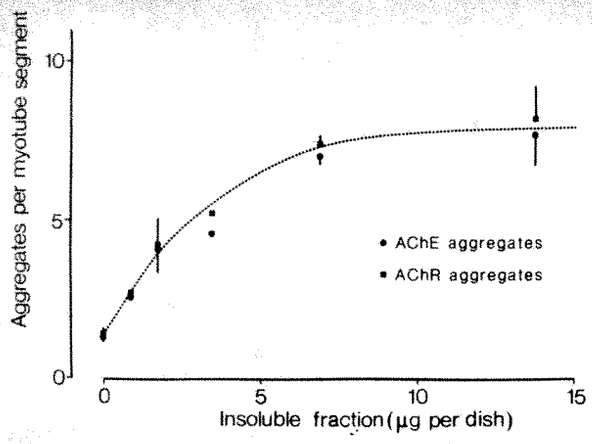

Fig. 2 Dose dependence of the formation of AChR (■) and AChE (●) aggregates on cultured myotubes. Cultures, treated for 24 h with the indicated amount of insoluble fraction, were incubated with 6×10^{-8} M rhodamine-α-bungarotoxin[27] in culture medium for 1 h at 37 °C. The cultures were then rinsed twice with PBS and fixed and reacted for cholinesterase activity as described in Fig. 1 legend. AChR and ChE clusters were counted at ×250 magnification with a Nikon microscope equipped with phase and fluorescence optics. The ChE-stained patches and α-bungarotoxin-labelled AChR clusters were often seen to be partially or totally overlapping; however, there was no indication that the ChE staining ever completely obscured a toxin-labelled AChR aggregate. For each culture, myotubes were chosen at random and the numbers of patches of cholinesterase reaction product along unbranched 400-μm-long segments of the myotubes were counted under phase optics; then the number of AChR clusters was counted under fluorescence optics. Only patches on the bottom of the myotubes were counted because most factor-induced clusters of AChRs and ChE occurred on this surface of the myotube. Counts from 10 myotubes, evenly spaced over the surface of the dish, were averaged. We counted as an aggregate any distinct fluorescent or cholinesterase-stained patch whose longest axis was >2 μm. Data are expressed as the mean ±s.e.m. ($n=3$); error bars are shown where they exceed the size of the data point. To quantitate AChR- and ChE-aggregating activity, curves were drawn through the points by eye (the two curves superimpose in this figure) and one unit of activity was taken as the amount of the fraction required to give a half-maximal response (in this case 2.58 μg per dish).

dence of the response. Thus, by defining one unit of activity as the amount of material required to cause a half-maximal response, AChE-aggregation could be measured reproducibly between experiments.

The dose dependence of the insoluble fraction-induced formation of AChE patches on cultured myofibres was the same as for AChR aggregation (Fig. 2), suggesting that a single factor caused both effects. If this were the case, it should be possible to extract the AChE-aggregating activity from the insoluble fraction and purify it by procedures that solubilize and purify the AChR-aggregating factor. Accordingly, the insoluble fraction was extracted with *p*H 5.5 citrate buffer[3], the solubilized material was fractionated by gel filtration chromatography on agarose[2] and the column fractions causing AChR aggregation were pooled. Both AChR- and AChE-aggregating activities were measured in the insoluble fraction, the *p*H 5.5 extract and the 'agarose pool'. Table 3 shows that the AChR- and AChE-aggregating specific activities were increased to the same extent by extraction and gel filtration chromatography and that the dose dependence for AChR aggregation was the same as that for the formation of AChE aggregates at each step in the purification. (Formation of AChE aggregates was routinely assayed by ChE histochemistry; however, immunohistochemical experiments confirmed that each fraction induced patches that contained true AChE [Table 2]). Thus, AChE- and AChR-aggregating activities co-purify. We also examined whether or not two different monoclonal antibodies, 6D4 and 2F6, directed against the AChR-aggregating factor (see accompanying report[10]), would recognize the AChE-aggregating factor (Table 4). When bound to Sepharose beads, 6D4 and 2F6 each removed AChR- and AChE-aggregating activity from the agarose pool. Moreover, when added directly to cultures together with the agarose pool, 6D4 and 2F6 inhibited the extract-induced formation of both AChR and AChE aggregates. From the observations that (1) the AChR- and AChE-aggregating activities co-purify, (2) the dose dependence for the induction of AChR and AChE aggregates is the same at each stage of the purification and (3) two different monoclonal antibodies immunoprecipitate and inhibit both activities, we conclude that a single factor in our extracts of electric organ causes the formation of AChR and AChE patches.

Table 3 Co-purification of AChE- and AChR-aggregating activities

Fraction	Aggregating activity (units per mg protein) AChR	AChE
Insoluble fraction	374	382
*p*H 5.5 extract	811	952
Agarose pool	49,800	56,200

For each fraction, AChE- and AChR-aggregating activities were measured as described in Fig. 2 legend. The values are the mean of two separate determinations.

Table 4 Immunoprecipitation (*a*) and inhibition (*b*) of AChE- and AChR-aggregating activities

	Addition	Aggregates per myotube segment (% control) AChE	AChR
Expt *a*	Control	100 ± 16	100 ± 15
	6D4	−2 ± 2	−1 ± 4
	2F6	−1 ± 4	7 ± 3
Expt *b*	Control	100 ± 5	100 ± 5
	6D4	2 ± 11	11 ± 4
	2F6	22 ± 4	10 ± 3

Expt *a*: An aliquot of agarose pool (7.2–8.2 units, 134–150 ng) was mixed with 0.3–1.3 ml hybridoma supernatant and incubated for 1½ h at 37 °C. Immunoglobulins and immune complexes were precipitated by adding 30–50 μl of a suspension of goat anti-mouse antibodies covalently coupled to Sepharose beads[3] and 100 μl aliquots of the supernatant were assayed for aggregating activity. Control supernatant was from a hybridoma secreting antibodies of unknown specificity. Expt *b*: An aliquot of agarose pool (6.5–8.2 units, 120–150 ng) was mixed with 0.35–1.3 ml myeloma-conditioned medium or hybridoma supernatant, incubated for 1 h at 37 °C and 0.12–0.4 ml aliquots were assayed for aggregating activity. Data for both experiments, expressed as mean ±s.e.m. ($n=3$), are per cent of maximal response.

AChR and AChE aggregates form part of the postsynaptic apparatus at both normal and regenerated neuromuscular junctions and are the only components of the apparatus known to be directly involved in synaptic transmission. The formation of these cell-surface specializations at developing neuromuscular junctions is induced by the axon terminal[11–13]. On the other hand, in adults, the synaptic portion of the myofibre's sheath of basal lamina can direct the aggregation of AChRs and AChE on regenerating myofibres[4–6]. Thus, the synaptic basal lamina in the adult contains synaptogenic information similar to that provided by the axon in the embryo.

The identity and mechanism of action of the molecules that induce the postsynaptic specializations at developing and regenerating neuromuscular junctions are unknown, although *in vivo* and *in vitro* studies indicate that electromechanical activity of muscle fibres is necessary for the accumulation of high levels of AChE[14–16]. Crude extracts from several neurone-rich tissues such as brain, spinal cord and nerve have been shown to cause AChR aggregation on cultured myotubes, and the active components of some have been partially purified[17–25]. Furthermore, many of the AChR patches formed in response to at least one of the brain extracts are associated with synapse-specific anti-

gens, AChE and invaginations in the myotube plasma membrane which resemble the junctional folds found at normal and regenerating neuromuscular junctions[25]. The results reported here extend the findings of such studies by showing that, in the basal lamina-containing fraction of electric organ, the same factor that causes AChR aggregation also causes the formation of aggregates of AChE. We have also demonstrated (see accompanying report[10]) that two different monoclonal antibodies against this AChR/AChE-aggregating factor bind in high concentration at the neuromuscular junction and that the molecules recognized by at least one of the monoclonal antibodies are in or adjacent to the synaptic basal lamina. Thus, it is reasonable to suggest that the molecules in the synaptic basal lamina which direct the formation of AChR aggregates on regenerating myofibres also cause aggregation of AChE. We are now performing experiments to test this monomolecular induction hypothesis for the formation of AChR and AChE aggregates at both regenerating and developing neuromuscular junctions and to discover whether the electric organ AChR/AChE-aggregating factor causes the formation of other components of the postsynaptic apparatus.

We thank Dr R. Rotundo for providing the monoclonal antibody to chick AChE, and Robert Marshall, Chris Goodwin and Tom Cox for technical assistance. This research was supported by USPHS grant NS14506 and BRSG grant RR 5353.

Inhibition of the Prausnitz–Küstner reaction by an immunoglobulin ε-chain fragment synthesized in *E. coli*

Raif S. Geha*, Birgit Helm† & Hannah Gould†

* Division of Allergy, Children's Hospital and Department of Pediatrics, Harvard Medical School, Boston, Massachusetts 02155, USA
† Department of Biophysics, King's College, London WC2 5RL, UK

The Prausnitz–Küstner (P–K) reaction is a sensitive test for the presence and activity in the skin of immunoglobulin E, an important class of immunoglobulin mediating allergic reactions. A fragment of the human myeloma ND ε-chain gene, encoding the second, third and fourth domains of the IgE constant region (Cε2–4) was assessed here for its ability to inhibit the P–K reaction *in vivo*. Injection of the fragment in skin sites of healthy human adults prevented subsequent sensitization with serum containing IgE antibody to ragweed antigen. Inhibition of the P–K reaction required a 200-fold molar excess of the C_ε fragment over the IgE present in the sensitizing serum. The efficacy of the C_ε fragment in inhibiting the P–K reaction compared favourably with that of natural myeloma IgE (PS) in terms of both blocking concentrations and duration of the blocking effect. The inhibition of the P–K reaction by C_ε2–4 fragments was specific and probably caused by the saturation of IgE receptors on mast cells[1,2] by the recombinant gene product.

The C_ε2-4 gene fragment used encodes amino acids 218–547 of the IgE molecule and was subcloned in *Escherichia coli*, producing a polypeptide of relative molecular mass 40,000[3]. Preparations consisting of >95% affinity-purified C_ε2-4 dimeric chain fragments, when injected into skin sites of a human volunteer, completely blocked the passive sensitization of these sites by serum (E.C.) containing IgE antibody to ragweed antigen (Table 1). This blockade was prevented by treating the C_ε2-4 fragments at 56 °C for 1 h or by reduction and alkylation. Skin sites injected with C_ε2-4 fragments remained normally responsive to histamine (data not shown). More importantly, skin sites sensitized with reaginic serum (E.C.) 1 h before C_ε2-4 fragment injection retained their full ability to support a P-K reaction.

The P-K reaction under study was caused by IgE antibody to ragweed antigen in the sensitizing serum. Heat treatment (56 °C, 1 h) of serum E.C. abolished its ability to sensitize normal skin (data not shown), as would be the case for an IgE antibody[4,5]. Table 2 shows that when an immunoglobulin-enriched fraction of serum E.C. was fractionated over an anti-IgE (PS) Sepharose-4B column, only the IgE-containing eluate, but not the IgE-depleted effluent, was able to induce a P-K reaction. This was blocked by pretreatment of the skin sites with C_ε2-4 fragments.

The P-K reaction induced by a 1:100 dilution of serum E.C. (1:100) containing 5×10^{-11} M IgE was abolished completely

Table 1 Inhibition of Prausnitz-Küstner reaction by C_ε2-4 fragments

	Inhibitor	Area (mm²) of wheal and flare at sites sensitized with Serum E.C. diluted 1:10	Serum E.C. diluted 1:100
Expt 1	Diluent	87/480	42/257
	C_ε2-4 (100 μg ml^{-1})	0/0	0/0
	C_ε2-4 56 °C 1 h (100 μg ml^{-1})	76/455	38/271
Expt 2	Diluent	103/516	54/268
	C_ε2-4 (10 μg ml^{-1})	0/0	0/0
	C_ε2-4 (10 μg ml^{-1}) reduced, alkylated	92/472	44/240

Values are the areas of the wheal/the area of the flare. Reduction and alkylation were performed as described in ref. 3. The same subject was used for passive sensitization in both experiments; the serum IgE of this subject was 4 IU ml^{-1} (~10 ng ml^{-1}). The sensitizing serum (E.C.) contained 380 IU ml^{-1} of IgE (~912 ng ml^{-1}), of which 8.7% was directed against ragweed antigen, as determined by the specific drop in serum IgE following absorption of the serum over a Sepharose 4B ragweed antigen column compared with a control Sepharose 4B human serum albumin[7]. Serum E.C. was free of detectable hepatitis B antigen and of antibodies to that antigen. C_ε2-4 fragments were injected into skin sites 1 h before the injection of serum E.C. Skin sites were challenged 48 h later with ragweed antigen (1,000 protein nitrogen units ml^{-1} of a mixture of giant and short ragweed; Hollister-Stier). Twenty minutes later the skin sites were examined for the presence of wheal and erythema. The surface area of the reactions was estimated as follows. Transparent tape was used to transfer the outline of the reactions to paper[8] which was cut and weighed on an analytical balance. The area was read from a standard curve. Diluent consisted of 0.15 M NaCl and 0.03% human serum albumin. All injections were intradermal and 0.02 ml in volume. In each experiment a set of skin sites were also sensitized with diluent. None of these sites showed a wheal or flare reaction when challenged with ragweed antigen.

by concentrations of C_ε2-4 fragments as low as 1×10^{-8} M and concentrations of IgE (P.S.) as low as 1×10^{-9} M. Thus, a 200-fold excess of C_ε2-4 and a 20-fold excess of IgE (PS) over IgE present in serum E.C. was required to block the P-K reaction. The latter result agrees well with the results of Stanworth *et al.*[6], who found that a 10-100-folds excess of myeloma IgE (ND) over reaginic serum IgE was required to block the P-K reaction. When serum E.C. was diluted to 5×10^{-12} M IgE, it lost its ability to produce a P-K reaction. As 1×10^{-8} M C_ε2-4 completely inhibited the ability of 5×10^{-11} M IgE in E.C. serum to cause a P-K reaction, it is likely that the 200-fold excess of C_ε2-4 inhibited serum IgE to skin mast cells *in vivo by* 90%. *In vitro*, a 100-fold molar excess of C_ε2-4 fragments inhibited ^{125}I-IgE PS binding by 80% (ref. 3). Thus, the ability of C_ε2-4 fragments to inhibit IgE binding to mast cells *in vivo* and *in vitro* is comparable.

Comparison of the relative amounts of C_ε2-4 fragments and IgE (PS) needed to produce 50% reduction of the area of skin erythema induced by the P-K reaction shows that the inhibitory activity of the C_ε2-4 fragments was, on a molar basis, 30% that of natural IgE (Fig. 1). This is close to the value of 35% obtained for the relative efficacy of native IgE fragments in inhibiting ^{125}I-IgE binding to basophils *in vitro*[3].

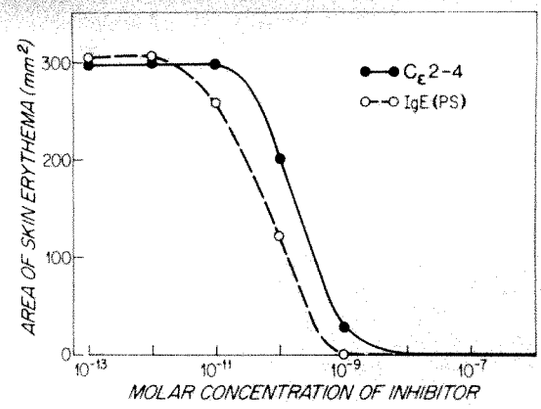

Fig. 1 Dose-response curve of inhibition of the Prausnitz-Küstner reaction. Skin sites in the forearm of a normal donor, whose serum IgE was <4 IU ml^{-1}, were injected 1 h before sensitization with decreasing concentrations of C_ε2-4 (——), IgE (PS) (- - -) or diluent (△). A 1:100 dilution of the reaginic serum E.C. containing 5×10^{-11} M IgE was used to sensitize the sites which were challenged 48 h later with ragweed antigen as described in Table 1 legend. The size of the skin erythema (flare) is shown.

Table 2 Induction of the Prausnitz-Küstner reaction by IgE-enriched fractions of reaginic serum and its inhibition by C_ε2-4 fragments

Serum (E.C.) fraction	IgE content (ng ml^{-1})	Area (mm^2) of wheal/flare at skin sites preinjected with diluent
Serum (1:100)	10	34/312
Ig enriched	7	22/210
IgE depleted	≤0.2	0/0
IgE enriched	7	27/238

An immunoglobulin-enriched fraction of serum E.C. was obtained by precipitation with 50% $(NH_4)_2SO_4$. The precipitate was reconstituted with 0.15 M saline to the initial serum volume, extensively dialysed against 0.15 M saline and diluted 1:100 in standard diluent before testing. An aliquot of the immunoglobulin-enriched fraction was circulated for 18 h at 4 °C over a Sepharose anti-IgE (PS) column[9]. The anti-IgE (PS) was raised in a goat and renderd IgE specific by absorption with human IgM, IgA, IgG myelomas and κ, λ Bence-Jones proteins coupled to Sepharose. This was followed by absorption and elution on an IgE (DAZ) column. The effluent IgE-depleted fraction was absorbed twice more over other columns of anti-IgE (PS) Sepharose. IgE was eluted from the first absorbing column with glycine-HCl buffer, *p*H 3. Eluate and effluent were dialysed extensively against phosphate-buffered saline (PBS), then diluted in standard diluent and sterilized by Millipore filtration before use. The IgE content was assayed by a solid radioimmunoassay using monoclonal mouse anti-human IgE (gift of Dr R. Siraganian) to coat the plastic polyvinyl plates and ^{125}I-anti IgE ND (Pharmacia) as a developing reagent. The assay was carried as described in ref. 9. The sensitivity of the assay was 200 pg ml^{-1}. The recipient of the P-K reaction had a serum IgE of 50 IU ml^{-1} (~120 ng ml^{-1}).

Table 3 Duration of inhibition of the Prausnitz-Küstner reaction

Inhibitor	Inhibitor concentration 10^{-7} M	10^{-6} M
C_ε2-4	12	17
IgE (PS)	14	21

Values given are days elapsed following injection of inhibitor before a successful P-K reaction could be achieved. Multiple skin sites of a normal donor with a serum IgE of 50 IU ml^{-1} were injected at day 0 with C_ε2-4 fragments, IgE (PS) or diluent. At intervals of ≥2 days (days 0, 4, 9, 12, 14, 17, 19, 21), individual skin sites were sensitized with serum E.C. (1:100 dilution), then challenged 48 h later with ragweed antigen. Sites pretreated with diluent always gave a positive wheal and flare reaction with a mean ±s.d. area of the wheal of 56±9 mm^2 and a mean ±s.d. area of the flare of 400± mm^2 for the eight successive determinations. The days shown represent the time of the first appearance of any flare and/or erythema at the challenged skin sites.

Table 3 shows that inhibition of the P-K reaction lasted for 12 days at sites that had received C_ε2-4 fragments, compared with 14 days at sites that had received IgE PS, when each was used in a 2,000-fold molar excess over IgE present in serum E.C. This inhibition lasted 17 and 21 days, respectively, at sites that had received a 20,000-fold molar excess of C_ε2-4 fragments or IgE PS.

The present experiments demonstrate that, in man, the P-K reaction can be blocked by a bacterial expression product of a human C_ε2-4 gene fragment. The inhibitory efficacy of C_ε2-4 fragments compared favourably with that of myeloma IgE (PS) both in terms of concentrations needed to inhibit the P-K reaction and in the duration of their blocking effect. As C_ε2-4 fragments are not glycosylated, glycosylation of the IgE molecule may not be essential for mast cells binding *in vivo*.

The C_ε fragment used in the present study contained the tryptophan control region of the expression plasmid pWT211 (ref. 3). Smaller C_ε fragments lacking plasmid-derived peptides are currently being constructed and tested for inhibition of the P-K reaction. Because there are no known allotypic markers for C_ε, such fragments should not be immunogenic to man. Lack of immunogenicity, potential availability in unlimited quantities and capacity to inhibit the P-K reaction for a relatively long period should make such fragments useful in attempts to prevent allergic reactions.

Increased MHC *H-2K* gene transcription in cultured mouse embryo cells after adenovirus infection

Arnon Rosenthal*†, Stephanie Wright*, Kristina Quade‡, Phillip Gallimore§, Howard Cedar† & Frank Grosveld*

The class I major histocompatibility complex (MHC) antigens are highly polymorphic[1] cell-surface proteins[2] whose expression is essential for the cellular immune response against virus-infected, abnormal and foreign cells[3,4]. Transformation of primary rat cell cultures by the oncogenic adenovirus 12 (Ad12) results in suppression of the transplantation antigens[5], thus enabling the transformed cells to escape the immune response and efficiently form tumours *in vivo*[6]. In contrast, transformation of the same cells with the non-oncogenic adenovirus 5 (Ad5) does not suppress the transplantation antigens[5] and, consequently, they elicit an effective (MHC-restricted) immune response[6]. Here, however, we show that infection of mouse embryo cells with both viruses initially increases the level of transcripts from the *H-2K*^{b} transplantation antigen gene. Both the adenovirus E1a (12S RNA) and E1b genes are required for activation of the *H-2K* gene and measurement of the relative rate of transcription indicates that the increase in the level of *H-2K* messenger RNA following infection is at least in part due to a gene-specific transcriptional activation. The newly transcribed *H-2K*^{b} mRNA is then properly transported to the cytoplasm.

Cell cultures from 16-day-old C57BL/10 mouse embryos were infected after second or third passage with wild type or mutants of Ad5. RNA was extracted 50 h after infection and the level of transcripts from the *H-2K*^{b} gene measured by S_1 nuclease protection analysis using a 600-nucleotide *Ava*II probe which spans the exon III-intron III boundary of the *H-2K*^{b} gene[7]. As indicated by the relative intensities of the 230-nucleotide S_1 nuclease-protected fragment (Fig. 1*a*), infection with Ad5 resulted in a 10–15-fold increase in the level of *H-2K*^{b} mRNA (lane 2) compared with mock-infected cells (lane 1). In contrast, infection with either the Ad5 *dl*312 E1a deletion mutant or the Ad5 *dl*313 E1b deletion mutant[8,9] did not effect an increase in the level of *H-2K* mRNA (Fig. 1*a*, lanes 3, 4). To determine whether Ad5 infection caused a nonspecific change in the rate of gene transcription and/or RNA stability, we also measured the level of histone H4 gene transcripts in the above experiments. The level of histone H4 RNA increased only 2–3-fold after Ad5 infection under conditions in which the level of *H-2K*^{b} gene transcripts increased 15-fold (Fig. 1*b*).

Measurement of the relative rate of transcription of *H-2K*^{b} in nuclei isolated from mock-infected and Ad5-infected cells indicated that the increased level of *H-2K* mRNA following Ad5 infection was at least in part due to transcriptional activation. The activation appeared to be specific for *H-2K* as the rate of transcription of the type IV collagen gene did not increase on Ad5 infection (Fig. 1*c*).

Infection of mouse embryo cultures with Ad12 also resulted in a 10–15-fold increase in the level of total cellular *H-2K*^{b} mRNA (Fig. 2*a*, lane 1) compared with mock-infected cells (lane 9). Infection with a non-tumorigenic Ad12 E1a mutant (*in* 751), which lacks functional protein products from both the 12S and 13S mRNAs because of a stop codon in the first exon, did not activate the *H-2K*^{b} gene (Fig. 2*a*, lane 8). Similarly, infection with a non-tumorigenic Ad12 mutant (*hr*1121) which does not produce the 52K (relative molecular mass 52,000) E1b protein[10] did not induce *H-2K* gene expression (Fig. 2*a*, lane 5). Infection with a weakly tumorigenic Ad12 E1a mutant

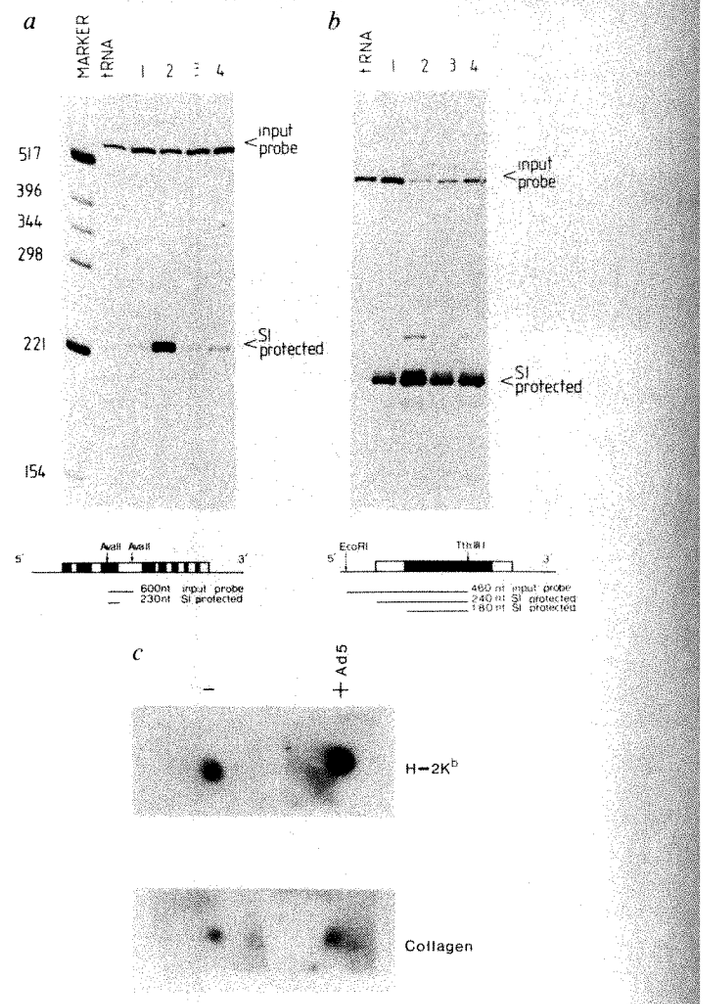

Fig. 1 *a*, *b*, S_1 nuclease analysis of *H-2K*^{b} (*a*) and histone H4 (*b*) mRNA from C57BL/10 mock-infected (lane 1), Ad5-infected (lane 2), *dl*312-infected (lane 3) and *dl*313-infected (lane 4) mouse embryo cells. Markers are ^{32}P-labelled pBr 322X Hinf. *c*, Dot hybridization of labelled nuclear transcripts from mock-infected (–) and Ad5-infected (+) C57BL/10 mouse embryo cells to *H-2K*^{b} and type IV collagen gene fragment.
Methods. *a*, A 600-nucleotide probe spanning the exon III/intron III boundary of the *H-2K*^{b} gene was end-labelled with reverse transcriptase and hybridized with 15 μg total RNA at 60 °C for 12 h in 10 μl of 80% formamide, 40 mM PIPES *p*H 6.4, 1 mM EDTA, 400 mM NaCl. The mixture was digested with 3,000 units of S_1 nuclease (Boehringer) in 300 μl of 300 mM Na-acetate *p*H 4.8, 200 mM NaCl, 2 mM $ZnSO_4$ at 20 °C for 1 h, followed by 40 °C for a further hour. S_1 nuclease-protected DNA was ethanol-precipitated, denatured and electrophoresed on a 7 M urea/7% acrylamide gel[30,31]. *b*, A 460-nucleotide probe spanning the 5′ end of the histone H4 gene was end-labelled with T4 polynucleotide kinase and hybridized with 15 μg total RNA at 52 °C as described for *a*. Samples were digested with S_1 nuclease for 2 h at 20 °C, then treated as for *a*. *c*, Nuclei were isolated from mock-infected and Ad5-infected cells. RNA synthesized in 5×10^6 isolated nuclei was labelled for 20 min with 200 μCi [α-^{32}P]UTP (3,000 Ci mmol^{-1}) in a 300 μl reaction volume as described in ref. 32. Plasmids containing the *H-2K*^{b} gene and the type IV collagen gene were linearized by digestion with *Hin*fI and *Eco*RI respectively. DNA (15 μg) was bound to a 0.45-μm nitrocellulose filter[33] and hybridized to labelled RNA from 2×10^6 isolated nuclei in a 400-μl volume[32]. After 46 h, hybridized filters were washed at 54 °C in 0.1 × S.S.C., 0.1% S.D.S. for 45 min, air-dried and exposed for 2 h.

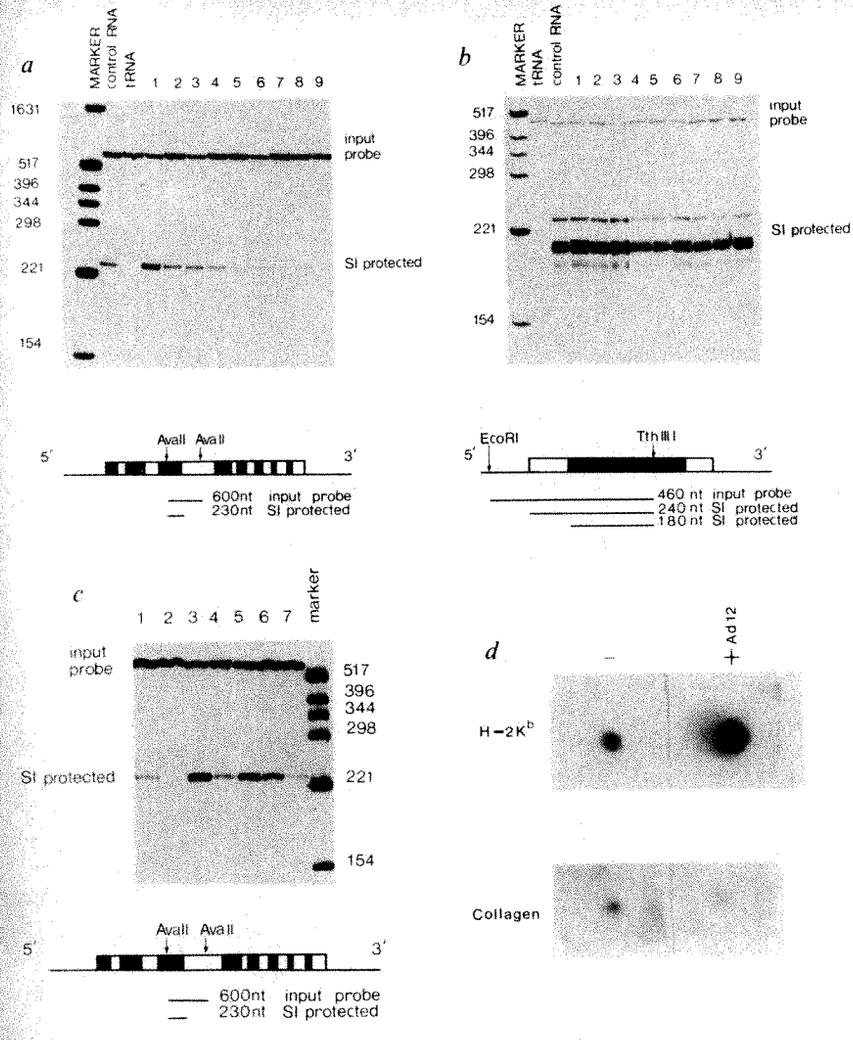

Fig. 2 *a*, *b*, S_1 nuclease analysis of $H\text{-}2K^b$ (*a*) and histone H4 (*b*) mRNA from mock-infected (lane 9) C57BL/10 cells and from cells infected with 10–20 PFU per cell of Ad12 E1a mutant *hr*751 (lane 8), Ad12 E1a mutant *hr*771 (lane 7), Ad12 E1a mutant *in*600 (lane 6), Ad12 E1b mutant *hr*1121 (lane 5), *in*751 plus *hr*1121 (lane 3), *hr*751 plus *in*600 (lane 4), *in*600 plus *hr*1121 (lane 2) and Ad12 wild type (lane 1). S_1 nuclease analysis was done as described for Fig. 1*a*, *b*. *c*, S_1 nuclease analysis of $H\text{-}2K^b$ mRNA from mock-infected C57BL/10 cells (lane 1), control tRNA (lane 2) and from cells infected with Ad12 (lane 3), *in*751 (lane 4), *hr*771 (lane 5), *in*600 (lane 6) and Ad12 *hr*1121 (lane 7) at a titre of 50 PFU per cell. S_1 nuclease analysis was done as described for Fig. 1*a*. *d*, Dot hybridization of labelled nuclear transcripts from mock-infected (–) and Ad12-infected (+) C57BL/10 mouse embryo cells to $H\text{-}2K^b$ and type IV collagen gene fragments. Methods as for Fig. 1*c*.

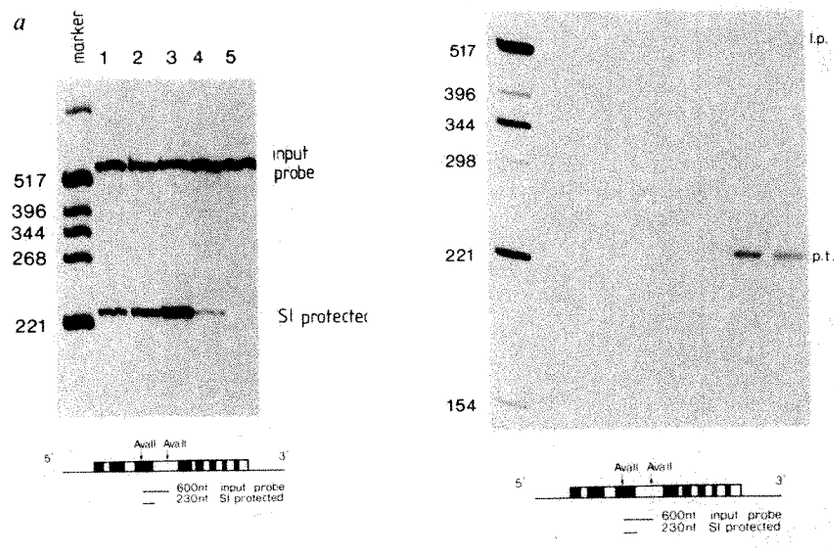

Fig. 3 *a*, S_1 nuclease analysis of $H\text{-}2K^b$ gene transcripts from mock-infected C57BL/10 mouse embryo cells (lane 4), control tRNA (lane 5) and from cells infected with polyoma virus (lane 1) or SV40 (lane 2) at a multiplicity of infection of 10–50 PFU per cell. Lane 3 contains control RNA isolated from C57BL/10 cells treated with 1,000 U ml^{-1} mouse γ-interferon. *b*, S_1 nuclease analysis of cytoplasmic(cyt) and nuclear (nuc) $H\text{-}2K^b$ mRNA from mock-infected (lane 2), Ad5-infected (lane 3, 10 PFU per cell) and Ad12-infected (lane 4, 10 PFU per cell) C57BL/10 mouse embryo cells. Lane 1 contains a tRNA control. S_1 nuclease analysis was carried out as described for Fig. 1. All lanes contain an equal amount of RNA (20 μg).

(*hr*771) which produces some E1a protein products only after a delay in permissive cells[10], or with an Ad12 E1a mutant (*in*600) which contains the normal E1a 12S RNA and a truncated 13S RNA[10] resulted in, respectively, no increase (Fig. 2*a*, lane 7) or only a marginal increase (lane 6) in the level of $H\text{-}2K$ gene transcripts at the multiplicity of infection used (10 plaque-forming units (PFU) per cell). Co-infection of E1a mutants *hr*751 and *in*600 with each other or with the *hr*1121 E1b mutant resulted in an increase in the level of $H\text{-}2K$ mRNA (Fig. 2*a*, lanes 4, 3 and 2 respectively); this effect could be caused by either complementation or an increased number of virus particles (10 PFU per cell of each; see below). The levels of histone H4 transcripts in these infections were only 1.5–2 times higher than in mock-infected cells (Fig. 2*b*).

Failure of adenovirus E1a mutants to activate the $H\text{-}2K^b$ gene may result from the lack of production of other adenovirus early proteins which are normally activated by the E1a gene products[11,12]. We therefore repeated the Ad12 mutant infections at a higher multiplicity of infection (50 PFU per cell) to allow production of other adenovirus early proteins in the absence of

the E1a proteins (ref. 13 and R. Grand and P. Gallimore, personal communication). As shown in Fig. 2*c*, infection with a high titre of E1a mutants (*in*600 and *hr*771) resulted in activation of the *H-2K*^{b} gene equal to that effected by wild-type virus. This result indicates that it is not the protein products of the E1a 13S transcript alone that activate the *H-2K*^{b} gene. The E1b 52K protein and the products of the E1a 12S RNA, or 13S exon 1 RNA, are directly or indirectly necessary for *H-2K*^{b} gene activation since high-titre infection with either the E1b 52K mutant (*hr*1121) or the E1a mutant which lacked protein products of both 12S and 13S RNAs (*hr*751) failed to significantly (less than twofold) increase the level of *H-2K*^{b} gene transcripts (Fig. 2*c*). Measurement of the relative rate of transcription of the *H-2K*^{b} gene in mock-infected and Ad12-infected cells indicated that the increase in the level of *H-2K* mRNA following viral infection was at least in part due to transcriptional activation (Fig. 2*d*).

This result may reflect the *trans*-acting enhancing properties of the E1a protein products, which can activate viral[11,12,14], newly introduced[15–18], integrated[19] and endogenous genes[20] either directly or through inactivation of cellular repressor proteins[13,21]. Alternatively, the gene activation may be mediated by a general anti-viral state induced by cellular proteins in response to either viral replication or viral proteins[21,22]; this seems unlikely, as Ad12 virus infections at 10 PFU per cell did not result in detectable levels of interferon (<4 U ml^{-1}) in the cell culture (data not shown).

The results presented here indicate that infection of mouse embryo cells with either Ad5 or Ad12 results in transcriptional activation of the MHC *H-2K* gene. Viral protein products from the 12S E1a mRNA or the first exon of the E1a gene, which is common to both 13S and 12S mRNAs, and the 52K E1B protein are necessary for this activation (Fig. 2). As yet, we do not know whether viral protein products from both the E1a and E1b regions are mediating the activation directly or via interaction with other (early) viral or cellular proteins. For example, the Ad5 E1b 58K protein binds the same p53 cellular protein as simian virus 40 (SV40) large-T antigen[24]. To determine whether other DNA tumour viruses such as SV40 mediate induction of the class I MHC genes using similar mechanisms[25] and whether induction is related to permissiveness of the virus/cell system, we infected mouse embryo cells with either SV40 (non-permissive, as is adenovirus) or polyoma virus (permissive). Infection with either of these viruses resulted in activation of the *H-2K* gene but at a lower level than that resulting from the adenovirus infections, which itself was lower than that induced by interferon in a control experiment (Fig. 3*a*).

Our results are in contrast to those of Schrier *et al.*[5] who reported a decrease in the level of cytoplasmic class I mRNA and suppression of MHC antigen expression in Ad12-, but not in Ad5-infected cells. As Schrier *et al.*[5] measured cytoplasmic mRNA, the difference could be due to a block in the transport of the newly synthesized mRNA from the nucleus to the cytoplasm. To test this possibility, the cells were infected with Ad5 and Ad12 (10 PFU per cell) and both the nuclear and cytoplasmic mRNA were quantitated. The results (Fig. 3*b*) show that the *H-2K* mRNA in the cytoplasm is increased between 10 and 15-fold in both cases, while the mRNA level in the nucleus is much lower and only visible after a longer exposure, which excludes the possibility of a block in mRNA transport.

However, preliminary experiments using radioimmune labelling of the Ad5- and Ad12-infected cells indicate that the amount of H-2K^b antigen on the cell surface increases only marginally, if at all, depsite the large increase in cytoplasmic *H-2K*^{b} mRNA (data not shown). Thus, the results suggest that infection first induces a stimulation of MHC transcription, which normally would enable a better cellular immune response against infected cells. In the case of viruses, for example Ad5 and Ad12, this may not result in an increased expression of MHC antigens on the cell surface because of other viral factors[23]. In the case of oncogenic viruses such as Ad12, this may be followed by a suppression of MHC class I gene transcripts to allow escape from immune surveillance. Whether this is caused by an immunity from natural killer cells[26–28] alone and/or from cytotoxic T cells[6] as part of an MHC-restricted response[29], is unclear.

Irreversible swelling of secretory granules during exocytosis caused by calcium

Joshua Zimmerberg* & Michael Whitaker†

The fusion of the limiting membrane of a secretory granule with the plasmalemma during exocytosis is equivalent to the fusion and release of contents that occurs when phospholipid vesicles fuse with planar bilayers[1,2]. Experiments with bilayers demonstrate that phospholipid vesicles must swell if they are to fuse[3]. Also, inhibition of exocytosis in solutions of high osmolarity occurs in several types of secretory cell[4–8]. We report here experiments on the cortical granule exocytosis of sea-urchin eggs. Exocytosis is prevented when the osmolality of the medium surrounding the eggs is raised from 1 to 2 osmol kg^{-1}. High osmolality also prevents calcium-dependent exocytosis *in vitro*. Prior treatment with calcium at high osmolality triggers fusion when normal osmolality

† To whom correspondence should be addressed.

is restored, even if calcium is removed before dilution. Addition of calcium causes the cortical granules to swell. The large increase in membrane capacitance which normally accompanies fusion[9] is absent in eggs activated in solutions of high osmolarity. Our data are consistent with the idea that a secretory granule must swell to fuse with the plasma membrane and support the hypothesis[2,10] of an osmotically driven fusion step during exocytosis.

When a sea-urchin egg is fertilized or activated with the calcium ionophore A23187, there is a rapid and complete exocytosis of the cortical granules that lie immediately beneath the plasmalemma[11,12]. This secretory event is stimulated by an increase in cytoplasmic free calcium[13]. If eggs are treated with calcium ionophore in sea water to which sucrose, sodium sulphate or stachyose is added to produce an osmotic pressure increase corresponding to 1 osmol per kg, they retain their full complement of cortical granules (Fig. 1). The inhibition is reversible in that eggs returned to sea water after treatment with ionophore in the presence of high-osmolarity solution undergo a complete exocytosis. Pretreating the eggs with osmoticant and returning them to sea water before adding calcium ionophore does not prevent exocytosis. The similar effects of 0.7 M stachyose, 0.55 M sodium sulphate and 0.85 M sucrose suggest that it is the osmotic rather than the pharmacological properties of the three substances which are responsible for the inhibition of secretion. In the presence of solutions of high osmotic pressure the granules shrink, suggesting that if swelling of the granule is hindered then exocytosis is inhibited.

We wished to determine whether solutions of high osmolality were indeed inhibiting the fusion of the secretory granule membrane with the plasma membrane or whether fusion had, in fact, taken place. Under normal conditions the granule contents take up water and salts as they disperse[14,15]. It was possible that the granule and plasma membranes had fused with the formation of an exocytotic stoma and that solutions of high osmolality were preventing granule dispersal.

One consequence of exocytosis of the cortical granules of the egg is a two- to threefold increase in the membrane capacitance which is the result of addition of cortical granule membrane to the plasmalemma[9,16]. Figure 2 shows that under conditions in which exocytosis (by which we mean both membrane fusion and the dispersal of the granule contents) is prevented, only a very small increase in membrane capacitance is observed, ~10%

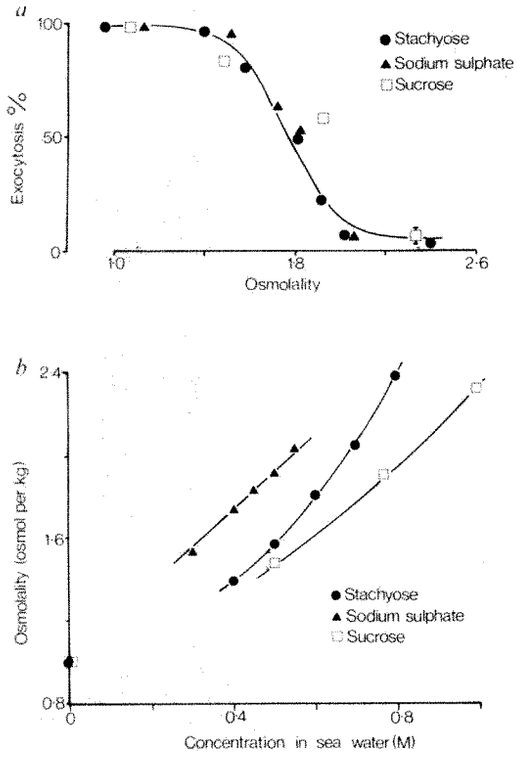

Fig. 1 *a*, Effect of increasing osmolality on cortical granule exocytosis in *Lytechinus pictus* eggs. Jelly-free eggs were resuspended in artificial sea water[19] (1.02 osmol per kg) or filtered sea water (0.90 osmol per kg) containing various concentrations of sucrose, stachyose or sodium sulphate. *b*, Osmolality was measured using a Wescor vapour pressure osmometer. Resuspended eggs were mixed with an equal volume of solution of identical composition containing 20 μM A23187 (Calbiochem), and 5 min after mixing, the extent of exocytosis of the cortical vesicles was assessed in the light microscope by gently flattening the eggs against a coverslip. The cortical granules are identified easily by their size and degree of association with the egg cortex. The granules in a disk of 50 μm radius were counted in 10 eggs selected at random. Each experiment was recorded on photographic film (Zeiss, Nikon or Leitz DIC optics with ×100, 1.25 or 1.4 NA objectives). The osmolarity of the solutions being tested was not known to the observer. Inhibition by stachyose solutions was time-dependent. After resuspension in stachyose the eggs shrank rapidly then swelled slowly towards their original size. Exocytosis eventually occurred at all stachyose concentrations tested. Stachyose did not merely reduce the rate of exocytosis, as in 0.8 M stachyose sea water, for example, no detectable exocytosis occurred for 25 min after addition of the calcium ionophore, although exocytosis was extensive at 30 min after addition. In untreated preparations, exocytosis is complete in 1 min. Temperature, 20 °C.

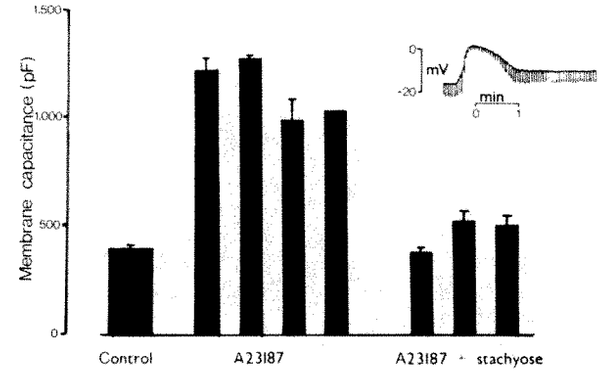

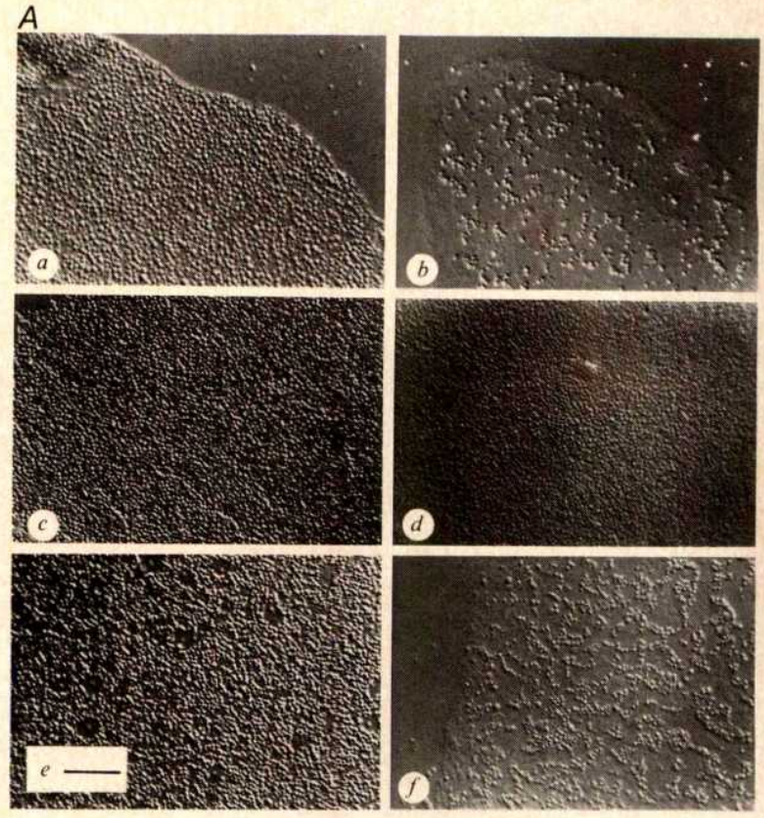

Fig. 2 Effect of stachyose on the increase in egg membrane capacitance resulting from membrane fusion. The inset shows the membrane potential alterations when the calcium ionophore A23187 (50 μM in ethanol) is added in the presence of 0.8 M stachyose in artificial sea water (2.39 osmol per kg). Membrane capacitance was measured by injecting constant current pulses through one microelectrode while recording membrane potential with a second microelectrode. Data were recorded on magnetic tape and the membrane time constant and resistance measured from five consecutive current pulse records made from tape with a chart recorder, shown (A23187 and A23187 + stachyose) as single experiments (mean ± s.e.m.). Controls are shown as mean and s.e.m. of 22 estimates of membrane capacitance in six unfertilized eggs. The rise time of the recording system was 3.5 ms. Egg input resistance before activation, 66–180 MΩ; after activation, 20–60 MΩ; current pulse, 100 or 200 pA; electrode resistance, 50–100 MΩ (KCl-filled). Temperature, 16 °C. The small increase in membrane capacitance observed when eggs are treated with A23187 in the presence of 1 M stachyose (10% of the change seen in control eggs) may result from exocytosis of 10% of the granules. The converse assumption is that it results from a decrease in the membrane resistance (R_s) between the interior of each granule and the external solution. The decrease in R_s could be distributed across the area of contact of granule and plasma membranes or could result from the appearance of a small aqueous pore or channel between the interior of each granule and the external medium. Our data indicate that the capacitance of the granule membrane (C_g) is 800 pF and that of the cell membrane (C_m) 400 pF. We have assumed that the granule membrane resistance (R_g) and granule membrane capacitance are linked by series resistance R_s to the plasma membrane resistance (R_m) and capacitance. Thus, $I = ((R_s + R_g + R_m)/R_m R_g + R_s))\ V + ((C_m R_m[R_g + R_s] + C_g R_g[R_m + R_s])/R_m(R_g + R_s))\ dV/dt + (C_g C_m R_s R_m R_g/R_m(R_g + R_s))\ d^2V/dt^2$. I, membrane current; V, membrane potential; t, time. Solving for V and t with a step change of membrane current we find from the apparent increase in membrane time constant in the presence of 1 M stachyose that if R_m is ≤200 MΩ then R_s cannot be <50 MΩ. This sets an upper limit on the size of the pores. There are ~30,000 cortical granules in a *L. pictus* egg[8], which gives a resistance per pore of 1.5×10^{12} Ω. This resistance is of the order of the resistance of the smallest ion channels so far discovered in biological membranes; we therefore believe that fusion and the formation of an exocytotic stoma have occurred in ≤10% of the cortical granules of the egg under these conditions.

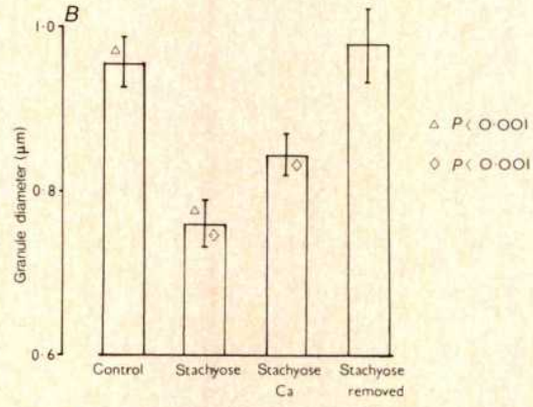

Fig. 3 ***A***, Effects of stachyose on cortical vesicle exocytosis *in vitro*. Cortical fragments consisting of vitelline coat plasma membrane and attached cortical vesicles were prepared by attaching eggs by their vitelline coat to glass coverslips with polylysine and shearing away the bulk of the egg using a jet of isolation medium (220 mM potassium glutamate, 500 mM glycine, 5 mM $MgCl_2$, 10 mM NaCl, 2.5 mM ATP, 0.5 mM dithiothreitol, 0.1 mM phenylmethylsulphonyl fluoride, 1 mM EGTA, *p*H 6.7; ref. 19). Cortical fragments on the right (*b*, *d*, *f*) have been treated with calcium (6 μM; Ca/EGTA = 0.838; ref. 19). *a*, Cortical fragment in isolation medium; *b*, fragment in isolation medium 2 min after addition of 6 μM calcium; *c*, fragment in isolation medium containing 1 M stachyose showing granules of decrease size; *d*, fragment in isolation medium containing 1 M stachyose 5 min after treatment with 6 μM calcium showing inhibition of exocytosis of cortical vesicles; *e*, fragment returned to isolation medium after treatment with 1 M stachyose-containing isolation medium (vesicles swell to their original size and will undergo exocytosis if exposed to calcium, not shown); *f*, fragment returned to isolation medium after treatment for 2 min with 1 M stachyose-containing medium containing 6 μM Ca, then for 2 min with 1 M stachyose-containing medium ($<10^{-8}$ M Ca) before returning to isolation medium ($<10^{-8}$ M Ca); exocytosis occurs in the absence of calcium when stachyose is removed. As in whole eggs, the inhibition of exocytosis is time dependent. Exocytosis occurred in the presence of stachyose after 15–20 min. At normal osmolarities, exocytosis occurs completely within 1 min of calcium addition. Temperature, 20 °C; scale bar, 10 μm. ***B***, Effects of stachyose and calcium on the size of cortical vesicles *in vitro*. Control, preparation in isolation medium; Stachyose, in 1 M stachyose-containing medium; Stachyose Ca, in 1 M stachyose-containing isolation medium containing 6 μM calcium; Stachyose removed, preparation treated with 1 M stachyose-containing medium and returned to stachyose-free medium. Photomicrographs similar to those shown in *A* were printed at ×10,000 and the diameter of 100 granules estimated from the measurements of granule perimeter made using a digitizing tablet. Mean diameter ±s.e.m. are shown. The statistical significance of the differences in mean diameter were assessed using a one-tailed Kolmogaroff–Smirnoff test. The dispersion in measured granule diameters seems to result from the dispersion of apparent granule sizes and not from errors in measurement, as the measuring procedure was precise, giving granule diameters of 0.98 ± 0.038 and 0.98 ± 0.041 μm (mean ±s.e.m.) in two separate experiments in which granules were treated with high-osmolarity stachyose and returned to normal osmolarity.

of that seen at normal osmolarity. Under these conditions, it seems that no exocytotic stoma form and that inhibition of granule swelling prevents fusion as well as dispersal. These experiments also indicate that stachyose is not preventing the ionophore-induced internal calcium transient, as we observe the calcium-associated membrane depolarization.

Inhibition of exocytosis by applying solutions of high osmolarity to the outside of the egg may be the consequence of alterations in ionic strength or viscosity in the cytoplasm caused by the shrinkage of the egg. Therefore, we investigated the effects of high osmolality on exocytosis *in vitro*.

A preparation consisting almost entirely of plasma membrane with attached cortical granules can be made by attaching eggs to glass coverslips with polylysine and shearing away the bulk of the egg[17]. This preparation gives access to the cytoplasmic face of the plasma membrane. Granules undergo exocytosis in response to micromolar calcium concentrations[18–20]. It is known that high-osmolarity sucrose solutions reduce the rate of exocytosis *in vitro* and that under these conditions the effect of calcium seems to be irreversible[21]. Inhibition by sucrose is incomplete because the cortical granules have a substantial sucrose permeability, so we used stachyose, a tetrasaccharide to which the granules are less permeable. Figure 3*A* shows the result of an experiment in which calcium was added to the preparation in the presence of stachyose (1 M in isolation buffer; 3 osmol per kg) and in which exocytosis is prevented. If calcium is removed and the preparation is allowed to remain for 5 min in EGTA-containing 1 M stachyose isolation buffer before dilution into isolation buffer containing EGTA, then exocytosis occurs on dilution to normal osmolarity. Exposing a preparation to stachyose in the absence of calcium and returning it to normal isolation medium does not result in a substantial loss of cortical granules; >90% are unaffected by this treatment. These experiments demonstrate that, even in the presence of 1 M stachyose, calcium is exerting an effect whose results persist after its removal. That is, the calcium-dependent step in exocytosis is irreversible in stachyose-treated cortices.

The planar array of cortical granules on the isolated plasma membrane forms an excellent optical image. Figure 3*B* shows that granules shrink considerably when exposed to 1 M

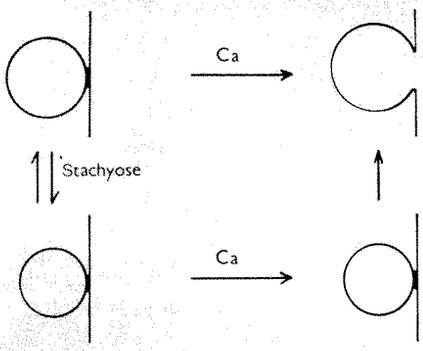

Fig. 4 Diagrammatic representation of the changes thought to be occurring in our experiments. Calcium promotes swelling and exocytosis whereas stachyose and other osmoticants cause reversible shrinkage of the cortical vesicles. If calcium is added in the presence of stachyose, the vesicle swells slightly but the swelling is insufficient to cause fusion. However, the state of the vesicle is altered irreversibly by calcium. Removal of stachyose after treatment with calcium leads to exocytosis.

stachyose in isolation medium and appear to swell slightly when they are also exposed to calcium. We suppose that calcium-induced swelling can only cause exocytosis if granules swell beyond their usual size.

Cortical granule exocytosis *in vitro* is not affected by large increases in ionic strength. We find that it occurs in solutions containing 1 M KCl, which is four times the ionic strength of cytoplasm[22]. Nor is a solution of high viscosity (30% Ficoll, relative molecular mass 400,000, 96 cP) inhibitory *in vitro*[21]. Therefore, it seems likely that high osmolality prevents exocytosis in whole eggs, as it does *in vitro*, by preventing granule swelling[21,23]. We find that higher concentrations of stachyose are needed to inhibit exocytosis *in vitro* (1 M in isolation buffer; 3.0 osmol per kg) than in whole eggs (0.7 M in sea water; 2.2 osmol per kg). We attribute this to a small but significant permeability of the granule membrane to stachyose, because a proportion (~10%) of the granules burst when returned to normal osmolarity after treatment with stachyose in the absence of calcium. This interpretation is supported by the observation that inhibition of exocytosis by stachyose is time-dependent (see Figs 1, 3 legends).

A diagram consistent with our results is shown in Fig. 4, in which calcium induces a swelling of the secretory granule which under normal circumstances leads to fusion. In the presence of solutions of high osmolarity, calcium-induced swelling is insufficient to cause fusion. But calcium has irreversible effects and fusion occurs when the granule swells further on exposure to normal osmotic pressures. We do not know why the cortical granule swells on exposure to calcium, nor why granule swelling leads to fusion. Granule swelling may result from an increased influx of ions and water across the granule membrane as a consequence of calcium-induced permeability changes or as a consequence of calcium-induced alterations of the osmotic properties of the granule contents. Fusion may occur because the granule ruptures preferentially at its point of contact with the plasma membrane, as has been suggested to explain the fusion of phospholipid vesicles with planar bilayers[24]. A mechanism in which calcium stimulates an ion exchange across the apposed granule and plasma membranes[25] seems to us less likely because exocytosis in sea-urchin eggs will occur in the absence of external monovalent ions[26].

We thank Alan Finkelstein, Fred Cohen, Ron Holz and Adrian Parsegian for comments and criticisms. This work was supported in part by funds from the NIH, the Nuffield Foundation, the Wellcome Trust, the SERC and the Royal Society.

Movement of myosin-coated beads on oriented filaments reconstituted from purified actin

James A. Spudich, Stephen J. Kron & Michael P. Sheetz*

Department of Cell Biology, Stanford University School of Medicine, Stanford, California 94305, USA

Although the biochemical properties of the actin/myosin interaction have been studied extensively using actin activation of myosin ATPase as an assay[1,2], until recently no well-defined assay has been available to measure the mechanical properties of ATP-dependent movement of myosin along actin filaments. The first direct measurements of the rate of myosin movement *in vitro*[3,4] used a naturally occurring, biochemically ill-defined array of actin filaments from the alga *Nitella*. We report here the construction of an oriented array of filaments reconstituted from purified muscle actin and the use of this array in a biochemically defined quantitative assay for the directed movement of myosin-coated polystyrene beads. We demonstrate for the first time that actin alone, linked to a substratum by a protein anchor, is sufficient to support movement of myosin at rates consistent with the speeds of muscle contraction and other forms of cell motility.

We have used severin, a protein from the amoeba *Dictyostelium*[5,6] which binds with very high affinity to the barbed end of actin filaments[7] (Fig. 1*a*). Using biotinylated severin, actin filaments can be bound to avidin immobilized on a carbon-coated electron-microscope grid, which serves as an optically clear substratum (Fig. 1*b*). In appropriate flow conditions, the bound filaments should orient with their free pointed ends in the downstream direction (Fig. 1*c*). According to H. E. Huxley's model[8], myosin moves along actin from the pointed end to the barbed end. Therefore, myosin beads placed on the actin/severin/avidin array should move upstream against the flow of buffer. The use of electron-microscope grids allows the actin array to be visualized by transmission electron microscopy after measurement of bead movement.

We followed the active movement of 40 myosin beads over distances of 10–50 μm on actin arrays demonstrated by electron microscopy to be markedly oriented (Fig. 2). The average velocity of skeletal myosin beads was 4 μm s^{-1} (26 beads, range 0.5–6 μm s^{-1}), which is close to the measured maximum rate of contraction of intact muscle under zero load (6 μm s^{-1})[9]. The average velocity of *Dictyostelium* myosin beads was 0.6 μm s^{-1} (14 beads, range 0.3–1.3 μm s^{-1}). These velocities measured with

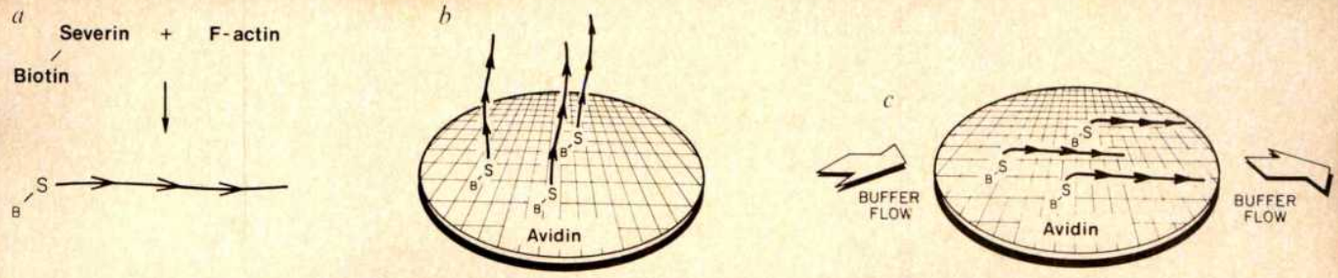

Fig. 1 Schematic representation of the method for preparing the oriented actin substratum. *a*, Severin was biotinylated as follows: 800 μl severin at 0.25 mg ml^{-1} in 50 mM sodium phosphate, *p*H 7.5, was combined with 15 μl 1 mg ml^{-1} *N*-hydroxysuccinimido biotin in dimethyl sulphoxide for 90 min at 22 °C, and the reaction quenched with 5 μl 0.1 M glycyl glycine, *p*H 7.5. The mixture was dialysed against F buffer (10 mM imidazole, *p*H 7.0, 25 mM KCl, 4 mM $MgCl_2$, 0.5 mM 2-mercaptoethanol) containing 4 mM EGTA at 4 °C for 36 h. Severin/biotin was mixed with fresh 0.25 mg ml^{-1} F-actin[13] in F buffer with 1 mM ATP and 0.2 mM $CaCl_2$ to a ratio of severin:actin 1:500 to produce a population of filaments with their barbed ends blocked by severin. *b*, *c*, A carbon-coated electron-microscope grid (200 mesh), coated with 100 μg ml^{-1} avidin in 50 mM $NaHCO_3$, *p*H 9.5, for 10 min at 22 °C, and washed with F-buffer containing 0.2 mM $CaCl_2$, was pinned onto the bottom of a channel (3 mm wide, 1 mm deep) moulded in silicone polymer. Severin/actin filaments were applied to the grid surface with laminar flow in the channel at 10 ml min^{-1} for 10 min. Unattached actin was washed from the grid surface in a flow (5 ml min^{-1}) of F buffer containing 25 μg ml^{-1} actin, 4 mM EGTA and 1 mM ATP, leaving a mat of ordered filaments.

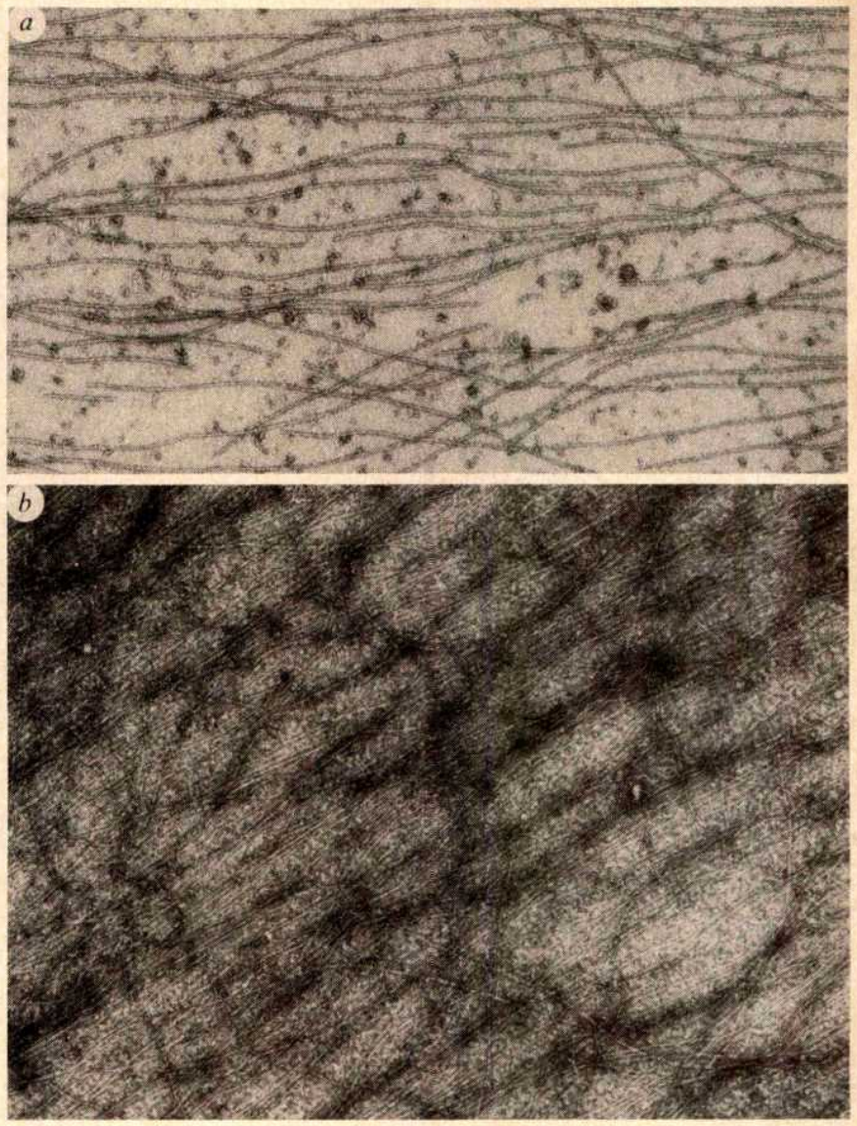

Fig. 2 Electron micrographs of F-actin oriented as described in Fig. 1 legend. *a*, Image less densely populated with actin filaments than *b*, revealing the orientation of the filaments resulting from the flow. ×58,500. *b*, Image of a dense meshwork of oriented filaments taken from a grid that supported movement of myosin beads. ×52,000. To obtain the images shown, a grid was carefully removed from the channel, noting its orientation with regard to the buffer flow. Aqueous uranyl acetate (1%) was flowed in the same direction across the grid, the excess being drawn off with filter paper from the downstream edge.

the synthetic actin array are remarkably similar to those observed using the *Nitella*-based assay[4] (2–6 μm s^{-1} for skeletal muscle myosin and 0.5–1.5 μm s^{-1} for *Dictyostelium* myosin).

These results show that, to support myosin movement, actin filaments need not be in the form of bundles (as they are in *Nitella*), nor are accessory proteins required (other than a filament anchor such as severin). In addition, our results suggest that the specific myosin type (skeletal muscle or *Dictyostelium*) is the principal determinant of bead velocity, rather than the type of actin (muscle or *Nitella*).

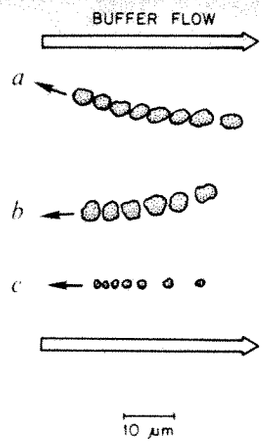

Fig. 3 Movement of myosin beads in the upstream direction with respect to the buffer flow. *a*, *b*, The two larger distinct bead aggregates were coated with 200 μg ml^{-1} *Dictyostelium* myosin and their positions shown every 10 s, corresponding to a rate of movement of ~0.5 μm s^{-1}. *c*, The smaller bead aggregate was coated with 200 μg ml^{-1} skeletal muscle myosin and its position shown every 2 s, corresponding to a rate of movement of ~2 μm s^{-1}. Myosin beads were deposited on the actin array by microinjection, suspended in F buffer containing 1 mM ATP, 0.2 M sucrose, 1 mM dithiothreitol and 4 mM EGTA. With F buffer containing 25 μg ml^{-1} actin, 4 mM EGTA and 1 mM ATP flowing in the channel at 0.04 ml min^{-1}, myosin beads and distinct bead aggregates attached to the grid surface and moved upstream. Myosin bead preparation and analysis of movement were as described previously[4]. The diagram shows typical bead movements. To be scored as an active event, bead movements had to be: (1) upstream to the direction of buffer flow; (2) at the plane of focus of the surface of the grid; (3) associated with a distinct binding event; (4) characterized by sliding rather than tumbling. In several cases, the rate of buffer flow was changed in the course of active bead movement and no effect on the rate of bead movement was observed. In contrast, movements resulting from bulk flow were: (1) downstream; (2) generally not in the plane of focus of the surface of the grid; (3) not associated with binding to the grid surface; (4) characterized by tumbling when the beads were close to the surface of the grid; (5) dependent on the presence and rate of buffer flow.

Drag on a sphere in laminar flow at low Reynolds's number is directly proportional to the bulk fluid velocity. As discussed previously[3], sufficient power is generated by a single myosin molecule to move a 1-μm bead 5 μm s^{-1} upstream against a flow of 5 μm s^{-1}. Because the flow rate near the beads in the present experiments is ≤1 μm s^{-1} (determined by measuring the velocity of unattached beads moving downstream near the substratum), it is probable that the limit on the speed of myosin movement over actin in this assay is determined by the kinetics of the biochemical reaction. The finding that some beads move slower than this maximum may reflect the presence of disorder in the array of actin filaments. Two observations are consistent with the presence of local regions of disorder. Only one-third of the myosin beads that attach to the substratum move, and those move over distances of 10–50 μm and stop, apparently tightly bound to the electron microscope grid.

Several biochemically defined actin/myosin-based *in vitro* models of cell motility have been suggested[10–12], but none of these has offered a quantitative measure of myosin movement. Many types of experiment are now possible with the biochemically defined assay described in the present study. One important application will be in the identification and purification of factors that regulate actin/myosin-mediated cell motility. This assay can also be used to study the effects of genetic manipulation of both actin and myosin structure on myosin movement along actin filaments. It should be possible to locate and define the amino-acid residues critical for the transduction of chemical energy liberated by ATP hydrolysis into the mechanical work of cellular motility.

We thank the NIH (grants GM30387 and GM33289 to J.A.S.) and the American Heart Association (M.P.S. is an American Heart Association Established Investigator) for financial support. S.J.K. is a trainee of the Medical Scientist Training Program at Stanford Medical School, supported by NIH grant GM07365.

Note added in proof: We have also observed movement on actin filaments applied by flow to severin nonspecifically bound to an electron-microscope grid surface.

Compartmentalization of sickle-cell calcium in endocytic inside-out vesicles

Much recent interest in the mechanism of dehydration of the dense subpopulation of sickle-cell anaemia (SS) red cells, including the 'irreversibly sickled cells' (ISCs), stems from the view that these relatively rigid cells have a major role in the two main clinical features of the disease, namely haemolytic anaemia and microvascular occlusion[1]. The discovery that SS red cells have an elevated calcium content and accumulate Ca^{2+} during deoxygenation-induced sickling[2–4] suggested a working hypothesis of wide appeal for the mechanism of cell dehydration: retained calcium would activate the red cell Ca^{2+}-sensitive K^+ channels[5], causing progressive net loss of KCl and water[6–8]. However, retained calcium, which seemed as weakly bound to cytoplasmic buffers as in normal red cells[9], failed to show any measurable activation of K^+ channels or Ca^{2+} pumps in metabolically normal SS cells, despite the apparent functional normality or near-normality of these transport systems[9–17]. We now offer a possible explanation for this failure. We show that, contrary to the traditional views, SS cells, and to a lesser extent normal human red cells, possess intracellular vesicles with ATP-dependent Ca^{2+}-accumulating capacity, and that nearly all the measurable calcium of fresh SS cells is contained within such vesicles, probably in the form of precipitates with inorganic or organic phosphates.

Intracellular vesicle-like structures have been described previously in electron micrographs of single sections of fixed normal red cells[18,19]. In such sections, however, true vesicles are indistinguishable from artefacts resulting from occasional membrane infoldings. To demonstrate that the vesicles are fully contained within the cell, it is necessary to examine the three-dimensional structure of a representative number of cells in serial section. Figure 1 shows typical runs of consecutive sections of fresh SS cells and ghosts chosen to illustrate genuine and artefactual vesicular images. Analyses of 75 SS cells, 59 SS ghosts and similar studies (not shown) with 36 normal red cells and 62 normal ghosts, revealed that both SS and normal red cells possess fully enclosed vesicles. In at least 84% of the normal cells, one to four tiny vesicles were found, which were ~0.1 μm in diameter. The vesicles were usually contained within one or two consecutive 0.10–0.15-μm sections, but occasionally extended over up to seven such consecutive sections, with tubular or

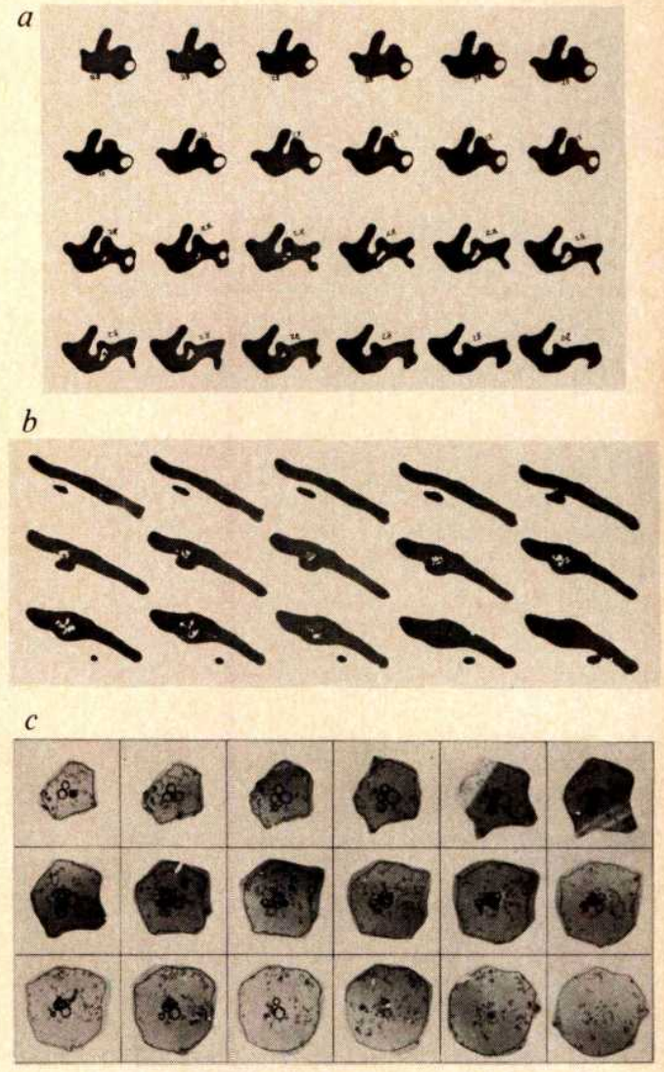

Fig. 1 Genuine and artefactual vesicular images. The cell in *a*, which is not an ISC, illustrates the appearance of a genuine, fully-enclosed vesicle (near the centre) containing some electron-dense material, as well as a long tubular artefact with open communication to the medium (on the right). The cell in *b* is part of an ISC and illustrates the complex structure of a large vesicle also containing electron-dense material. The images in *c* are from an SS ghost. The mottled background is characteristic of SS cells alone and may be caused by haemoglobin (Hb) aggregates. (Following hypotonic lysis, SS ghosts viewed under phase microscopy contained many dense aggregates which moved about within the ghosts; these were rare and much smaller in normal ghosts, and probably represent clumps of denatured Hb.) Many of the vesicles seen in the SS ghosts also contain, or are associated with, electron-dense material. The relative vesicular volume in individual ghosts was estimated by weighing cut-outs of photocopies of the serial sections of SS ghosts and the vesicles contained within them; it varied from <0.02% to 19%, with typical values of ~0.1–0.4%. The high electron density of the cytoplasm and vesicle-associated precipitates, as well as the convoluted shape of most vacuolar spaces, precludes such estimates in the serial sections of intact SS cells.

Methods. Blood was drawn from normal subjects and from sickle-cell anaemia patients, into heparinized containers. Only SS cells are shown in this figure. The red cells were washed four times in saline and packed at 1,200*g* for 1 min in small microfuge tubes. 20 μl of packed cells was fixed by addition to 1 ml of buffer containing 2.5% glutaraldehyde and (in mM): KCl, 75; NaCl, 75; HEPES-K (*p*H 7.2), 10. After 30 min at room temperature, the cells were washed twice with buffer alone. The cell pellets were post-fixed in 1% osmium tetroxide, dehydrated in graded ethanol solutions and embedded in Araldite resin. Serial sections (0.10–0.15 μm) were cut, mounted on Pioloform support films and slotted grids and stained with lead citrate[26]. Similar images were obtained with red cells fixed in 0.15 M cocodylate buffers, or by using 1% osmium tetroxide with or instead of glutaraldehyde. With all solutions, similar low proportions of deformed cells, such as those illustrated in *a*, were seen with preparations of SS cells but not with normal cells. Phase-contrast inspection of specimens before and after fixation did not reveal major differences other than in the overall rigidity of fixed cells. Ghosts were prepared by lysing packed cells in 50 vol. of ice-cold medium as described in Fig. 4 legend. Intact red cells were packed and 20 μl transferred to microfuge tubes containing 1 ml of lysing medium with 1% osmium tetroxide. After 1 h at room temperature, the ghosts were washed once with lysing medium alone, and the pellets processed as for the intact cells.

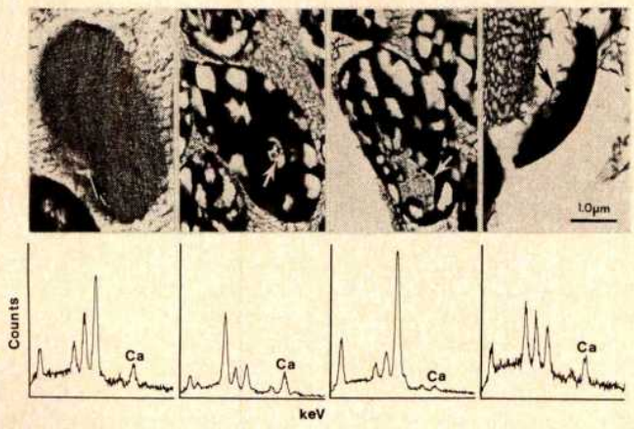

Fig. 2 Top, frozen dried cryosections of the dense ISC-rich fraction of SS cells (see Fig. 4 legend), showing four typical examples of Ca^{2+}-containing vacuoles. The vacuoles are indicated by arrows, and the spectra obtained when the electron beam was focused on the content of the vacuoles are shown beneath each micrograph. The holes in the two red blood cells in the centre are a result of ice crystal damage typically observed in the deeper part of the specimens. Analysis of the walls of the holes gave phosphorus concentrations similar to those of the adjacent cytoplasm, whereas the walls of the calcium-containing vacuoles were high in phosphorus, consistent with their being membrane-enclosed. Occasional cells, such as that illustrated in the extreme left-hand panel, were much less electron-opaque than the majority and, while some also showed vacuoles with high Ca content, the ionic composition of their cytoplasm (not shown) suggested that they were partially haemolysed.

Methods. Small droplets (<1 mm diameter) of the red cells were placed on the end of a bamboo splinter and plunged into supercooled Freon 22. The droplets were sectioned at −130 °C in a cryoultramicrotome and the ~100-nm-thick sections were placed on carbon support films and freeze-dried at $<10^{-5}$ torr. The freeze-dried cryosections were carbon-coated and analysed at −100 °C on the cold stage of a Philips 400T transmission electron microscope operated at 80 kV and equipped with a 30-mm^2 Kevex energy dispersive detector connected to a Kevex multichannel analyser and a PDP11/34 computer. The duration of individual analyses was 150–300 s, with a probe current of ~1 nA. The equipment configuration and its operating characteristics have been described elsewhere[20,21].

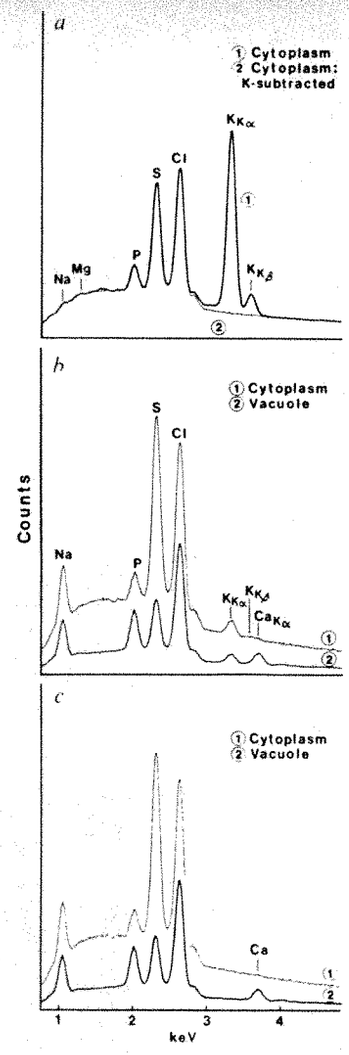

Fig. 3 Averaged X-ray spectra from normal (*a*) and sickle (*b*, *c*) red blood cells. *a*, Spectrum of normal red cells before (1) and after (2) subtraction of the potassium Kα and Kβ peaks, showing that the spectrum is flat in the calcium region. *b*, Averaged spectra (15 analyses obtained with focused 100-nm-diameter probes) for the cytoplasm (1) and (15 analyses) with probes focused over the vacuoles (2). CaKα indicates the position of the calcium Kα peak. *c*, The same spectrum as *b*, with the potassium Kα and Kρ peaks subtracted[27] to contrast the high calcium concentration within the vacuoles with the very low concentrations in the cytoplasm.

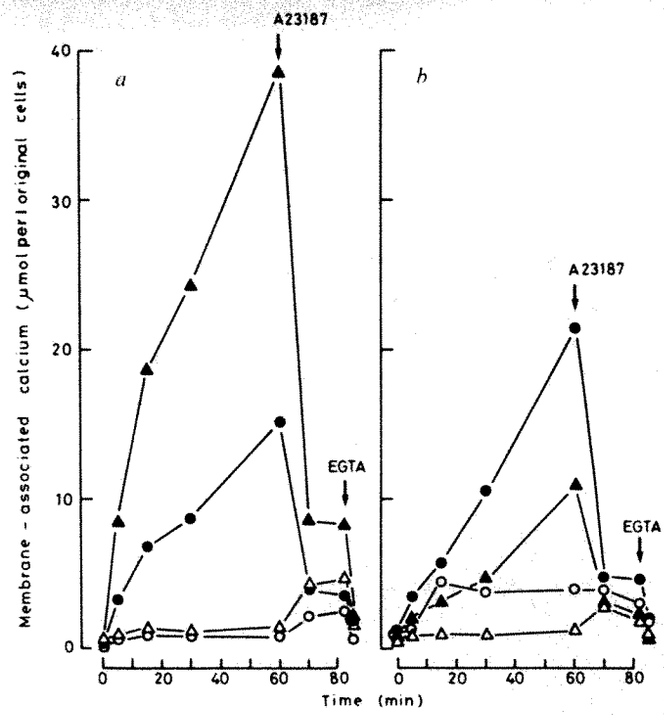

Fig. 4 Calcium uptake by sickle (*a*) and normal (*b*) disrupted red cell membranes in the presence and absence of ATP. Open symbols, ATP-free conditions; solid symbols, ATP added and maintained. ○, ●: Second-lightest cell fraction; △, ▲: densest cell fraction.

Methods. Red cells from normal and sickle-cell anaemic blood were separated on Stractan (arabinogalactan) density gradients[28] to obtain the second-lightest fractions (diskocytes free of white cells, platelets and most reticulocytes) and the densest fractions (~70% irreversibly sickled forms (ISCs) from the SS cells). After separation, the cells were washed twice in ice-cold medium A containing (in mM): NaCl, 75; KCl, 75; EGTA 0.1; Tris-Cl *p*H 7.5, 10, and lysed in 50 vol. ice-cold medium containing 2.5 mM K-HEPES *p*H 7.6 and 1 mM $MgCl_2$. These conditions are known to completely prevent spontaneous inside-out vesicle formation[22]. The membranes were centrifuged at 17,000 r.p.m. for 15 min in the cold, and the pellets were frozen and thawed once to ensure complete cell lysis. Each pellet was suspended in 1 ml ice-cold buffer containing 10 mM KCl, 50 mM Na-HEPES *p*H 7.5, 1 mM $MgCl_2$, 40 μM $^{45}CaCl_2$ and 3 μM calmodulin, and divided in half to receive either 1 mM Na-ATP with 5 mM creatine phosphate and 50 U ml^{-1} creatine phosphokinase (to maintain ATP), or 50 U ml^{-1} hexokinase and 25 mM glucose (to secure complete ATP depletion). After zero-time samples had been taken in the cold, the suspensions were incubated at 37 °C with stirring. Samples (50 μl) were delivered onto Millipore filters (type HA, 0.45 μM, prewashed with the suspension buffer containing, in addition, 2 mM $^{40}CaCl_2$) on a vacuum manifold, washed twice with the same ^{40}Ca-containing buffer, and the filters dissolved in scintillation fluid in counting vials. At the times indicated, ionophore A23187, at a moderately high concentration equivalent to 50 μmol per l of original cells, and subsequently 2 mM Tris-EGTA, were added to the incubation mixtures.

convoluted shapes. Enclosed vesicles were present in all the SS cells and ghosts. Relative to normal cells, SS vesicles were more numerous and much larger (particularly in the ISCs), showed marked variations in shape, size and numbers per cell, were often multi-lobed and contained electron-dense inclusions.

The compartmentalization of calcium in sickle cells was established directly by electron-probe X-ray microanalysis[20,21] of cryosections made from the dense, ISC-rich cell fraction. Figure 2 illustrates the X-ray spectra and Ca^{2+} peaks corresponding to representative vesicular images seen in frozen dried sections of ISCs. Figure 3 shows averaged X-ray spectra of normal red blood cells, and the vacuoles and adjacent cytoplasm of ISCs. Highly significant Ca^{2+} peaks were recorded only from the vacuoles that also contained higher concentrations of phosphorus than the adjacent cytoplasm. The P/Ca ratio within the vacuoles varied from 1.5 (the ratio in hydroxyapatite) to 7.6, suggesting that organic phosphates may participate in the formation of precipitates. The calcium content of the vacuoles averaged 35 mmol per kg dry wt. With about 0.3–0.4 kg dry wt per l of cells, and the range of vesicular volumes found in ghosts (see Fig. 1 legend), the measured intravesicular calcium concentration can easily account for mean total cell Ca^{2+} values in the range observed[10,12], that is, 40–100 μmol per l of cells.

If endocytic inside-out vesicles are to account for the observed calcium accumulation by SS cells during sickling, they must have ATP-dependent Ca^{2+} pumps capable of pumping Ca^{2+} inward, in competition with the Ca^{2+}-extrusion pumps of the outer cell membrane. The ATP-dependent, Ca^{2+}-accumulating capacity of any vesicles that might have resisted the procedures applied to disrupt the outer cell membrane, was investigated by the protocol described in Fig. 4 legend. The results of four similar experiments (see Fig. 4) demonstrate that disrupted

membranes from both SS and normal red cells are capable of substantial ATP-dependent Ca^{2+} accumulation in the presence of non-limiting concentrations of Ca^{2+}-pump substrates and cofactors. That accumulation of Ca^{2+} was uphill was demonstrated by the collapse of the Ca^{2+} gradient on addition of the calcium ionophore A23187 before the addition of excess Ca^{2+} chelator. In all instances, ATP-dependent Ca^{2+} uptake was maximal at the start of the incubation, without noticeable delay; this argues against uptake by newly formed inside-out vesicles as, even under the most favourable conditions for spontaneous endocytosis, more than 6–15 min of incubation at 37 °C are required to produce sealed inside-out vesicles[22]. Therefore, the observed uptake must represent the Ca^{2+}-accumulating capacity of those endocytic inside-out vesicles that either resisted lysis (possibly the same as Palek's ghost-associated ^{45}Ca fraction[4]), or which re-sealed spontaneously after lysis.

The results presented here explain the paradox of the silent calcium in SS cells and circumscribe the possible role of calcium in the generation of ISCs. Cytoplasmic Ca^{2+} concentrations must be increased transiently, at least, to lead to accumulation within endocytic inside-out vesicles. The possibility remains[1] that in some cells such Ca^{2+} transients could briefly activate K^+ channels and initiate the process of dehydration (thereby further promoting the sickling process), eventually resulting in ISC formation. Recent work lends some support to this possibility[23].

The endocytic inside-out vesicles present in red cells could record cumulatively any episodes of increased Ca^{2+} permeability as an increase in the calcium content of the cells. In view of the evidence for endocytic inside-out vesicles capable of Ca^{2+} accumulation in normal red cells (Fig. 4), the absence of a measurable pool of ionophore-mobilizable Ca^{2+} in these cells[10] argues against their having periods of substantially increased Ca^{2+} permeability, such as those proposed to occur with normal red cells during microcirculatory shear stress[24]. A normal spleen, however, might 'pinch-off' Ca^{2+}-loaded vesicles from traversing red cells[19], thus erasing such a record, whereas the functional asplenia of sickle cell anaemia patients[25] could account for the persistence of such vesicles.

We thank Mr J. Silcox for cryoultramicrotomy and the Department of Anatomy, University of Cambridge, for facilities to perform the serial section studies. The work was supported by NIH grants HL28018 and HL 21016 (to R.M.B.), HL 15835 to the Pennsylvania Muscle Institute (to A.V.S. and A.P.S.) and by grants from the MRC (UK) and Wellcome Trust (UK) (to V.L.L.).

Reorganization of α-fodrin induced by stimulation in secretory cells

Dominique Perrin & Dominique Aunis*

Unité INSERM U-44, Centre de Neurochimie du CNRS, 5 rue Blaise Pascal, 67084 Strasbourg Cedex, France

Spectrin is an ubiquitous protein composed of heterodimers with α and β subunits. It was first described in erythrocyte cell membranes (see ref. 1 for review) and subsequently in brain, intestinal brush borders, kidney, liver and adrenals[2–8]. Brain spectrin (fodrin) α-subunit, responsible for actin binding, has a relative molecular mass (M_r) of 240,000, whereas the β-subunit, involved in membrane attachment, has an M_r of 235,000 (refs 1, 3, 9–13). The membrane of secretory granules from adrenal chromaffin cells increases the viscosity of F-actin solution[6,14], and spectrin-like protein is associated with storage granule and plasma membranes[6]. Here, we report the localization of fodrin in secretory cells using monospecific antibodies against the α-subunit of fodrin using indirect immunofluorescence. We find that the α-subunit forms an intensely stained continuous ring in the subplasmalemmal region of resting chromaffin cells. On stimulation of the cell with nicotine, high potassium or ionophores in the presence of calcium, fodrin forms patches. This aggregation is inhibited by trifluoperazine, hence the entrance of calcium into cells following cell depolarization seems to be the calmodulin-dependent stimulus initiating patch formation.

The chromaffin cell of the adrenal medulla is often used as a model to study the secretory process in neuroendocrine cells[15,16]. The recent development of primary cultures of adult chromaffin cells isolated from bovine adrenal glands[17–20] provides a system that can be used to probe the cellular mechanism underlying secretion.

To examine fodrin localization in cultured chromaffin cells we raised antibodies against the α- and β-subunits of bovine brain fodrin. Using immunoaffinity-purified antibody to bovine brain membrane β-fodrin no staining of chromaffin cells was observed, indicating that brain β-fodrin is immunologically distinct from that of paraneuronal cells (Fig. 1*a*). We confirmed these observations by immunoblotting experiments on chromaffin cell cytoskeletal proteins (data not shown). In contrast, immunoaffinity-purified antibody to the α-subunit of bovine brain stained the chromaffin cell periphery as an intense fluorescent ring (Fig. 1*b*). The α-fodrin antigens were apparently not accessible to the cell surface because no antibody staining occurred unless the cells were first permeabilized with Triton X-100. Preimmune serum or antiserum absorbed with fodrin did not decorate chromaffin cells. Thus, we conclude that α-fodrin antigens are concentrated in the subplasmalemmal region of cultured chromaffin cells.

In 85 ± 5% of cells from four different primary cultures, α-fodrin was visualized as a continuous ring. In the remaining 15% a different staining pattern was observed; α-fodrin antigens still occurred in the subplasmalemmal region but were aggregated in some places, producing a discontinuous labelling, suggesting that α-fodrin organization is related to secretory activity. Therefore, we stimulated cultured chromaffin cells with nicotine and then stained for α-fodrin antigens. In these experiments, antibody against dopamine β-hydroxylase (DBH), a marker for the inner surface of granule membranes, was also added during the stimulation period. This marker is known to be inserted into the plasma membrane during exocytosis[21] (Fig. 1*g*, *h*). Cells were examined, counted and classified as either showing a continuous subplasmalemmal fodrin ring or discontinuous labelling with patches. We found a close relationship between the number of cells displaying patchy fodrin distribution and

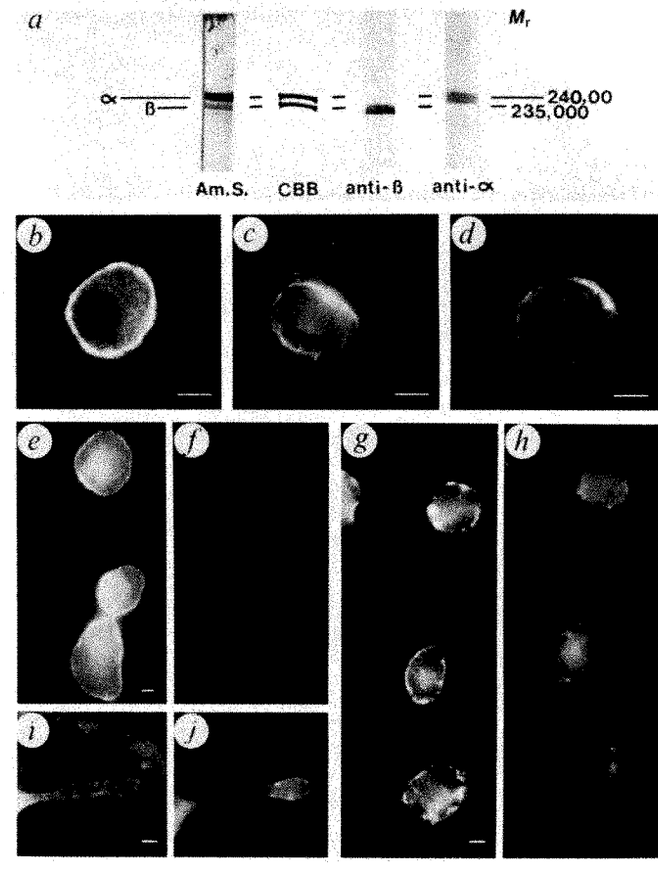

Fig. 1 Immunofluorescence localization of α-fodrin in cultured chromaffin cells. ***a***, Characterization of anti-α-fodrin and anti-β-fodrin antibodies. Bovine brain fodrin α- and β-subunits were separated by polyacrylamide slab gel electrophoresis and stained with Coomassie brilliant blue (lane CBB). After transfer to a nitrocellulose sheet, one lane was stained with Amido black (lane Am.S.), and the other two reacted with either anti-α-fodrin (anti-α) or anti-β-fodrin (anti-β) monospecific immunoaffinity-purified antibody. Bound immunoglobulins were then detected with goat peroxidase-conjugated anti-rabbit immunoglobulins (Nordic Immunologicals) and chloro-2-naphthol[30,31]. No cross-reaction of anti-α-fodrin with the β-subunit or anti-β-fodrin with the α-subunit was observed. ***b–d***, Localization of α-fodrin antigens in resting and stimulated chromaffin cells. Chromaffin cells in culture were incubated for 10 min at 22 °C with no secretagogue (*b*) or with 56 mM K^+ (*c*) or 25 μM X537A (*d*) in the presence of 2.2 mM Ca^{2+}. Cells were then processed for α-fodrin localization using immunofluorescence microscopy. ***e–j***, simultaneous localization of α-fodrin antigens (*e, g, i*) and exocytotic sites (*f, h, j*) in chromaffin cells in culture stimulated in the absence (pair *e, f*) or presence (pairs *g, h*; *i, j*) of external calcium. Antiserum to DBH was used as a marker for the inner surface of granule membrane as it is transiently becoming accessible during exocytosis. Chromaffin cells in culture were washed and incubated for 10 min at 22 °C in 2.2 mM Ca^{2+}-Locke's solution containing specific (ref. 6) rat anti DBH antiserum (dilution 1:100) with 10 μM nicotine (pair *g, h*) or 25 μM X537A (pair *i, j*); *e, f*, incubation performed in Ca^{2+}-free (5 mM EGTA) Locke's solution in the presence of 10 μM nicotine. Cells were then processed for immunofluorescence microscopy. Scale bars, 10 μm.

Methods. Anti-fodrin antibodies: Antibodies against fodrin purified from bovine brain membranes[32] were raised in rabbits. Brain fodrin was eluted from SDS electrophoresis[33] and injected into rabbits with Freund's complete adjuvant and 3 weeks later with Freund's incomplete adjuvant. To purify monospecific anti-α- and anti-β-fodrin antibodies, purified bovine brain fodrin was separated on 4–8% SDS/polyacrylamide slab gels and transferred to nitrocellulose sheet (30 V; 320 mA; 15 h; see ref. 34). After staining the proteins with Ponceau red, the strip corresponding to each fodrin subunit was cut out and incubated for 60 min at 37 °C in a solution of 3% bovine serum albumin in phosphate-buffered saline (PBS). Nitrocellulose strips were then incubated for 120 min at 20 °C in anti-fodrin antisera diluted 10-fold with PBS. After extensive washings with PBS, bound immunoglobulins were eluted with 0.2 M glycine-HCl (*p*H 2.8) for 4–5 min[35], and the eluate immediately neutralized with 1 M NaOH. The solution was then dialysed overnight against 0.2 M borate buffer (*p*H 7.8), analysed at 280 nm, divided into aliquots and stored at −70 °C. Chromaffin cells in culture: Chromaffin cells were isolated from fresh bovine adrenal glands by retrograde perfusion with collagenase and purification on self-generating Percoll gradients[17,31]. Cells were suspended at a concentration of 10^5 cells ml^{-1} of Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum containing cytosine arabinoside (3 μg ml^{-1}), streptomycin (50 μg ml^{-1}) and penicillin (50 U ml^{-1}). Cells were seeded on rat-tail collagen-coated glass coverslips, which were placed into Falcon Petri dishes (35 mm diameter). Cells were cultured at 37 °C in an H_2O-saturated atmosphere of 95% air/5% CO_2 and used within 7 days after plating. Immunofluorescence microscopy: After stimulation (as indicated) cells were rapidly (1 min) rinsed in PBS, *p*H 7.4, and then fixed with 4% formaldehyde in PBS and permeabilized with acetone[31]. After a further wash, cells were treated with normal swine and goat immunoglobulins (2 mg ml^{-1}), then incubated with monospecific anti-α-fodrin immunoglobulins (1–2 μg on each coverslip) overnight at 4 °C. Finally, antibodies were detected with swine fluorescein-conjugated anti-rabbit immunoglobulins (Nordic Immunologicals; diluted 1:50 in PBS) and, when necessary, with goat rhodamine-conjugated anti-rat immunoglobulins (Nordic Immunologicals; diluted 1:60 in PBS). Coverslips were mounted in 1:1 mixture of 87.5% glycerol and PBS containing 50 mM Tris, 20 mM dithiothreitol at *p*H 8.1. Preparations were examined with a Zeiss Universal microscope using epi-illumination and a Zeiss Planapo 63×/1.4 oil immersion objective, with 450–490-nm and 515–560-nm filters for fluorescein and rhodamine fluorescence, respectively.

the external nicotine concentration (Fig. 2). At 10 μM nicotine, ~70 ± 10% of chromaffin cells showed a redistribution of fodrin antigens. There is a linear relationship between α-fodrin reorganization and catecholamines released at a given nicotine concentration (correlation coefficient 0.93, data not shown). Patches of α-fodrin antigens formed in 80% of cells 10 min and 94% of cells 25 min after nicotine stimulation, demonstrating the time-dependency of fodrin reassembly (Fig. 3).

To examine further the aggregation phenomenon of α-fodrin antigens, we show that 56 mM K^+ also induces reorganization of α-fodrin in the subplasmalemmal space similar to that provoked by nicotine (Fig. 1*c*). In addition, the formation of patches induced by high potassium and nicotine proceeded with the same time-course (Fig. 3), but fewer cells (55–60%) had K^+-induced patches. Note that even at relatively high depolarizing K^+ concentrations, catecholamine secretion is significantly less than with nicotine or acetylcholine[22]. Chromaffin cells stimulated with nicotine were also examined 60 min after stimulation, when α-fodrin labelling had returned to the level in resting cells even though anti-DBH staining of cell membranes was still visible (data not shown).

Thus, nicotine and high potassium produce similar effects on fodrin organization in secretory cells. Because the chromaffin cell requires external calcium in addition to a stimulus to secrete catecholamines and peptides, we next examined the effect of external calcium on fodrin movements on cells stimulated either with nicotine or high potassium. In the absence of external calcium ($<10^{-8}$ M), catecholamine secretion was blocked and the alteration of α-fodrin organization was no longer observed (Figs 1*e, f*; 2). The Ca^{2+}-dependence of fodrin reorganization was also examined by incubating cells in the presence of X537A, an ionophore provoking catecholamine release in the presence of calcium. In these experiments, incubation of cells with 25 μM X537A in the absence of calcium did not result in modification of fodrin localization, whereas in the presence of calcium there was a drastic rearrangement of fodrin (Fig. 1*d, i*). Treatment of cells with the more specific Ca^{2+} ionophore A23187 gave identical results (data not shown). These data indicate that the main stimulus activating α-fodrin movements results from the rise of intracellular calcium concentration following cell depolarization[23].

The α-subunit of brain fodrin is known to bind calmodulin[24]. Although α-fodrin from the adrenal medulla has not yet been shown to be calmodulin dependent, we tested the effect of trifluoperazine, a calmodulin antagonist, on α-fodrin organization in secretory cells. Nicotine-induced rearrangement of fodrin was abolished totally in 5×10^{-6} M TFP (Table 1). This concentration also inhibited 90% of the catecholamine release (ref. 25 and V. Ceña and D.A., unpublished results).

Because there is an exocytotic stage of secretion in chromaffin cells, it is possible that fodrin redistribution is the passive consequence of secretory vesicle fusion with the plasma membrane. Stimulation is followed by the addition of much of the vesicle membrane to the plasma membrane; therefore, some

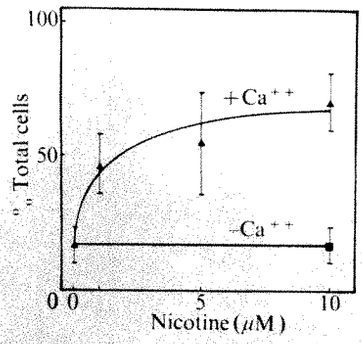

Fig. 2 Effect of nicotine concentration on the number of chromaffin cells showing discontinuous α-fodrin staining. Chromaffin cells in culture were washed with 2.2 mM Ca^{2+} or Ca^{2+}-free (5 mM EGTA) Locke's solution and stimulated for 10 min at 22 °C with nicotine as indicated. Cells were then rapidly washed, fixed and processed for α-fodrin localization as described in Fig. 1 legend. For each nicotine concentration, 150 cells were examined and classified. Experiments were repeated three times on three different cultures of chromaffin cells. Each value is the mean ± s.d.

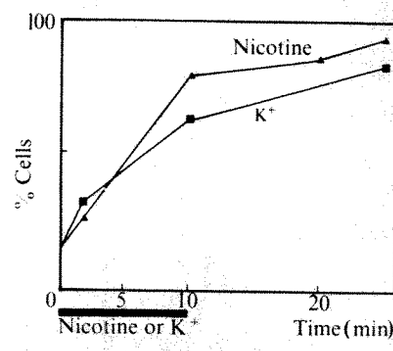

Fig. 3 Kinetics of α-fodrin patch formation in chromaffin cells. At indicated times after stimulation either with 10 μM nicotine or 56 mM K^+ at 22 °C in the presence of 2.2 mM Ca^{2+}, cells were fixed, stained for α-fodrin (see Fig. 1 legend) and counted. Stimulation with secretagogue was for a maximum of 10 min and then cells were washed with Locke's solution. Each value is the mean of two experiments.

clearing of plasma membrane proteins would be expected. In separate experiments (O. K. Langley, D.P. and D.A., unpublished results), resting and nicotine-stimulated chromaffin cells were labelled with anti-D2 antibody, D2 being a glycoprotein belonging to the family of cell-adhesion molecules and found on the surface of all chromaffin cells[26]. No alteration of D2 localization was found. In addition, examination of the paired cells in Fig. 1*g*, *h*, did not show any obvious correlation between fodrin patches and exocytotic sites; the latter has been visualized with the anti-DBH antiserum. Therefore, the possibility that fodrin movements result only from vesicle membrane integration into cell membrane is highly unlikely.

The redistribution of α-fodrin in the subplasmalemmal region of cultured secretory cells after stimulation of the cell-surface receptor suggests that the subplasmalemmal cytoskeletal organization is affected by interactions between surface receptors, internal calcium concentration, calmodulin and environmental stimuli. The organization of actin in stimulated cultured cells was also examined, but changes in the actin distribution were much more difficult to evaluate because its distribution[18] in resting cells is variable (that is, it is either localized as fibres or dots, diffuse in the cytoplasm or underlying the cell membrane).

The present study is the first demonstration that fodrin is redistributed when secretory cells are stimulated externally. Fodrin-related proteins have been localized previously in the cortical cytoplasm of many cells and found to redistribute during ligand-induced aggregation of receptors in fibroblasts and during capping on B and T lymphocytes[27,28]. 'Patching' has been described as a segregation of plasma membrane-associated macromolecules to certain domains of the membrane. Hence, fodrin seems to mediate surface receptor interactions with the cytoskeleton, and may act as a specific linker of certain membrane-associated proteins to the filamentous cytoskeleton.

Table 1 Effect of trifluoperazine (TFP) on α-fodrin distribution in resting and stimulated chromaffin cells in culture

Experimental conditions (in 2.2 mM Ca^{2+}-containing Locke's solution)	No. of cells showing α-fodrin rearrangement (%)
Control	5-10
Nicotine 10 μM, 10 min	80-90
TFP 5.10^{-7} M, 20 min + nicotine 10 μM, 10 min	60-65
TFP 5.10^{-6} M, 20 min + nicotine 10 μM, 10 min	5-10
TFP 5.10^{-6} M, 20 min	5-10

In addition, fodrin movements may also be involved with granule movement. The subcortical cytoplasm of eukaryotic cells where fodrin seems to be concentrated is characterized by a dense fibrillar array of interacting filaments and associated proteins. In resting cells the fodrin fluorescence ring probably reflects this subplasmalemmal dense network, which, when gelled, could act as a physical barrier preventing granules from moving towards the cell membrane and undergoing exocytosis. In stimulated cells, fodrin movements may cause the appearance of free spaces in the continuous ring resulting from a calcium-dependent solation and thereby allow granules to move. This solation process seems to be calmodulin dependent because trifluoperazine blocks both secretion[25] and fodrin movements. It is of interest to note that trifluoperazine-treated cells have been shown to contain an increased number of granules within 200 nm of the plasma membrane[29].

We thank Drs M. Ladona, M. F. Bader, A. Garcia, N. Grant, O. K. Langley and J. J. Nordmann for fruitful discussions, Ms D. Thiersé for technical assistance, Ms F. Herth for preparing the manuscript and Drs R. Cassoly and L. A. Pradel for the gift of anti-human erythrocyte spectrin used in earlier stages. This work was supported by MRI grant 82 E 1195.

Microorganisms are generally used for mass production of foreign gene products, but multicellular organisms such as plants have been proposed as an economical alternative. The silkworm may be useful in this context as it can be cultured easily and at low cost. We have therefore developed a virus vector to introduce foreign genes, for example, the gene for human α-interferon (IFN-α), into silkworms. We used the baculovirus *Bombyx mori* nuclear polyhedrosis virus (BmNPV) which has a large (>100 kilobases, kb) double-stranded circular DNA genome within its rod-shaped capsid. Baculoviruses have been used previously as vectors for expression of β-interferon and β-galactosidase in established cell lines[1,2]. Although BmNPV has not been used previously as an expression vector, it has an advantage over the baculovirus *Autographa californica* NPV in that it has a narrower host range and will not grow in wild insect pests in the field. In the present study, the polyhedrin gene encoding the major inclusion body protein of BmNPV was identified by hybridization with complementary DNA and cloned in a plasmid. For insertion of foreign genes, we constructed a recombinant plasmid carrying a polylinker linked to the promoter of the polyhedrin gene, and inserted the IFN-α gene into this plasmid. The resulting plasmid and the BmNPV genomic DNA were co-transfected into BM-N cells, and stable recombinant viruses isolated by plaque assay on BM-N cells. The recombinant virus replicated in silkworm larvae, which synthesized as much as 5×10^7 units (~50 μg) of interferon in their haemolymph.

We used BmNPV T3 isolate, which has been plaque-purified on BM-N cells[3]. To identify the polyhedrin gene on the viral genome of the BmNPV T3 isolate, cDNA made from messenger RNA isolated from infected fat bodies was used as a probe. In *in vitro* translation experiments in reticulocyte lysates, over 90% of the total mRNA obtained from these fat bodies at a late stage of infection was found to encode the polyhedral protein. The labelled cDNA synthesized by reverse transcriptase was hybridized to viral DNA fragments separated on an agarose gel after cleavage with restriction endonucleases. An *Eco*RI 10.5-kb fragment or a *Hin*dIII 3.9-kb fragment hybridized specifically to the probe. The *Eco*RI 10.5-kb fragment was cloned into pBR322 at the *Eco*RI site. Figure 1 shows a physical map of the resulting plasmid (pBmE36). Further hybridization experiments revealed that a 1.8-kb *Hpa*I-*Hin*dIII fragment in pBmE36 hybridized best with the probe and contained the gene for the polyhedral protein gene.

The nucleotide sequence of 1,763 bases from the *Hpa*I-*Hin*dIII fragment was determined by the dideoxy chain termination procedure[4,5]; the inferred amino-acid sequence was compared with that of the polyhedrin protein of BmNPV[6]. The starting codon, ATG, of the polyhedrin protein was found 580 bases downstream from the *Hpa*I site and the stop codon TAA was found 448 bases upstream from the *Hin*dIII site. More than 85% of the deduced amino-acid sequence was homologous to that reported by others for *Autographa californica* NPV (AcNPV)[1,2]. The differences show the degree of evolutionary

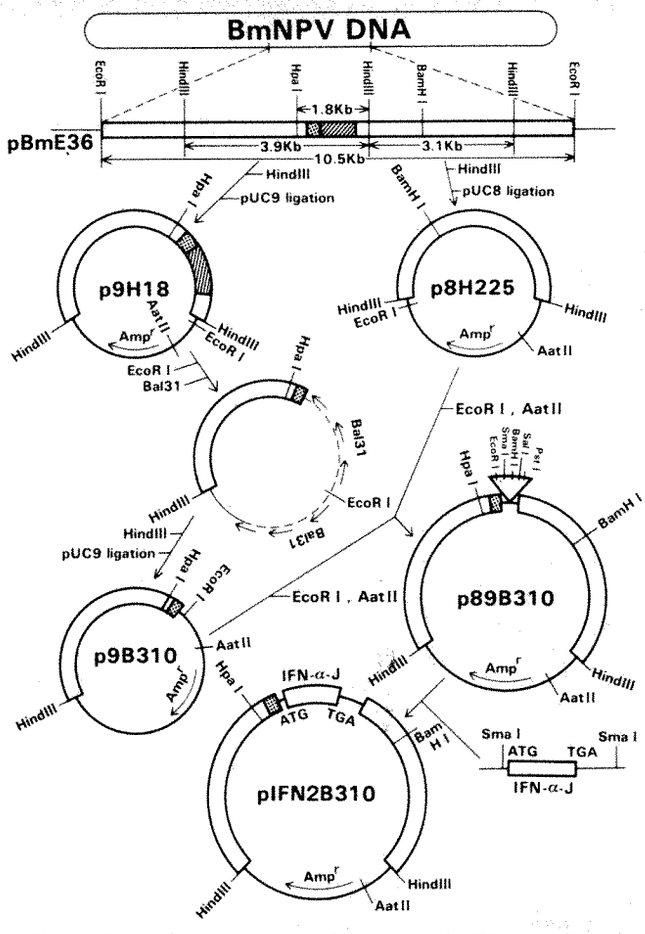

Fig. 1 Construction of vectors. The plasmid pBmE36 was cleaved with *Hin*dIII to obtain the 3.9-kb *Hin*dIII fragment containing the entire polyhedrin gene (represented by hatched blocks). This fragment was inserted into the *Hin*dIII site of pUC9. The resulting plasmid, p9H18 (50 μg), was cleaved with *Eco*RI, then incubated at 23 °C for 10 min with 50 U of *Bal*31 exonuclease. Samples (100 μl) were removed at 2-min intervals and the reaction stopped by adding 0.2 vol. 0.5 M EDTA. The samples were extracted with phenol and then chloroform, and precipitated with ethanol. The truncated p9H18 fragments were digested with *Hin*dIII, and 2.7-kb *Hin*dIII blunt-end fragments were isolated from the agarose gel. This fragment was ligated to the *Hin*dIII-*Sma*I site of pUC9 (p9B310). Sequencing of p9B310 revealed that the polyhedrin gene was digested as far as position −18 upstream of the first codon, ATG (see Fig. 2). A 3.1-kb *Hin*dIII fragment of pBmE36 was ligated to pUC8 and the resulting plasmid, p8H225, cleaved by *Eco*RI and *Aat*II to obtain the 3.5-kb fragment containing 3.1 kb of DNA downstream of the polyhedrin gene; this fragment was then ligated to the 4.7-kb *Eco*RI-*Aat*II fragment of p9B310. The resulting hybrid plasmid, p89B310, contains a polylinker (*Eco*RI, *Bam*HI, *Sma*I, *Sal*I and *Pst*I sites) just downstream of the promoter (represented by dotted blocks) of the polyhedrin gene. An IFN-α-J gene, which has *Sma*I sites just before the ATG start signal (. . . CCCGGGATG. . .), was ligated to p89B310 and cleaved by *Sma*I to construct pIFN2B310 (Fig. 2). In this plasmid, the IFN-α-J gene was oriented in the same 5′ to 3′ direction as the polyhedrin gene. The IFN-α-J gene used for this construct contained the signal peptide sequences, the coding sequences of mature IFN-α-J and the 3′-noncoding sequences (~670 bases from the stop signal, TAG) of interferon, including the signal for polyadenylation.

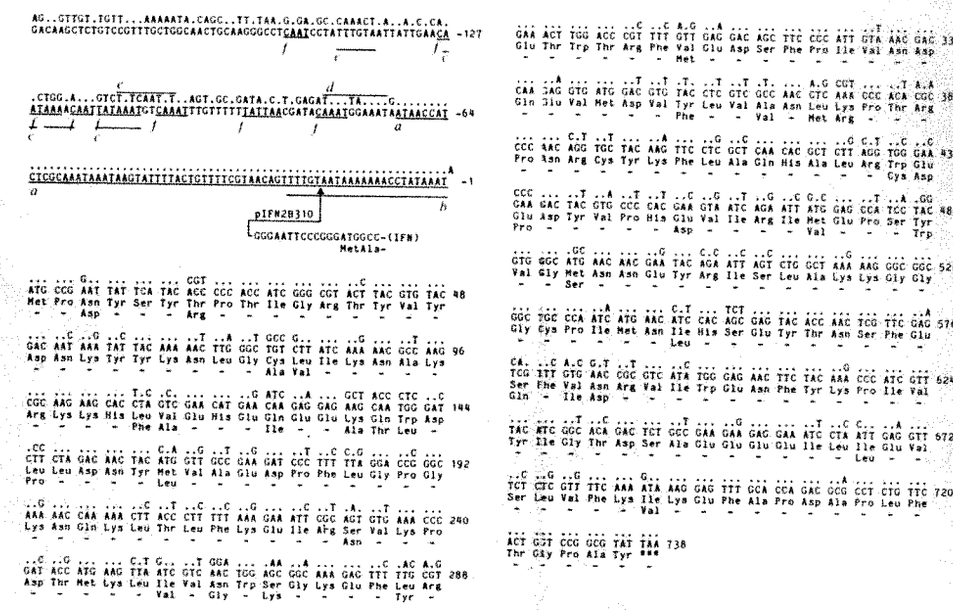

Fig. 2 Nucleotide sequence of the BmNPV polyhedrin gene and the flanking 5′-noncoding region, with the corresponding sequence of the AcNPV genome[1] shown above it. Nucleotides are numbered in the 5′ to 3′ direction beginning with the first residue of the ATG triplet encoding the initiating methionine. Dots indicate identity of the nucleotides. The deduced amino-acid sequence of BmNPV polyhedrin is shown beneath the nucleotide sequence of the BmNPV genome. The deduced amino-acid sequence of AcNPV polyhedrin is shown beneath that of PbNPV polyhedrin. Dashes indicate identical amino acids. The arrow indicates the connecting point of the polylinker in pIFN2B310.

distance between the AcNPV and BmNPV polyhedrin genes. The entire nucleotide sequence of the polyhedrin-coding region and 189 bases upstream from the translational start site are shown in Fig. 2 for both BmNPV and AcNPV[1]; 71 bases upstream of the translational start site are conserved (Fig. 2*a*). Twenty-four bases within this conserved region (Fig. 2*b*) represent an almost complete repetition of the region 110–143 bases upstream from the translational start site (Fig. 2*c*). This conserved sequence seems to be important for the high level of expression of the polyhedrin gene. There are several nucleotide changes in the coding region of the polyhedrin gene and many changes in the region upstream of the 71 conserved bases. Smith *et al.*[1] postulated that this upstream region was the promoter containing a TATA box (Fig. 2*d*) and a CAAT box (Fig. 2*e*); within the corresponding region on the BmNPV genome, we found sequences similar to TATA and CAAT boxes (Fig. 2*f*). Codon usages for the polyhedrin varied between BmNPV and AcNPV, while the amino-acid sequences of the two polyhedrins were well conserved.

A novel transfer vector carrying the 3-kb fragment containing the polyhedrin gene promoter, a polylinker derived from pUC8, and the 3.1-kb fragment downstream of the polyhedrin gene, was constructed as shown in Fig. 1. One of the recombinant plasmids used in the present study, p89B310, has the polylinker linked to 18 bases upstream from the translational start of the polyhedrin gene. A human IFN-α gene was cloned from a human gene library (provided by Dr D. G. Goeddel) using a synthetic 37-mer probe. The IFN-α gene, identified as class J[7] by sequence analysis, was fused with the plasmid p89B310 to construct the plasmid pIFN2B310 (Fig. 1).

Marker rescue was used for the insertion of the interferon gene as reported previously[1,2]. BM-N cells were co-transfected with pIFN2B310 and viral genomic DNA. Recombinant viruses, which did not produce polyhedral inclusion bodies, were isolated by plaque assay on BM-N cells from cell fluids obtained 5 days after transfection. To investigate whether the interferon gene was inserted in the expected region, DNA was extracted from a recombinant BmNPV, BmIFN2B310, and examined by hybridization analysis using labelled DNA from the interferon gene as a probe. The result confirmed that BmIFN2B310 contained the interferon gene at the expected site.

When BM-N cells were infected with the recombinant virus BmIFN2B310, the cells showed typical cytopathic effects 2 days after infection. The growth curve of BmIFN2B310 was similar to that of the wild-type isolate T3. The kinetics of interferon induction was examined in BM-N cells infected with BmIFN2B310: the titre of interferon increased to a maximum

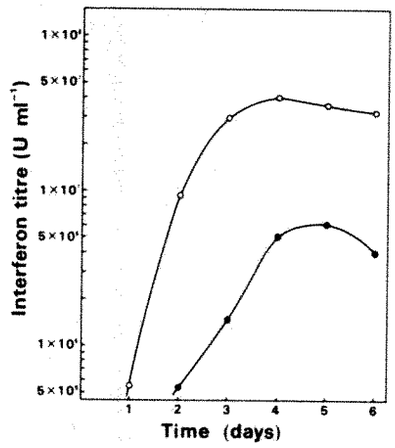

Fig. 3 Production of interferon in BM-N cells (●) and silkworm larvae (○). A solution comprising 2.5 ml of 50 mM HEPES buffer *p*H 7.1, 0.28 M NaCl, 0.7 mM Na_2CO_3 and 0.7 mM $NaHPO_4$ was added dropwise to the DNA mixture (2.5 ml of 0.25 M $CaCl_2$ containing 10 μg of BmNPV DNA and 65 μg of pIFN2B310) to form a fine precipitate. About 0.45 ml of this calcium precipitate was added to 3×10^6 cells seeded in a flask containing 4.5 ml of medium. After incubation for 12 h, the culture fluid was replaced with fresh medium and incubated for a further 4 days. A recombinant virus, BmIFN2B310, was isolated from the culture fluid and used for the expression studies. A monolayer of BM-N cells (3×10^6) was infected with BmIFN2B310 at a multiplicity of infection (MOI) of 2 plaque-forming units (PFU) per cell. 50 μl (3×10^5 PFU) of the viral solution was injected into the body cavity of silkworm larvae at an early stage of the fifth instar. At 24-h intervals after infection, the cell fluid or haemolymph was collected and assayed for interferon. The interferon activity was determined in FL cells challenged with vesicular stomatitis virus as described by Familletti *et al.*[10], and compared with that of an international standard.

of $\sim10^6$ units per ml of infected cell fluid 4 days post-infection (Fig. 3). Infected larval bodies near the abdominal appendage were pierced with a pin, squeezed slightly and the emerging haemolymph was collected in a small test tube and subjected to interferon assay. The kinetics of interferon production in the silkworm larvae was equivalent to that in infected BM-N cells; the relative activity, however, was much higher (Fig. 3). The interferon activity in both BM-N cells and larvae decreased slightly at 6 days post-infection. The activity in the haemolymph

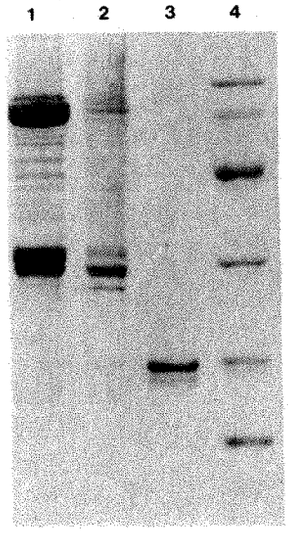

Fig. 4 Purification of the interferon produced in the silkworm. Lane 1, 5 μl of uninfected haemolymph; lane 2, 5 μl of BmIFN2B310-infected haemolymph; lane 3, 5 μl (20 μg protein) of the fraction eluted from the affinity chromatography column; lane 4, 5 μg of each relative molecular mass (M_r) marker (phosphorylase *b*, M_r 94,000 (94K); albumin, 67K; ovalbumin, 43K; carbonic anhydrase, 30K; trypsin inhibitor, 20.1K; α-lactalbumin, 14.4K).

Methods. About 10 ml of haemolymph from 15 silkworm larvae infected with BmIFN2B310 was collected as described in the text. The haemolymph was mixed with an equal volume of fresh medium for BM-N cells and centrifuged at 12,000 r.p.m. for 5 min. The supernatant was applied to an affinity Sepharose 4B column with monoclonal antibody against human IFN-α and washed several times with a solvent containing 0.2 M sodium acetate (*p*H 7.3), 0.5 M NaCl and 20% glycerol. The interferon was eluted from the column with a solvent containing 0.1 M citric acid (*p*H 2.2), 0.5 M NaCl and 20% glycerol, and concentrated ~10-fold. Samples were analysed by SDS-polyacrylamide gel electrophoresis on a 10% gel. The gel was stained with Coomassie brilliant blue R.

was at a maximum (4×10^7 U ml^{-1}) at day 4. The highest recorded level of human IFN-α produced in a eukaryotic system is 4×10^5 U ml^{-1} (for mouse cells with a bovine papillomavirus vector[8]).

The haemolymph from the infected silkworm was affinity-purified by column chromatography, then analysed by SDS-polyacrylamide gel electrophoresis. From 10 ml of infected haemolymph (250 mg protein) collected from 15 larvae, 0.3 mg of interferon was eluted. The specific activity (U mg^{-1} protein) increased from 2.1×10^5 to 1.0×10^8; the yield was higher than 50%. The eluted sample, separated on gels, was stained with Coomassie brilliant blue, which revealed a major band of relative molecular mass 19,500 (Fig. 4). The protein fraction corresponding to this band was extracted from the gel and showed interferon activity. An immune blot analysis indicated that labelled antibody to human IFN-α reacted exclusively with the major band. N-terminal amino-acid sequence analysis (11 amino-acid residues) of the major fraction established its identity to human IFN-α. These findings show that there is no difference between interferon produced in silkworm and that made in mammals, hence the signal peptide sequence can be removed in the same manner as in mammalian cells. Purification of IFN-α made in silkworm is just as easy as for that produced in mammalian cells.

The circulatory system in the silkworm is 'open', in contrast to the 'closed' system of vertebrates. About 30% of the total volume of the silkworm larva consists of the body cavity filled with haemolymph. The haemolymph also represents a storage tissue, for example, the major proteins of the silkmoth *Hyalophora cecropia*, called storage proteins, accumulate in the haemolymph at the late larval stage[9]. The interferon produced is probably deposited in the haemolymph in a similar way without degradation by endogenous enzymes and can be purified without apparent loss of activity.

The present study represents the first report of a high level of synthesis of a foreign gene product in a living animal. The silkworm has been improved for mass culture for several thousand years, and it is now possible to maintain unlimited amounts of silkworm under the control of computerized machines. The system described here, which uses these insects, thus offers an exciting alternative for mass production of foreign gene products.

We thank Drs J. H. Strauss, E. S. Strauss, Y. Tanada and W. Ostertag for critical reading of the manuscript; Drs R. Dohmori, Y. Marumoto, I. Ishida and Y. Tonooka for discussions; and Miss T. Chika and Miss I. Sakamoto for the interferon assay.

Retrovirus-induced *de novo* methylation of flanking host sequences correlates with gene inactivity

The pattern of DNA methylation changes during development of eukaryotes, and hypomethylation frequently correlates with gene expression (for reviews see refs 1–4). A causal relationship between hypermethylation and gene inactivity has been established for retroviral genomes which are methylated *de novo* when inserted into the germ line of mice (ref. 5; for review, see ref. 6). The mutual interaction of the provirus with the host genome can influence virus expression[7] and can result in inactivation of the host gene by insertional mutagenesis[8]. We report here that the insertion of a provirus can change the methylation pattern of the host DNA. Sequences flanking the provirus become methylated *de novo* within 1 kilobase (kb) of the integration site. In Mov-13 mice, which carry a lethal mutation of the α1(I) collagen gene[9,10], *de novo* methylation of host DNA is associated with a change in chromatin conformation[11]. This suggests that virus-induced DNA methylation can alter DNA–protein interactions and thereby interfere with correct gene activation during embryonic development.

The Mov substrains of mice, each carrying a single and highly methylated Moloney murine leukaemia virus (M-MuLV) genome at a distinct mendelian locus[7], were used to study the interaction of a provirus with its flanking host sequences. DNAs from parental control mice and from Mov mice were compared to investigate whether insertion of virus affects the methylation state of its flanking sequences. Methylation patterns were analysed by digesting DNAs from different developmental stages with methylation-sensitive restriction enzymes, followed by hybridization with probes representing the viral preintegration site. Here we report the results obtained with Mov-7, Mov-9 and Mov-13 mice.

‡ Present address: Salk Institute, PO Box 85800, San Diego, California 92138, USA.

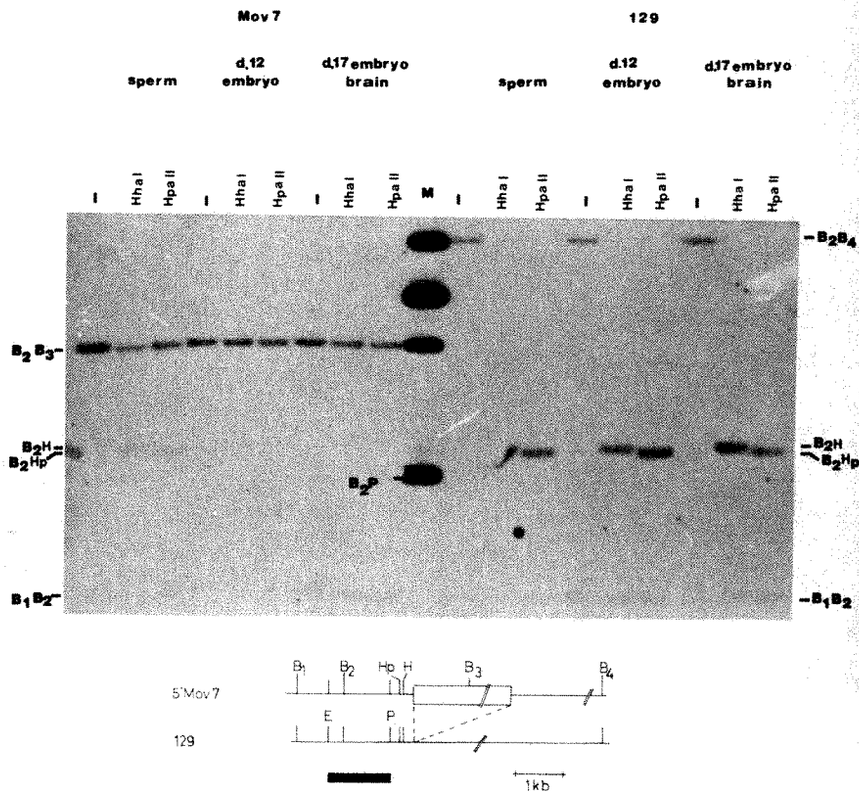

Fig. 1 Methylation of sequences 5′ of the integration site of the M-MuLV genome in Mov-7. DNAs were prepared from mature sperm, from pools of embryos and embryonic tissues, and analysed with restriction enzymes as described elsewhere[14]. Samples (20 μg) were digested with *Bst*EII (B) and in addition with either *Hha*I (H) or *HPA*II (Hp), fragments were separated on a 1.4% agarose gel, transferred to nylon membrane and hybridized with nick-translated[25] plasmid p7-1-1 which carries the *Pst*I(P)-*Eco*RI(E) fragment (solid bar in map at bottom) from the 5′-flanking region of the Mov-7 M-MuLV genome[26]. Cleavage products were mapped by comparison with the sizes of marker (M) bands derived from plasmid p7-2, which carries the Mov-7 provirus (open bar in map) within flanking cellular sequences. Digestion of p7-2 with *Bst*EII and *Bst*EII plus *Pst*I generated fragments B_2B_3 and B_2P, respectively, and, in addition, fragments of 8.6 and 4.7 kb, respectively, containing vector sequence. Partial methylation at sites H and Hp in Mov-7 sperm was indicated by the loss of intensity of band B_2B_3 and the appearance of weakly hybridizing bands migrating slightly above band B_2P (see map). The complete digestion of bands B_2B_4 (which were not transferred quantitatively to the nylon membrane), the high intensity of the cleavage products B_2H and B_2Hp, and the absence of other products, indicated lack of methylation at sites H and Hp in the DNAs from 129 mice.

Figure 1 shows *Bst*EII digests of DNA from sperm, and from day 12 and day 17 embryos of the Mov-7 and parental 129 mouse strains, which were hybridized to a probe representing 5′-flanking host sequences. This yielded the virus/cell junction fragment B_2B_3 in Mov-7 and fragment B_2B_4 spanning the integration site in 129 DNA. The junction fragments from day 12 and day 17 embryos of the Mov-7 strain were resistant to cleavage by *Hha*I and *Hpa*II, indicating complete methylation of the sites Hp and H in the 5′-flanking region (see the map in Fig. 1). A slightly lower level of methylation in sperm of Mov-7 mice resulted in digestion of the Mov-7-specific *Bst*I fragment and generated weakly hybridizing cleavage products. In contrast, both sites were completely unmethylated before virus integration, as demonstrated by the amount and the size of the *Hha*I and *Hpa*II cleavage products in 129 DNA (see Fig. 1 legend).

Similarly to Mov-7, the sequences flanking the provirus in Mov-13 mice were unmethylated before virus integration and became methylated after integration. Figure 2*a*, *b* shows the analysis of the 5′-flanking sequences and Fig. 2*c* that of the 3′-flanking sequence; the DNA bands shown are designated by letters corresponding to the respective restriction enzyme recognition sites indicated on the map. Because Mov-13 mice are heterozygous for the virus insertion[8], the probes recognize the virus-carrying and the normal allele in these mice and only the normal allele in the C57BL parental strain. Hybridization with probe A (see map in Fig. 2), which identifies sequences 5′ of M-MuLV integration site of the Mov-13 strain, revealed identical restriction patterns in *Bst*EII/*Ava*I- (Fig. 2*a*), *Bst*EII/*Hha*I- (Fig. 2*b*) and *Bst*EII/*Hpa*II (data not shown)-digested DNAs from sperm of both Mov-13 and C57BL/6 parental mice. The intensity and size of the digestion fragments (see Fig. 2 legend) indicated the absence of methylation at all seven sites within 1 kb of 5′ cellular sequences before and after provirus insertion (see Fig. 3). The same patterns as in sperm DNAs were present in the DNAs from day 12 embryos of C57BL/6 and Mov-13 mice (Fig. 2*a*, *b*). However, additional bands of higher relative molecular mass in Mov-13 embryo DNA indicated methylation at four sites present within 700 base pairs (bp) 5′ of the virus integration site (see Fig. 2 legend). An analysis of a 5′ virus/cell junction fragment, by *Kpn*I digestion of the same DNA, was used to distinguish between the two different chromosomes in the Mov-13 embryos, and localized the *de novo* methylated sites exclusively to the Mov-13 allele (Fig. 3).

The *Bam*HI-*Bgl*II cell virus junction fragment recognized by probe B served to determine the methylation of sequences 3′ of the provirus in the Mov-13 allele (Ba-Bg) and in the allele from C57BL/6 parental mice (Ba_1Bg; see Fig. 2*c*). *Ava*I and *Hpa*II cleaved these fragments completely in sperm DNA from Mov-13 and C57BL/6 mice, generating fragments that indicated non-methylation of the *Ava*I site and of two *Hpa*II sites within 300 bp 3′ of the provirus. The same three sites were completely methylated in the Mov-13 allele of day 12 embryos, as the virus/cell junction fragment was nearly resistant to cleavage. In contrast, the normal allele in both Mov-13 and C57BL/6 parental mice was not methylated at two sites, and only partially methylated at the one other site (see Fig. 2 legend; Fig. 3). The single *Hha*I site in this region was analysed similarly by *Sst*I digestion. The methylation at this site in sperm and day 12 embryos was partial in the C57BL/6 parental allele and complete near the Mov-13 provirus (Fig. 3).

The provirus in Mov-9 mice is flanked by cellular sequences which are methylated in day 12 embryos of the 129 parental mice as well as of the Mov-9 strain. Figure 4 shows that five CpG sites within 4 kb of cellular sequences at the 3′ end, and one site at the 5′ end, are fully methylated in embryonic DNA from the 129 parental strain. Provirus integration at the Mov-9 locus did not change the high level of methylation of the flanking host sequences, except for the *Hha*I site 5′ of the provirus, which is partially methylated in sperm of the Mov-9 strain and unmethylated in sperm of the parental 129 strain (Figs 3, 4).

Figure 3 summarizes our results. The cellular sequences at the respective preintegration sites of the Mov-7 and Mov-13 provirus were unmethylated in sperm as well as in somatic cells from day 12 and day 17 embryos and from adult mice of both the 129 and C57BL/6 parental strains. Analysis of somatic cells showed that provirus integration resulted in complete methylation of all tested sites in 1 kb of flanking sequences at both loci. The methylation status of sites that were farther than 1 kb away

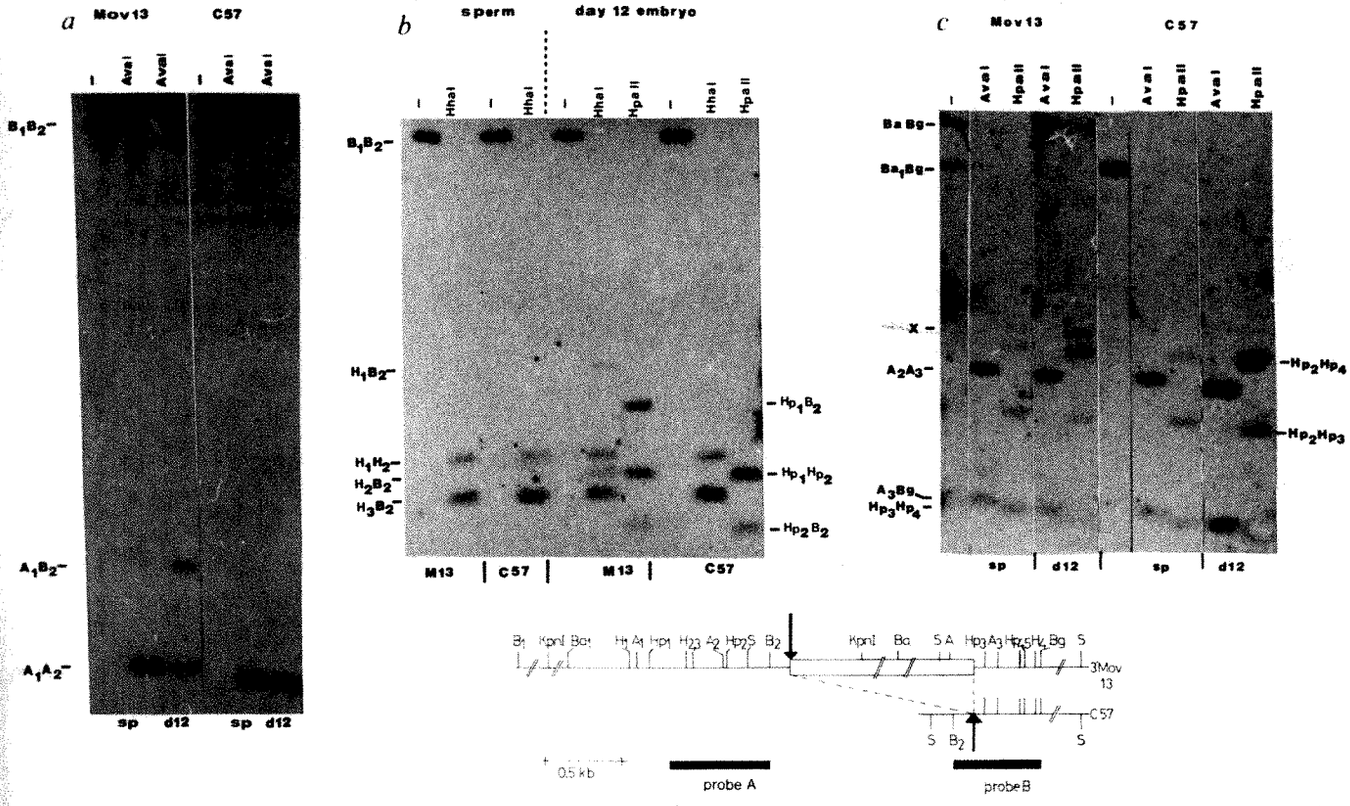

Fig. 2 Methylation of cellular sequences flanking the integration site of the Mov-13 provirus. DNAs from sperm and day 12 embryos of heterozygous Mov-13 × C57BL/6 mice[7] carrying a single M-MuLV provirus (open bar in map) and from uninfected C57BL/6 mice were prepared and analysed as described in Fig. 1 legend. The methylation of cellular sequences 5′ of the proviral integration site (vertical arrow) was determined in 20-μg samples of *Bst*EII (B)-digested DNAs with *Ava*I (A) (***a***), *Hha*I (H) and *Hpa*II (Hp) (***b***), using probe A (black bar) derived from cloned sequences of the Mov-13 locus[10]. The nucleotide sequence and map from this region[10] were used to deduce the recognition sites of the methylation-sensitive enzymes (see map) and cloned subfragments of the Mov-13 locus served as length markers (not shown) to map the cleavage sites of these enzymes in the mouse DNAs. Thus, the lengths of the *Ava*I cleavage products in *a* indicated the absence of methylation at sites A_1 and A_2 in C57BL/6 chromosomes generating band A_1/A_2, and methylation at site A_2 in the Mov-13 allele of day 12 embryos was indicated by band A_1B_2. Band A_2B_2 was too small to be detected in this analysis. Similarly, there was Mov-13-specific methylation at sites H_2, H_3 and Hp_2 but not at sites H_1 and Hp_1, as deduced from bands H_1B_2, H_2B_2 and Hp_1B_2, respectively, which appeared in embryonic DNA (*b*). Complete digestion of Mov-13 and C57BL/6 DNAs indicated the absence of methylation at all *Hha*I and *Hpa*II sites in sperm (*b*, *Hpa*II analysis not shown). ***c***, The 3′ cellular sequences were analysed with probe B (black bar), a *Bst*EII-*Bgl*II fragment from the *Mov-13* locus[10]. The *Bam*HI-*Bgl*II virus/cell junction fragment of 2.3 kb (Ba-Bg) and the corresponding cellular fragment of 1.7 kb (Ba_1Bg) were further digested with *Ava*I and *Hpa*II. The sizes of the cleavage products derived from DNAs of Mov-13 and C57BL/6 sperm indicated the absence of methylation at sites A_3, Hp_3 and Hp_4 in both alleles. The virus/cell fragments, generated from cleavage at the unmethylated 3′ viral sites A and Hp (see ref. 14) were not detectable due to their small stretch of homology with probe B (see map). In day 12 embryos, a fragment of 710 bp showed partial methylation at site Hp_3 in the C57BL/6 allele, and the resistance of fragment Ba-Bg to secondary digestion indicated methylation at all sites 3′ of the provirus. Fragment X was generated in DNA from Mov-13 embryos as a result of partial *Hpa*II cleavage at a site in the 3′ enhancer region of the provirus, which becomes preferentially demethylated during mouse development[14]. The methylation at site H_4 was determined in a similar manner by *SSt*I (S) and *Hha*I digestion using probe B (not shown; see Fig. 3).

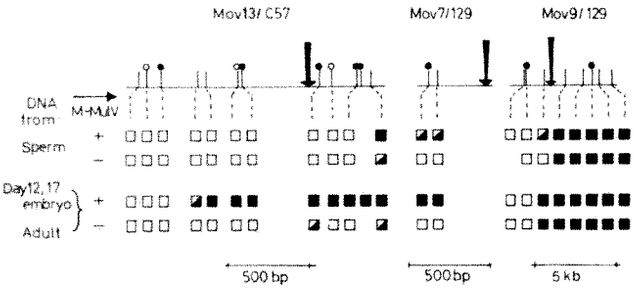

Fig. 3 The methylation at *Hha*I(|), *Ava*I(♀) and *Hpa*II(♀|) sites around M-MuLV integration sites (vertical arrows) was determined in Mov-7, -9 and -13 mice (+) and in homologous sequences of parental mouse strains (−) as described in the legends of Figs 1, 2 and 4. Filled, half-filled or open boxes indicate ≥80%, 20–80% or <20% methylation, respectively, of the individual sites. The horizontal arrow shows the direction of viral transcription from the 5′ to the 3′ end. The data for day 17 embryos and adult mice represent liver and brain or brain and kidney, respectively; the analysis of 5′ cellular sites from Mov-9 mice is described elsewhere[14].

from the integration site was not affected by provirus integration. The sequences flanking the Mov-13 provirus, which represent the 5′ end of the α1(I) collagen gene[10], were completely unmethylated in sperm, indicating that virus insertion induced *de novo* methylation of unique cellular sequences during embryogenesis. So far, *de novo* methylation has been observed only in repetitive sequences[12,13] or with proviral or cellular sequences introduced into transgenic mice[14,21]. The lower level of methylation in sperm than in somatic cells of Mov-13 mice may indicate either germline-specific lack of *de novo* methylation or specific demethylation at these sites during spermatogenesis. The relative hypomethylation of satellite DNA in extraembryonic as opposed to embryonic tissues[12] is consistent with the notion that *de novo* methylation occurs after the blastocyst stage, when these cell lineages have separated.

In contrast to Mov-7 and Mov-13, the provirus in Mov-9 mice has integrated into a hypermethylated region, the methylation status of which was not detectably affected by the insertion. A similar result was found for Mov-2 and Mov-3 (unpublished) and Mov-10 mice[14].

De novo methylation of retroviral sequences introduced into mouse zygotes, early mouse embryos or embryonic carcinoma

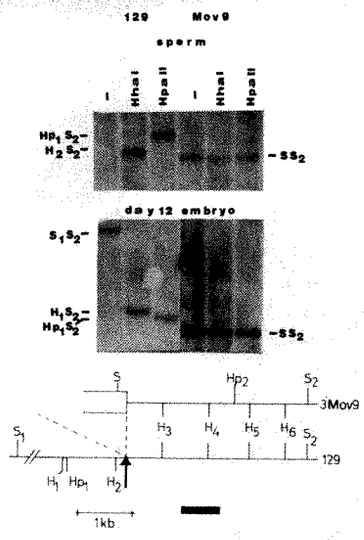

Fig. 4 Methylation of cellular sequences flanking the integration site of the Mov-9 provirus. DNAs from Mov-9 (ref. 7) and uninfected parental 129 mice were prepared and analysed with restriction enzymes as described in Fig. 1, legend, using plasmid p9-1-2, which carries sequences (black bar in map) 3′ of the integration site (vertical arrow) of the Mov-9 provirus (open bar; see ref. 26). DNA samples (20 μg) were digested with *Sst*I (S), generating the viral junction fragment SS_2 in Mov-9 DNAs and fragment S_1S_2 which spans the integration site in the 129 alleles. In 3′-flanking sequences the *Hha*I (H) and *Hpa*II (Hp) sites were methylated in Mov-9 mice, as seen by the resistance of band SS_2 to secondary digestion. The gel position of this fragment was used to localize, in 129 mice, the unmethylated sites Hp_1, H_2 or H_1 in sperm and day 12 embryos, respectively (see map).

cells correlates with transcriptional inactivity, whereas the absence of *de novo* methylation in somatic cells correlates with gene expression (refs 15–20; see ref. 3 for review). The present results show that a functional provirus becomes repressed even when integrated into a chromosomal region which, as in Mov-13 mice, has all the characteristics of active gene expression, that is, hypomethylation and the potential to develop an open chromatin configuration[11]. Thus, the integration of retroviruses may lead to altered chromatin structures that allow *de novo* methylation. The molecular basis for both provirus and host gene suppression may be the maintenance of these structures due to their methylation. Non-retroviral genes which have been introduced into the germ line of mice are often not expressed[21–24]; it remains to be seen whether this is correlated with similar changes in chromatin structure and methylation pattern as described here for Mov mice.

We thank A. Schnieke and K. Harbers for plasmids; H. Weiher for critical comments; and K. Haase for technical assistance. This work was supported by grants from the Deutsche Forschungsgemeinschaft, the Stifttung Volkswagenwerk and the NIH, USA. A viral enhancer element specifically active in human haematopoietic cells

Luitgard Mosthaf, Michael Pawlita* & Peter Gruss

Zentrum für Molekulare Biologie, Universität Heidelberg, Im Neuenheimer Feld 364, D-6900 Heidelberg, FRG
* Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg, FRG

One particular class of DNA regulatory elements, the enhancers or activators, can, relatively independently of distance and orientation, dramatically increase the transcriptional activity of homologous and heterologous promoters located in *cis* (see refs 1–3 for reviews, also refs 4–6). Sequence differences between various heterologous enhancers[7,8] may explain their apparent host- and/or tissue-specific action[9–15]. Furthermore, differences in the transcriptional control elements may contribute to viral tropism. At least for murine leukaemia virus isolates, thymotropism and leukaemogenicity have been attributed to alterations within the viral long terminal repeat[15–17], which harbours their enhancers and other transcriptional control elements. We report here the identification of a viral enhancer element possessing a very restricted tissue range. The enhancer is active in all human cells of the haematopoetic system tested, but not in cells of fibroblast or epithelial origin.

In the recently discovered lymphotropic papovavirus (LPV)[18], progeny production is restricted to continuously growing cells of primate B-lymphocyte origin[19–21], and sequence analysis[22] shows that the LPV genome has a structure typical of all other known polyomaviruses[23] (Fig. 1). In addition to early and late regions encoding virus-specific proteins, a noncoding region of ~700 base pairs (bp) is situated between the first early and late translational start codons and harbours several sets of repeated sequences. A large set of direct repeats (106 bp) presumably contains the origin of replication (Fig. 1)[22,23]. Because it is present twice on the cloned LPV DNA, this clone was probably produced from a natural variant carrying two origins of replication; this notion was confirmed experimentally by removing one of the direct repeats, for, despite this deletion, the LPV genome retains its viability (M.P., unpublished). A smaller (63 bp) sequence set lies to the late side of the 106-bp fragment. It is duplicated once flanking the origin proximal to the early region, and is present as a monomer flanking the distal origin (Fig. 1).

Several indications prompted us to search for an enhancer element in this smaller repeat. Its position on the genome is similar to that of all other known papovavirus enhancers[4,24–28], with the exception of papillomaviruses[29], and a sequence resembling the enhancer core sequence of simian virus 40 (SV40)[7] and the mouse immunoglobulin constant-region heavy-chain gene (C_μ)[10] is present within the 63-bp repeat. To test for enhancer function, a 234-bp *Hae*III fragment that included the 63-bp repeat (Fig. 1) was cloned into the pA10-CAT2 plasmid[9],

Table 1 CAT activity in cells of haematopoietic, epithelial and fibroblast origin after transfection with pSV2-CAT, pLPV-5′-CATs or pCμ-5′-CATs DNA

Cell line	Origin	CAT activity pSV2-CAT	pLPV5′-CATs	pCμ5′-CATs

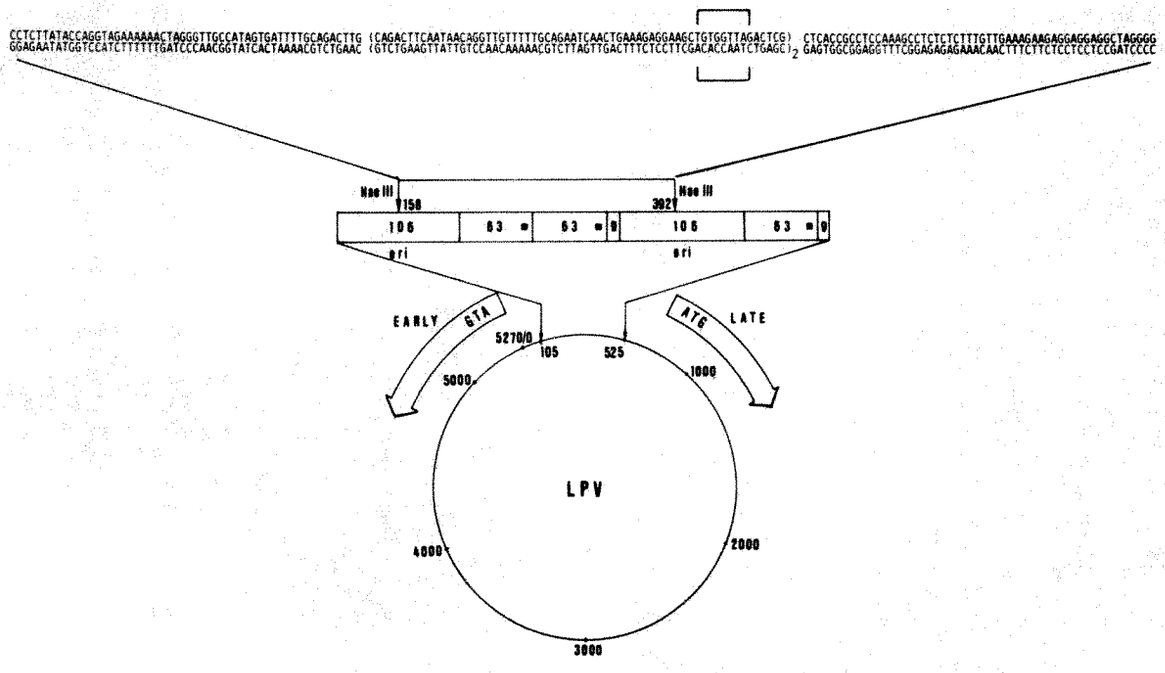
The transfection procedures and CAT assays were done as described in Fig. 2*b* legend. After chromatography and autoradiography, the spots containing the acetylated (CM-Ac) and non-acetylated (CM) forms of ^{14}C-chloramphenicol were cut out, placed in scintillation liquid and counted. The percentage of CM-Ac radioactivity in the total (CM−Ac+CM) was determined. –, No enhancement; +, 5-fold enhancement; ++, 5–20-fold enhancement; +++, >20-fold enhancement. The percentage of acetylated chloramphenicol in cells transfected with pA10-CAT2 (enhancer minus constructions, see Fig. 2*a*) was taken as the denominator and an enhancement factor was calculated for cells transfected with constructions carrying SV40, LPV and C_μ enhancers, respectively. ND, not done.



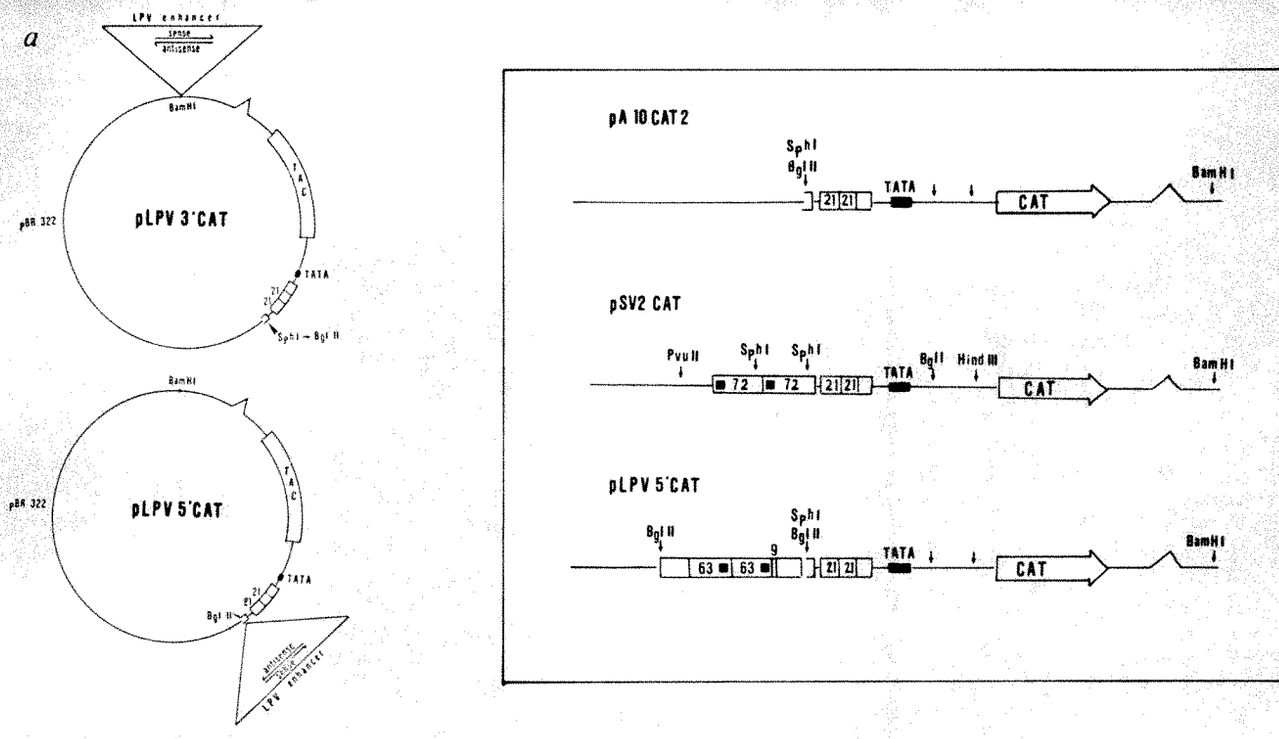


Fig. 1 Genomic organization of lymphotropic papovavirus (LPV). The early and late coding regions of LPV DNA are separated by a stretch of noncoding sequences of ~700 bp. This region contains several sets of direct repeats as represented by the open boxes (see text for further details). The numbers of base pairs which are homologous in each repeat are indicated by the numbers in the open boxes. A 234-bp *Hae*III fragment, containing the 63-bp repeat, was cloned into plasmid pA10-CAT2 (see Fig. 2). The sequences within the 63-bp repeat which resemble enhancer core nucleotides[7] are indicated by solid squares. The complete nucleotide sequence[22] of the *Hae*III fragment is given at the top, with the enhancer core nucleotides indicated by brackets.

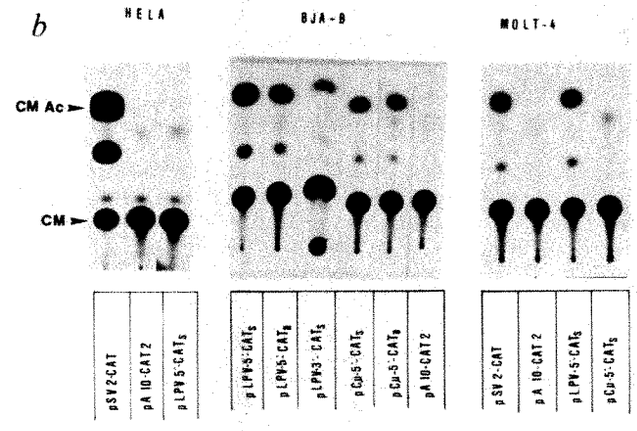

Fig. 2 *a*, Construction of pLPV-5′-CATs, pLPV-5′-CATa and pLPV-3′-CATs DNAs. Enhancer core nucleotides are indicated by closed boxes. *b*, CAT activity of BJA-B, MOLT-4 and HeLa cells after transfection with pLPV-CAT, pCμ-5′-CAT or pSV2-CAT DNA.

Methods. *a*, The 234-bp *Hae*III fragment (see Fig. 1) of LPV was excised, ligated to *Bgl*II linkers and cloned upstream of the CAT gene in the *Bgl*II site of pA10-CAT2 (ref. 9) in either orientation (sense or antisense). Another construction was made, containing the *Hae*III fragment downstream of the CAT gene in the *Bam*HI site of pA10-CAT2 (pLPV-3′-CATs). pA10-CAT2 and pSV2-CAT, which were also used for transfection experiments, have been described previously[9,30]. *b*, BJA-B cells[35] and MOLT-4 cells[33] were grown in RPMI 1640 medium supplemented with 10% fetal calf serum (FCS). HeLa cells were grown in Dulbecco's modified Eagle's medium supplemented with 10% FCS. Cell transfection was carried out by the DEAE-dextran method[33,34]. The cells (5×10^6) were washed twice with TBS[14] and subsequently incubated at room temperature for 30 min with a mixture containing 10 μg of plasmid DNA in 50 μl TE (15 mM Tris, 1 mM EDTA), *p*H 7.8, 250 μl TBS and 300 μl DEAE-dextran (1 mg ml^{-1}). After incubation, the cells were washed again with TBS, resuspended in fresh medium, incubated at 37 °C, 5% CO_2 and 48 h after transfection, collected to determine CAT activity. The CAT assay was performed as described by Gorman *et al.*[30] with a few minor modifications. Standard enzyme reactions were performed with 100 μl of a total of 150 μl extract and were incubated for 90 min at 37 °C. The assay mixture final volume (171.5 μl) contained 0.2 μCi ^{14}C-chloramphenicol ($\sim2\times10^5$ c.p.m.) and 4 mM acetyl-CoA in 0.25 M Tris-HCl buffer (*p*H 7.8). The reactions were stopped by extraction with 0.4 ml ethylacetate. The ^{14}C-chloramphenicol was dried and resuspended in 10 μl ethylacetate; its derivatives were separated by ascending TLC (0.25 mm silica gel) with a chloroform/methanol (95:5) solvent phase. The chromatography plates were then exposed to Kodak XAR-5 film for 12–24 h.

which can serve as an enhancer assay system as discussed previously[9] (see Fig. 2*a* legend for details). Thus, activation of this transcriptional unit can be estimated through the production of both RNA and chloramphenicol-acetyl-transferase (CAT) activity, the amount of which is dependent on the enhancer inserted[9,30]. The LPV fragment was cloned at the 5′ end of the CAT gene into a *Bgl*II site in opposite orientations (pLPV-5′-CATs, pLPV-5′-CATa (Fig. 2*a*). ('s' signifies sense, indicating that the orientation of the LPV fragment with the CAT gene is the same as it is with the early coding region of LPV; 'a' signifies the opposite, or antisense, orientation.) Similarly, the LPV fragment was inserted into a *Bam*HI site, located 3′ of the SV40 polyadenylation signal (pLPV-3′-CATs). As a control, similar plasmids were constructed carrying the known enhancer of C_μ. The *Xba* I-E fragment of the mouse C_μ gene[10] was excised and cloned in both orientations into an *Xba*I site of a test plasmid (pCAT-2 polylinker)[31,32]. No difference in enhancer activity was detected whether pA10-CAT2 or pCAT2-polylinker was used as a recipient for the same enhancer DNA fragments.

To test for the functional activities of the various plasmid constructions, purified DNA was introduced into eukaryotic cells using DEAE-dextran as facilitating agent[33,34]. As LPV was adapted to grow lytically in the human B-lymphoma line BJA-B (ref. 35), these cells were chosen as recipients for the first series of transfection experiments. Little or no CAT activity was detected in BJA-B cells transfected with pA10-CAT2 (Fig. 2*b*), but when the 234-bp LPV fragment was inserted at the 5′ end of the SV40 promoter region, the cells produced CAT, as demonstrated by the conversion of chloramphenicol (CM) into its acetylated forms (CM-Ac) (Fig. 2*b*). The conversion rate is independent of the orientation of the LPV fragment, as both the sense (pLPV-5′-CATs) and antisense (pLPV-5′-CATa) insertions gave similar conversion rates. Also, introduction of the 234-bp LPV fragment in the sense orientation at the 3′ end of the polyadenyl-

ation signal produced activation of the transcriptional unit, thus fulfilling the criteria described for most other viral enhancer sequences. The relative level of enhancement at the 3′ end (Fig. 2*b*; pLPV-3′-CATs), however, was three- to fourfold less than for the 5′ construction. We are investigating the reason for this reduction.

The relative strength of the transcriptional activation by the LPV enhancer was estimated by performing a control experiment to measure the activity mediated by the well-characterized C_μ enhancer[10]. Insertion of the *Xba* I-E fragment at the 5′ end of the SV40 promoter elements resulted in the production of CAT, independent of orientation (pCμ-5′-CATa, s), at levels comparable with those of the respective LPV-containing plasmids in BJA-B cells (Fig. 2*b*).

To demonstrate that the CAT results directly reflect the CAT transcriptions present, we performed S_1 nuclease analysis of the CAT RNA to map the 5′ ends. Although we found that the plasmid containing the LPV enhancer showed the same RNA start sites as the well-characterized plasmid pSV2-CAT that contains the SV40 enhancer (data not shown), the bands detected were very weak, preventing us from obtaining quantitative data. Therefore, the following experiments were carried out using the CAT assay, as this seemed more sensitive.

In investigating the host- and cell-type specificity of the LPV enhancer, because LPV seems to infect only cells of B-cell lineage, we used a human lymphoma cell line of T-cell origin (MOLT-4)[36] as a recipient for various plasmid constructions. Only the LPV 234-bp fragment and the SV40 enhancer[9,22,30] activated CAT production in MOLT-4 cells, and no enzyme production was detected after transfection of the plasmid carrying the C_μ enhancer (pCμ-5′-CATs) or the recipient plasmid without insert (pA10-CAT2) (Fig. 2*b*). A similar result was obtained after transfection of the plasmid constructions into two additional established human cell lines (JM-1, CEM-C7) with T-cell characteristics (Table 1). Thus, although the C_μ enhancer is active in cells of B-lymphoid origin, it does not seem to increase the transcription of transfected recombinant plasmids in the human T-cell lines used. On the other hand, the cell specificity of the LPV fragment seems less strict because LPV was also active in T cells and in several other non-B-non-T lymphoid cell lines (Table 1), whereas none of these cell types responded to the C_μ enhancer.

Because all the cell lines used in these studies have a transformed phenotype, it was essential to eliminate the possibility that transformation is required for LPV enhancer activity. We therefore transfected peripheral blood cells stimulated with concanavalin A and pokeweed mitogen and found that these cells recognize both LPV and C_μ enhancers (Table 1). Surprisingly, transfection of two mouse myeloma-derived cell lines, X63Ag8 (ref. 37) and 15E1 (B. Georg-Fries, personal communication), with pLPV-5′-CATs did not yield any CAT, although parallel transfections with pCμ-5′-CATa showed marked CAT activity (Table 1).

To determine whether the activity of the LPV activator is restricted to haematopoietic cells, we analysed the enhancer activities after transfection of test plasmids into several established and primary cell lines (Table 1). Using the HeLa cell line, which is of epithelial origin, we found that, in transfection experiments the LPV enhancer (pLPV-5′-CATs) did not stimulate activity in these cells, whereas SV40 enhancer (pSV2-CAT) yielded large amounts of CAT (Fig. 2*b*, Table 1). A similar difference between LPV and SV40 enhancers was found in secondary human foreskin fibroblasts, CV-1 cells and primary hamster embryonic cells. To our surprise, the LPV-transformed[38] hamster embryonic cell line responded to both LPV and C_μ enhancers. It is unclear whether this results from a specific cell type, selected by transformation with LPV, or whether it results from the presence of a *trans*-acting factor[39] provided directly or indirectly by LPV T-antigen.

Our results indicate that a 234-bp fragment from the LPV genome contains an enhancer element. This selected fragment contains a 63-bp repeat harbouring the putative enhancer core sequence[7]. Although probable, it remains to be shown that the transcriptional enhancement is mediated by this 63-bp repeat. Interestingly, this viral enhancer element exerts activity only in cells of human haematopoietic origin and in this respect differs from the mouse immunoglobulin heavy-chain gene enhancer[10] which, in our hands, is active only in B-lymphoma cells. However, recent experiments by others indicate that the mouse C_μ enhancer is active in some T-cell lines of mouse origin (W. Schaffner and D. Baltimore, personal communication). This result could be explained by host-range differences and it is interesting that the LPV enhancer seems to show a host-range effect in addition to the cell-type specificity (Table 1). Preliminary evidence indicates that the inability of LPV to produce progeny in T lymphoblasts or other haematopoietic cells results from a lack of adsorption and/or uncoating of LPV particles (M.P., unpublished). Taken together, our data are compatible with the previous observation that enhancers interact with cellular molecules (refs 40–42 and P. Sassone-Corsi and P. Chambon, personal communication). However, only the presence of more than one class of cellular factors could explain our data satisfactorily. Our present research is directed towards the identification of such factors.

We thank G. Khoury and H. zur Hausen for helpful suggestions, A. Colberg-Poley for valuable comments on the manuscript, H. Schöler for mapping the CAT RNA, A. Ziegler, G. Hämmerling, K. Takada, B. Georg-Fries, K. Takemoto and G. Bornkamm for cell lines, W. Schaffner for providing the C_μ plasmid, and R. Franklin for typing the manuscript. A novel immune system against bacteriophage infection using complementary RNA (micRNA)

The 'operon' theory of gene regulation[1], in which protein repressor molecules bind to the operator site of a gene to prevent its transcription, is now well established. Recently, however, cases have been discovered in which gene expression is regulated by complementary RNA molecules that are able to bind to the transcripts of particular genes and consequently prevent their translation[2–5]. For example, the synthesis of OmpF protein (a major outer membrane protein) in *Escherichia coli* is regulated by a short RNA complementary to a region of *ompF* RNA encompassing the 'Shine–Dalgarno' sequence[6] and the translation initiation codon[2,3]. This RNA has been termed micRNA (messenger-RNA-interfering complementary RNA), and its discovery has prompted us to construct an artificial micRNA system designed to regulate gene expression in *E. coli*[7]. A given target gene can be repressed by artificially producing an RNA (micRNA) complementary to the mRNA encoded by that gene. A micRNA system has also been used successfully in tissue-cultured mammalian cells[8,9]. The use of artificial micRNAs to specifically regulate individual genes has great potential as a novel cellular immune system for blocking bacteriophage or virus infection. Here, we report that on induction of micRNAs directed against the coat protein and/or the replicase of the *E. coli* bacteriophage SP, phage proliferation was effectively prevented. We propose that the micRNA immune system provides an effective means of preventing viral infection as well as the expression of harmful genes in both prokaryotes and eukaryotes.

To design a micRNA immune system against phage infection in *E. coli*, we chose coliphage SP, a positive, single-stranded RNA, F-specific phage, which was isolated in Japan and classified in the group IV coliphages[10]. The entire phage genome consists of ~4.2 kilobases (kb) and its complementary DNA has been cloned (pSP219; Y.I. and A.H., in preparation). The nucleotide sequence of the entire genome reveals that the RNA phage codes for a maturation enzyme, coat protein, coat readthrough protein and replicase (see Fig. 1*a*) (Y.I. and A.H., in preparation).

Previous work has shown that micRNAs that are able to hybridize with the target mRNA over the region containing the Shine–Dalgarno sequence and the initiation codon are the most effective repressors of gene expression[7]. Therefore, fragments A and B in Fig. 1 were used to construct the micRNA immune system: fragment A consists of the 247-base-pair (bp) *Cla*I/*Aha*III fragment encompassing the Shine–Dalgarno sequence and the initiation codon of coat protein; fragment B consists of the 159-bp *Rsa*I/*Aat*I fragment encompassing the Shine–Dalgarno sequence and the initiation codon of replicase. In addition to these two fragments, a DNA fragment (fragment C in Fig. 1) from the 3′ end of the phage genome was also used; this fragment was derived from a *Bam*HI/*Pvu*I digestion of pSP219, a cDNA clone constructed from poly(A)-tailed phage RNA. Therefore, fragment C consists of ~690 bp: 411 bp from the C-terminal coding region of the replicase gene, 107 bp from the 3′-noncoding region, ~60 bp from the poly(A) tail, and 111 bp from the vector pBR322 (*Pvu*I–*Sca*I). These DNA fragments were inserted into the unique *Xba*I site of the micRNA cloning vector, pJDC406 (Fig. 1*b*), by blunt-end ligation. Thus, transcription of the inserted DNA is controlled by the strong *lpp* promoter and the *lac* promoter–operator, so that the production of a large amount of RNA transcript can be induced in the presence of a *lac* inducer, such as isopropyl-β-D-thiogalactoside (IPTG)[7]. The orientation of the inserted DNA fragments was determined by restriction site analysis, and those plasmids in which fragments A, B and C were inserted in the anti-sense transcription direction with respect to the *lpp* and *lac* promoters were designated pMIC-A, pMIC-B and pMIC-C, respectively. As clear gene dosage effects have been demonstrated previously[7,11], we also constructed the following plasmids carrying two or three micRNA genes: pMIC-A:A (2 × *micA*, that is, two *micA* genes in one plasmid), pMIC-A:B (*micA* plus *micB*), pMIC-C:C (2 × *micC*) and pMIC-A:B:C (*micA* plus *micB* plus *micC*).

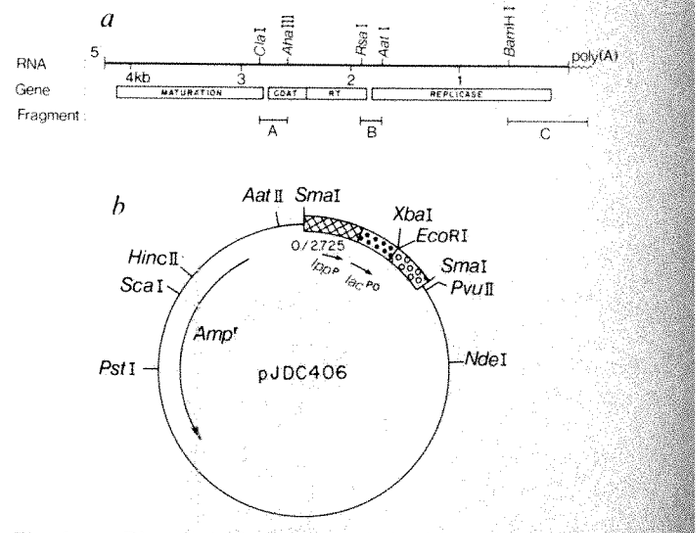

Fig. 1 *a*, Diagrammatic representation of bacteriophage SP. Numbers refer to the distance (in kilobases) from the 3′ terminus. Only the relevant restriction sites are shown. RT, coat readthrough protein. Fragments A, B and C were used to construct the micRNA plasmids pMIC-A, pMIC-B and pMIC-C respectively. *b*, Restriction map of micRNA vector pJDC406. Numbers refer to size in kb. Cross-hatching represents the *lpp* promoter, filled circles represent the *lac*UV5 promoter–operator, and the open circles represent the *lpp* ρ-independent transcription terminator. pJDC406 was constructed from pJDC402 (for description see ref. 7) by deleting 0.3 kb downstream of the *lpp* terminator (including the downstream *Eco*RI site) and changing both *Hin*fI sites flanking the micRNA transcription unit to *Sma*I sites with the use of *Sma*I linkers (CCCGGG). The micRNA plasmids were constructed by inserting the fragment of interest into the unique *Xba*I site after creating flush ends with DNA polymerase I Klenow fragment. To construct pMIC-C:C, the smaller *Sma*I fragment from pMIC-C was inserted into the *Pvu*II site of a second pMIC-C, resulting in two *micC* genes on one plasmid. pMIC-A:B and pMIC-A:A were constructed by inserting the smaller *Sma*I fragment from pMIC-A into the unique *Nde*I site of pMIC-B and pMIC-A, respectively. pMIC-A:B:C was constructed by inserting the smaller *Sma*I fragment from pMIC-C into the unique *Aat*II site of pMIC-A:B.

Figure 2*a* shows growth curves of *E. coli* JA221/F′LacI^q (*hsdR leuB6 lacY thi recA* Δ*trpE5*/F′ *lacI^q lac$^+$ proAB*)[12] carrying the construct pMIC-A:B:C. micRNA production was induced by adding 2 mM IPTG before phage infection. Phage infection was carried out at a multiplicity of infection of ~15. Control cells carrying the vector plasmid alone were lysed after infection whereas cells carrying pMIC-A:B:C did not lyse in the presence of IPTG, although growth stopped after phage infection (Fig. 2*a*). This result indicates that the induction of micRNAs inhibited the proliferation of phage SP. Partial inhibition was observed even without the addition of IPTG, a result of incomplete repression of micRNA gene transcription in pJDC406 (ref. 7). Plaque formation was also inhibited when the cells carrying pMIC-A:B:C were used as indicator bacteria in the presence of IPTG. Figure 3*a* shows plaque formation of phage SP on *E. coli* JA221/F′LacI^q carrying only the vector plasmid (pJDC406) in the absence and presence of IPTG. IPTG has little effect on either the number of plaques or the plaque morphology [Fig.

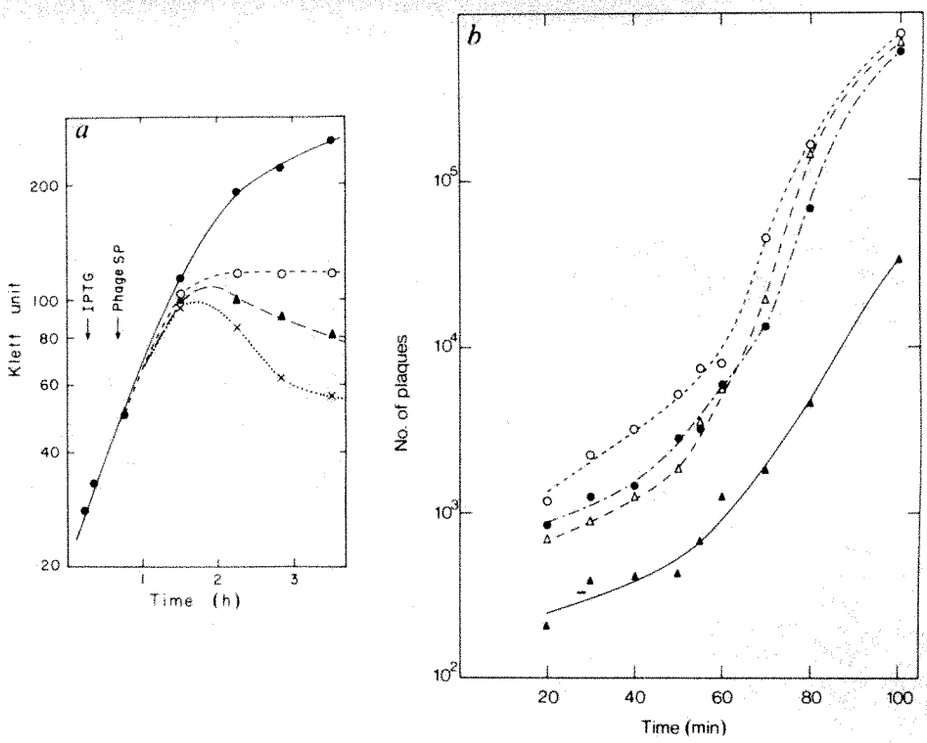

Fig. 2 *a*, Effect of phage SP on the growth curve of *E. coli* JA221/F'LacI^q containing pMIC-A:B:C or pJDC406. Cells were grown in L-broth[13] containing 5 mM $CaCl_2$ in the presence or absence of the *lac* inducer IPTG (2 mM). ●—●, Turbidity of cultures containing pMIC-A:B:C or pJDC406 without phage SP in the presence or absence of IPTG. ×···×, Turbidity of a culture containing pJDC406 plus phage SP in the presence or absence of IPTG. ○---○, Turbidity of a culture containing pMIC-A:B:C in the presence of both IPTG and phage SP. ▲--▲, Density of a culture containing pMIC-A:B:C in the absence of IPTG and in the presence of phage SP. The labelled arrows indicate the times of addition of IPTG (to induce the micRNA genes) and of phage SP. *b*, Phage titre of the cell culture at various times after addition of phage SP. Circles represent *E. coli* JA221/F'LacI^q harbouring pJDC406; triangles represent JA221/F'LacI^q harbouring pMIC-A:B:C. Open symbols represent cultures grown in the absence of the inducer IPTG; solid symbols represent cultures grown in the presence of IPTG (2 mM) for 1 h before phage infection. Cells were grown in L-broth containing 5 mM $CaCl_2$ to a Klett-Summerson reading of 10, at which point IPTG was added to half of each culture. The cultures were grown for a further hour to a Klett reading of 55, at which time phage SP was added at a multiplicity of infection of 0.1. After 10 min the cultures were diluted 10-fold to decrease the changes of re-infection. At each time point, the appropriate dilutions of each culture were immediately mixed with a large excess of a stationary culture of *E. coli* A/λ and plated on to plates of L-broth. Plaques were counted after 12 h of growth. The initial amount of free phage was subtracted from each time point; this number was determined by titering $CHCl_3$-resistant phage in the culture at 20 min. In all cases free phage numbered ~300.

3*a*(−) and (+)]. However, in the same *E. coli* strain carrying pMIC-A:B:C, the number of plaques was drastically decreased to about one-tenth of the control value (Fig. 3*a*) in the presence of IPTG. Note that 10 times more phage were plated out in Fig. 3*b*(+) than on all the others. In addition, the plaques in Fig. 3*b*(−) are much smaller than the control plaques. In the presence of IPTG [Fig. 3*b*(+)], the number of plaques decreased further, and the plaques were very small and difficult to see. These results are consistent with those shown in Fig. 2 and clearly demonstrate that micRNAs targeted against phage genes are able to effectively block formation of plaques and phage proliferation.

Figure 2*b* shows the phage titre of *E. coli* JA221/F'LacI^q carrying pMIC-A:B:C or the micRNA vector pJDC406 at various times after addition of phage SP. In the presence of IPTG, the number of infective centres decreased by about four-fold in cells carrying pMIC-A:B:C. At 100 min, the phage titre of the cells carrying pMIC-A:B:C in the presence of IPTG was ~0.05 of that observed for control cells (Fig. 2*b*). Note that *micA:B:C* had very little inhibitory effect in the absence of IPTG compared with cells containing the micRNA vector (pJDC406) alone. These results indicate that the inhibitory effect of *micA:B:C* is active throughout the phage infection. The poor yield of phage in the cells carrying pMIC-A:B:C in the presence of IPTG is probably a result of both direct inhibition of translation of the phage RNA and degradation of the phage RNA. Target mRNA degradation has been shown previously to occur after induction of micRNA[3,7].

To demonstrate that the initial effect of the micRNA is caused at least partially by the inhibition of phage protein production, *E. coli* JA221/F'LacI^q (containing either pMIC-A:B:C or the control plasmic pJDC406) infected with phage SP was labelled for 10 min with ^{3}H-leucine. (Infection with phage SP was for 15 min at a multiplicity of infection of 5, after 1 h induction of the micRNAs with 2 mM IPTG.) In the presence of *micA:B:C*,

Table 1 Effects of individual and multiple micRNA genes on SP plaque formation

	Absence of IPTG			Presence of IPTG		
Plasmid	Titre*	% Inhibition†	Plaque morphology‡	Titre*	% Inhibition†	Plaque morphology‡
pJDC406	3,650	0	Normal	3,320	0	Normal

pMIC-A:B	1,710	53	Normal	300	91	Small
pMIC-C:C	3,170	13	Normal	1,510	55	Small

* This value is an average of at least two determinations (s.d. < 30%).
† Calculated relative to the values obtained with pJDC406.
‡ Plaque morphologies are shown in Fig. 3: *a*(+) = normal: *b*(−) = small; *b*(+) = very small.

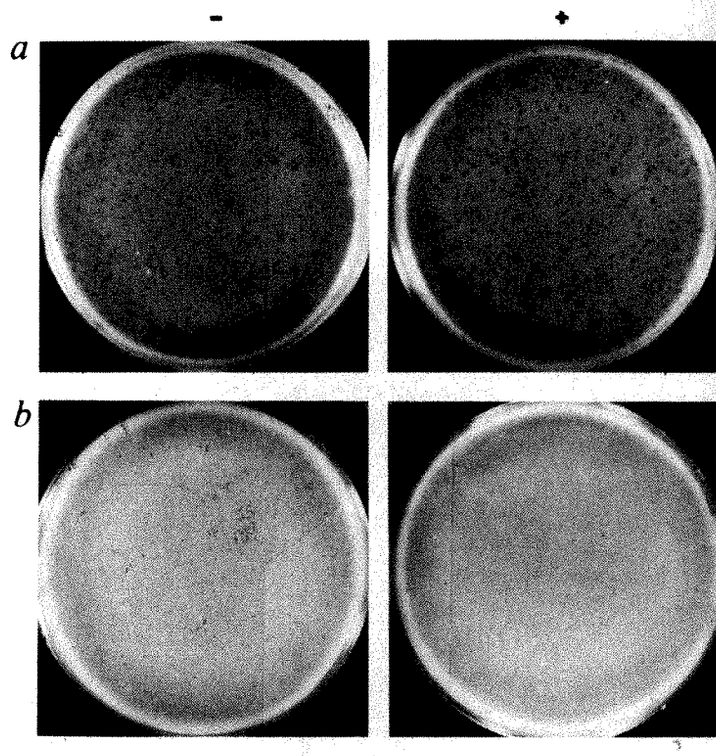

Fig. 3 SP plaque formation on a lawn of *E. coli* JA221/F'LacI^q containing pJDC406 (*a*) or pMIC-A:B:C (*b*) in the absence (−) or presence (+) of the micRNA gene inducer, IPTG. Cultures were grown to late log phase in L-broth[13], at which time IPTG was added (to a final concentration of 2 mM) to half of each culture, and growth continued for an additional 2 h. IPTG was added to the warm L-broth top agar just before plating. Phage and bacteria were mixed 1 min before plating. The concentration of phage plated is the same in each case, except for plate *b*(+) in which 10 times more phage were used.

synthesis of the phage SP coat protein was greatly reduced compared with cells carrying only the micRNA vector pJDC406 (data not shown); other proteins were unaffected.

The inhibitory effects of pMIC-A:B:C were not due to its nonspecific effects on the cells. Cells carrying pMIC-A:B:C are fully sensitive to coliphages Qβ (group III) and GA (group II), which are F-specific, positive, single-stranded RNA phages; the phage GA or Qβ titre remained the same when these phage were plated, with or without IPTG, on *E. coli* JA221/F'LacI^q carrying either pMIC-A:B:C or pJDC406 (data not shown). This result indicates that such cells are fully capable hosts for F-specific phage infection, and that the effects of pMIC-A:B:C are specific to phage SP.

To determine which micRNA genes make the largest contribution to the immunity conferred by pMIC-A:B:C, phage titres were measured for *E. coli* JA221/F'LacI^q carrying the various micRNA plasmids (Table 1). In the case of the single micRNA genes, *micB* and *micA* appear to be more inhibitory to SP in the presence of IPTG than *micC*. Clear gene dosage effects are observed in the presence of two *micA* genes, and when the *micA* gene plus the *micB* gene are present. The *micC* gene in either the single or double configuration also shows inhibition of phage production although to a lesser extent than *micA* or *micB*. It should be noted that the *micC* RNA does not encompass the Shine-Dalgarno sequence or the initiation codon of replicase mRNA. This micRNA may prevent replicase from transcribing the positive RNA strand to produce the negative RNA strand, by forming a hybrid at the 3′ end of the phage RNA.

We have demonstrated that micRNAs effectively block the proliferation of a specific virus. On the basis of our previous findings[7], the micRNAs block the expression of specific SP phage genes by inhibiting the translation of these genes. It is important to note that the micRNA immune system is highly specific; the cells harbouring the micRNA genes directed against phage SP are resistant to phage SP, but not to phage GA or Qβ. In particular, cells were not resistant to phage Qβ despite its extensive homology to phage SP (Y.I. and A.H., in preparation). The high specificity of the micRNA immune system is important for its application in preventing viral infection and the expression of harmful or toxic genes in eukaryotic cells.

Combined with existing technology, the present report provides a promising prospect for the application of the micRNA immune system to both plant and animal cells. It is now feasible to establish transgenic animals carrying a micRNA immune system(s) directed against a specific virus (such as poliovirus or foot-and-mouth disease virus, which are positive, single-stranded RNA viruses), by using micRNA genes that are stably integrated into the desired host genome. Similarly, micRNA immune systems directed against plant viruses can be introduced into the genomes of plant protoplasts which can subsequently be regenerated into mature fertile plants. Also, artificial micRNA repressors have great potential for use in the functional characterization of unknown genes, the repression of harmful genes such as oncogenes, and altered regulation of developmental genes.

We thank Dr A. Jacobson for helpful discussion during this work. The secretarial assistance of Margaret Yazulla and Laura Antonacci is gratefully acknowledged. This work was supported by USPHS grant GM19043.

Note added in proof: Melton[14] has recently shown that complementary RNA injected into frog oocytes will block translation of the specific RNA *in vivo*. In addition, Rosenberg *et al.*[15] have recently shown that when RNA complementary to the *Krüppel* gene is injected into *Drosophila* embryos, a *Krüppel* phenocopy is produced. Furthermore, Izant and Weintraub[16] have demonstrated that a micRNA gene can be inducibly expressed to function in mouse L-cells. Also, Pestha *et al.*[17] have demonstrated in *E. coli* the production of β-galactosidase can be inhibited by the production of a complementary RNA.

High-resolution structure of a DNA helix containing mismatched base pairs

Tom Brown*, Olga Kennard*, Geoff Kneale* & Dov Rabinovich†

* University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, UK
† The Weizmann Institute of Science, Rehovot 76100, Israel

The concept of complementary base pairing, integral to the double-helical structure of DNA, provides an effective and elegant mechanism for the faithful transmission of genetic information[1,2]. Implicit in this model, however, is the potential for incorporating non-complementary base pairs (mismatches) during replication or subsequently, for example, during genetic recombination[3,4]. As such errors are usually damaging to the organism, they are generally detected and repaired. Occasionally, however, the propagation of erroneous copies of the genome confers a selective advantage, leading to genetic variation and evolutionary change. An understanding of the nature of base-pair mismatches at a molecular level, and the effect of incorporation of such errors on the secondary structure of DNA is thus of fundamental importance. We now report the first single-crystal X-ray analysis of a DNA fragment, d(GGGGCTCC), which contains two non-complementary G·T base pairs, and discuss the implications of the results for the *in vivo* recognition of base-pair mismatches.

Two principal schemes have been proposed for hydrogen bonding between non-complementary bases. One of these schemes[2] involves minor tautomeric forms of the bases (Fig. 1*a*, *b*); the resultant base pairs are stereochemically indistinguishable from complementary Watson–Crick base pairs (Fig. 1*c*, *d*). The estimated frequencies of minor tautomers correlate well with the observed frequencies of substitution mutations[5] but there is, to date, no direct structural evidence for such base pairs. In the second scheme[6], both bases are in the major tautomer form, but use different functional groups for hydrogen bonding than Watson–Crick base pairs (Fig. 1*e*, *f*). 'Wobble' base pairs of this type have been observed in various transfer RNA crystal structures[7–11] and in recent nuclear magnetic resonance solution studies of deoxyoligonucleotides[12,13] and polymers[14]. Mis-insertion of bases in their major tautomer form during replication is indicated by kinetic experiments with DNA polymerase I (ref. 15). The energetics of mismatched base pairs have been studied theoretically[16,17].

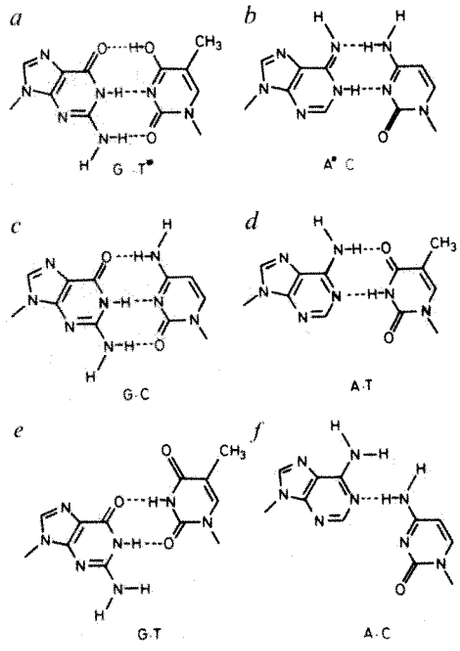

Fig. 1 Schematic diagram of various postulated base-pairing schemes. *a*, *b*, Tautomer pairs; *c*, *d*, Watson–Crick base pairs; *e*, *f*, wobble base pairs. Bases in their rare tautomer (imino/enol) forms are marked by asterisks.

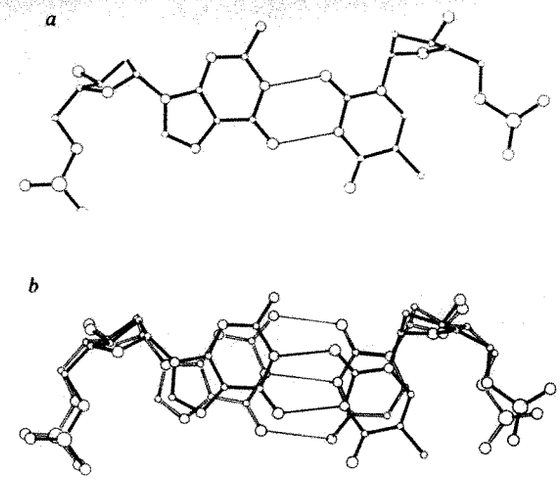

Fig. 2 *a*, The G·T wobble base pair observed in the crystal structure of d(GGGGCTCC). *b*, Superposition of the G·T wobble base pair observed in the crystal structure (dark bonds) on an ideal G·C pair. The figure was constructed by calculating the best molecular fit of the refined structure of d(GGGGCTCC) with a model of d(GGGGCCCC) derived from A-DNA fibre coordinates[24].

Detailed structural information about complementary base pairs is available from single-crystal X-ray diffraction studies of synthetic deoxyoligonucleotides[18–20]. We have now extended this technique to mismatched base pairs by modifying the sequences synthesized so as to include non-complementary bases. The sequence d(GGGGCTCC) is a variant on two other A-DNA type octamers already investigated, d(GGTATACC)[21] and d(GGGGCCCC)[22]. It was prepared by solid-phase triester methods[23] and crystallized from a buffered 3 mM solution of DNA (*p*H 6.5) with 28 mM $MgCl_2$, kept at 4 °C. The hexagonal crystals, space group $P6_1$, $Z = 1$ octamer duplex, had cell dimensions of $a = b = 45.20$ Å, $c = 42.97$ Å, close to those of the parent octamers. Diffractometer measurements at 2 °C yielded 2,414 unique reflections.

A molecular model of d(GGGGCTCC) was constructed, using fibre coordinates for A-DNA[24]. The G and T bases were related as in the minor tautomer pair of Fig. 1*a*. The coordinates of this model, after best molecular fit to d(GGGGCCCC), were the starting point for the refinement by constrained/restrained least-squares techniques. During the refinement no restraints were imposed on either the hydrogen bonding between the G and T bases or the sugar conformation. The present report describes the structure at the convergence of the CORELS[25] refinement at $R = 19.4\%$ for the 1,954 reflections with $F > 2\sigma(F_o)$. Further refinement by the Hendrickson–Konnert[26] technique reduced the R factor to 14.5% and allowed the localization of 56 water molecules, but did not result in any significant changes in the DNA structure. Full details will be reported elsewhere.

During the refinement the largest changes occurred at the positions of the G·T base pairs. The initial 2-fold molecular symmetry was, however, largely retained, as was the geometry of the six G·C base pairs. The bases in the mismatch pairs shifted substantially from their original positions, bringing the keto O-2 and the imino N-3 atoms of thymine within hydrogen-bonding distances of the imino N-1 and keto O-6 atoms of guanine. The refined structure shows unambiguously that both

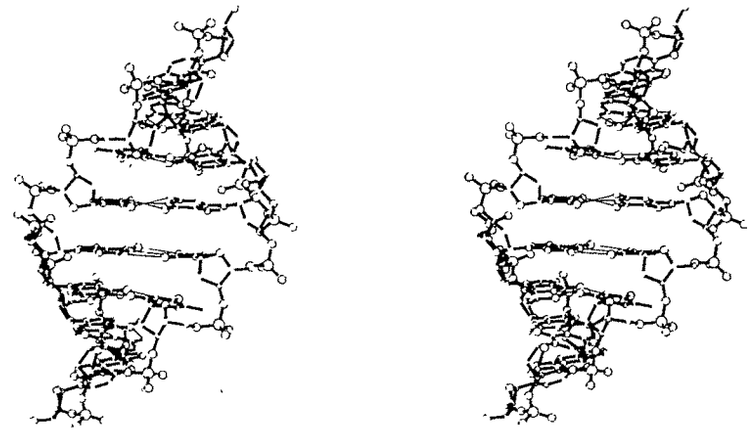

Fig. 3 Stereoscopic view of d(GGGGCTCC) looking into the minor groove. The G·T wobble pairs lie on either side of the two central G C pairs

mismatches are of the wobble type with the bases in the major tautomeric forms (Fig. 2*a*), and gives the first view of a base-pair mismatch in the crystal structure of a DNA fragment. The geometry of the hydrogen bonds linking the bases is good with N···O distances of 2.81 Å and 2.85 Å in the first, and 2.50 Å and 2.66 Å in the second wobble pair.

Comparison of the G·T wobble pair with a Watson-Crick G·C base pair (Fig. 2*b*) indicates that the mismatch can be accommodated in the double helix without appreciable perturbation of the backbone. The sugar conformation remains C-3′ *endo*. The C-1—C-1′ distance is 10.2 Å, close to that observed in G·C pairs.

The greater part of the lateral displacement of the bases is the movement of the thymine into the major groove with root mean square (r.m.s.) displacements of 0.74 Å (for G) and 1.25 Å (for T) (Fig. 2*b*). As a result, the angles between the glycosidic bonds and the C-1′—C-1′ vector, which are symmetrical in Watson-Crick pairs (54-58°)[27], assume values of 70° for T and 41° for G averaged over the two G·T pairs. The free keto O-4 atom of thymine now protrudes into the major groove and the N-2 amino group of guanine into the minor groove; these are available for hydrogen bonding to either solvent molecules or neighbouring double helices. The presence of the two G·T base pairs does not appreciably affect the overall conformation of the A-DNA helix (Fig. 3). The average helical parameters and torsion angles (Table 1) compare well with the corresponding values for the two isomorphous structures. The packing of the duplexes in the crystal structure is similar to that in other A-type structures[18].

Stacking interactions between adjacent base pairs have a major influence on the conformational stability of double-stranded DNA, and have been shown to give rise to sequence-dependent conformational effects[28,29]. Figure 4 compares the base-stacking overlaps in d(GGGGCTCC) with the equivalent steps of A-DNA from fibre data. The most striking change is the improvement of the stacking at the wobble pairs on the 5′ side of the thymine as a consequence of its displacement into the major groove (Fig. 4*c*). On the 3′ side of the thymine there is virtually no overlap between the pyrimidines (Fig. 4*b*). This trend has also been observed for G·U base pairs in tRNA[11]. The stacking of the purines on either side of the mismatch appears to be unaffected.

The structural results derived from the present investigation may have implications for the fidelity of replication and the enzymatic recognition of DNA containing a base pair mismatch. These results can be considered at four levels: the tautomeric form of the bases; local effects, such as base stacking in the neighbourhood of the mismatch; the influence of the base mispairing on the global conformation of the double helix; and the disposition of structural elements, particularly hydrogen donors and acceptors, in a mismatched base pair.

Fidelity of replication is maintained by an elaborate and as yet only partially understood mechanism involving specificity of base selection at the insertion step, proofreading (excision of incorrect bases) and post-replicative mismatch repair[30]. Biochemical experiments show that non-complementary bases in their major tautomer forms can be incorporated during replication. Fersht and co-workers have found this to be the case for purine-pyrimidine mismatches by kinetic analysis of DNA polymerase I mis-insertion rates[15]. The wobble base pair found in the crystal structure examined here may be a good model for G·T mis-insertions.

There is good evidence that mis-insertion frequencies *in vitro* are dependent on the DNA sequence and that this may be a consequence of base stacking effects at the site of the mismatch[31]. The present investigation, based as it is on experimental data from a specific sequence, gives precise information about local changes in base stacking; it shows in particular an improvement in pyrimidine-pyrimidine stacking on the 5′ side of the thymine base of the G·T wobble pair.

Table 1 Overall helical parameters and mean torsional angles for A-DNA structures

	d(GGGGCTCC)	d(GGGGCCCC)	d(GGTATACC)	Fibre model
Twist per b p.	33 4°	31.6°	32.3°	32 7°
Base pairs per turn	10.8	11 4	11.1	11.0
Rise per b.p (Å)	3 0	2.9	2.9	2 6
Base tilt	11°	13°	15°	19°
Propeller twist	15°	10°	13°	Variable
α	−81	−76	−62	−50
β	177	178	173	172
γ	65	62	52	41
δ	76	84	88	79
ε	−136	−156	−152	−146
ζ	−68	−70	−78	−78
χ	−163	−158	−160	−154

Helical parameters are as defined by Fratini *et al*[41]. bp, Base pair The glycosidic torsion angle is defined by the atoms O-1′—C-1′—N-1′—C-2 (pyrimidine)or O-1′—C-1′—N-9—C-4 (purine). Backbone torsional angles are defined by $P\overset{\alpha}{-}O\text{-}5'\overset{\beta}{-}C\text{-}5'\overset{\gamma}{-}C\text{-}4'\overset{\delta}{-}C\text{-}3'\overset{\varepsilon}{-}O\text{-}3'\overset{\zeta}{-}P$

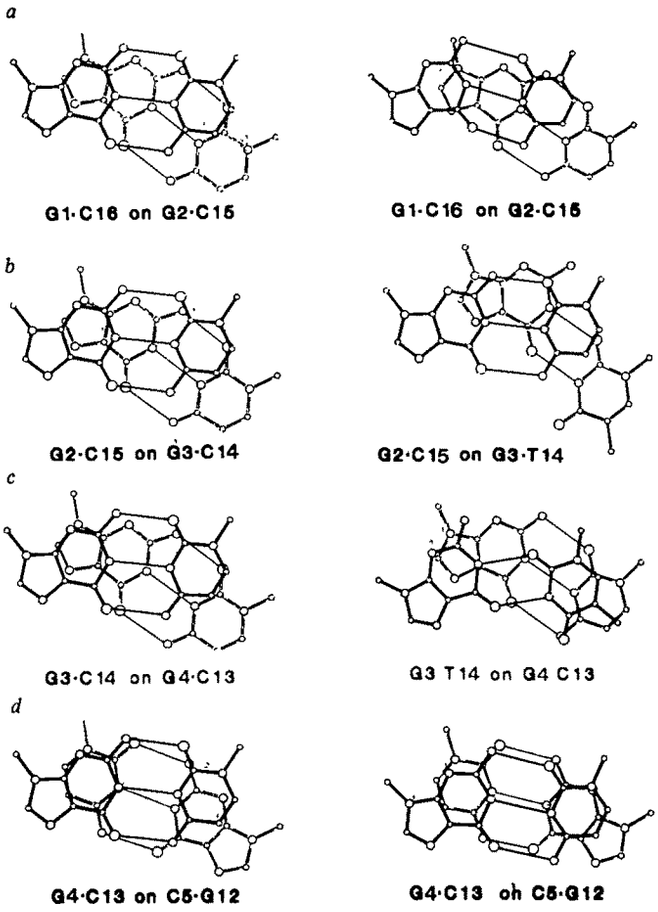

Fig. 4 Projected view of four steps of d(GGGGCTCC) (right) compared with equivalent steps derived from the A-DNA fibre model of poly(dG)·poly(dC) (left). The view is perpendicular to the mean plane through the upper base pairs and is in the 5′ to 3′ direction of strand (G-1-G-4) The upper and lower base pairs are differentiated by dark and light bonds, respectively. Only one half of the octamer is illustrated as the pattern of base stacking is symmetrical about the pseudo 2-fold axis. Note the similarity of the base stacking in the structures at the end step (*a*) and the centre step (*d*). At the site of the mismatch, the stacking of T on C is improved compared with C on C in the fibre (*c*) but the stacking of C on T (*b*) is unaffected.

Once the G·T wobble pair is incorporated in the double helix, it causes little perturbation to the global conformation. Nevertheless, it is discriminated against at various stages both during and after replication. The role of DNA polymerase in the recognition of incorrect base pairs is indicated by the variation of *in vitro* mutation frequencies with the nature of the polymerase[32–35].

DNA polymerase is thought to have only one active site for synthesis, which is able to accommodate all four Watson-Crick base pairs[36]. These base pairs have, as a characteristic structural feature, a pseudo 2-fold axis in the plane of the base pair perpendicular to the C-1′—C-1′ vector, resulting in symmetrical disposition of the glycosidic bonds (Fig. 1*c*, *d*). As a consequence of this symmetry, the positions of the N-3 of guanine, the O-2 of cytosine, the N-3 of adenine, and the O-2 of thymine are approximately equivalent. These atoms are all potential hydrogen acceptors.

The X-ray analysis shows that G·T wobble base pairs in d(GGGGCTCC) lack diad symmetry. The guanine N-3 and thymine O-2 atoms are displaced from their positions in standard Watson-Crick base pairs and are no longer equivalent. The location of these functional groups may be an important factor in enzymatic recognition. The positions of other atoms in the G·T wobble pair also change. The movement of the O-4 and the 5-methyl groups of thymine into the major groove may result in steric hindrance at the active site. Despite these differences, some major tautomer mismatches escape detection during *in vitro* DNA replication, possibly because of the lack of base specificity of DNA polymerase. However, at the post-replicative stage there may be a more specific recognition system with separate enzymes or active sites for the different mismatched pairs[37].

The present investigation gives high-resolution structural information about a G·T mismatch in a DNA sequence which crystallizes as an A-type helix. There is a need to examine base pair mismatches in all known DNA helices as there is accumulating evidence for conformational flexibility of *in vivo* stretches of DNA[38–41]. We have recently solved, and are currently refining, other crystal structures and find that the G·T wobble pair, with the same hydrogen-bonding pattern, also occurs in a Z-DNA fragment d(TGCGCG) ($R = 24\%$), in a B-DNA dodecamer d(CGCGAATTTGCG ($R = 23\%$), and in another A-type octamer, d(GGGGTCCC) ($R = 15\%$). The results of these studies will be reported elsewhere. Our current investigations establish the feasibility of introducing errors into DNA sequences known to crystallize as A, B or Z helices, opening up the possibility of studying a variety of base pair mismatches and modified bases in different environments. This approach may lead to a better understanding, at the molecular level, of departures from complementary base pairing in the double helix.

O.K is an External Staff Member of MRC and the work was supported by a MRC programme grant. We thank MRC and EMBO for a Visting Fellowship (to D.R.), our colleagues W.B.T. Cruse, M. McCall, S. Salisbury and M. A. Viswamitra for helpful discussions, and Professor R. A. Raphael for his advice and unfailing support. We thank our colleague Dr W. Hunter who carried out the Hendrickson–Konnert refinement.

Computer Methods and Programs in Biomedicine covers computing methodology and software systems, derived from computing science for implementation in all aspects of life science research and medical practice.

The aims of **Computer Methods and Programs in Biomedicine** are: (1) to encourage the development of formal computing methods, and their application in life science research and medical practice, by illustration of fundamental principles in biomedical informatics research; (2) to stimulate basic research into application software design; (3) to report the state of research of biomedical information processing projects; (4) to report new computer methodologies applied in biomedical areas; (5) the eventual distribution of demonstrable software to avoid duplication of effort; (6) to provide a forum for discussion and improvement of existing software; (7) to optimise contact between national organisations and regional user groups by promoting an international exchange of information on formal methods, standards and software in biomedicine.

J. G. LLAURADO, *Loma Linda, CA 92357, U.S.A.*

The International Journal of Bio-Medical Computing provides an international forum for the presentation of original work, interpretative reviews and discussion of fundamental research and new developments in the application of various types of computers (digital, analogue and hybrid) to instrumentation in medicine and the life sciences in general.
In addition to original research papers and reviews, a Commentary section provides short digests on recent developments in clinical applications of computing.

BIOPHYSICS, BIOENGINEERING AND MEDICAL INSTRUMENTATION

Excerpta Medica Section 27

This abstract journal starts with general chapters on the basic concepts of biophysics and bio-engineering, instrumentation (amplifiers, generators, recorders, cameras) and computers. The main body of information is organized into chapters for specific measurements (temperature, time, frequency, pressure, flow, electrical phenomena, hydrogen ion concentration, radiation etc.), surgical instruments and the specialised instrumentation required in 19 different areas of biomedical science (the study of metabolism, the various organ systems of the body, radiology, anesthesia, monitoring). At the end of each issue there is also a special chapter on computer applications in medicine, including hospital administration, diagnosis, patient monitoring, function tests and the documentation of the biomedical literature.

ACADEMIC PRESS

COMPUTER SCIENCE JOURNALS

Journal of Symbolic Computation

NEW!

Editor Bruno Buchberger

Johannes-Kepler-Universitat, Institut fur Mathematik, A-4040 Linz, Austria

The explicit goal of the Journal is to promote the integration of the field of symbolic computation by establishing one common forum for researchers working in the different subareas. It is important that the algorithmic achievements of these areas should be made available to the human problem solver in integrated software systems for symbolic computation. To help this integration the Journal will publish invited tutorial surveys on subareas of symbolic computation. Similarly, as symbolic software systems become essential for working scientists in chemistry, physics, etc., the Applications Letters Section is designed to present recent information on successful applications of such systems.

Volume 1, 1985, 4 issues.
UK: £60.00. Overseas: $95.00.

Journal of Parallel and Distributed Computing

Editors-in-Chief
Kai Hwang and Leonard Uhr

This international journal is directed to researchers, engineers, educators, managers, programmers, and users of computers who have particular interests in parallel processing and/or distributed computing. The goal of the Journal is to publish original research papers and timely review articles on the theory, design, evaluation, and practices of parallel and/or distributed computing systems.

The Journal intends to provide an effective forum for communication among researchers from various scientific areas working in a wide variety of problem areas, sharing a fundamental common interest in improving the ability of computers to solve increasing numbers of difficult and complex problems as quickly and as efficiently as possible.

Volume 2, 1985, 4 issues.
UK: £59.50. Overseas $83.00

International Journal of Man-Machine Studies

Executive Editors
B. R. Gaines and D. R. Hill

A broadly based cross-disciplinary journal covering all aspects of person-computer interaction, the **International Journal of Man-Machine Studies** was founded as a quarterly in 1969, and has played a leading role in establishing the field of human-computer studies. Now the major journal in this field it pioneered in publishing work on speech communications with computers, programming language psychology, applications of fuzzy set theory, dialogue engineering and many other areas that have become major foci for work on human-computer systems.

Computer scientists read it for the psychology papers, psychologists for the computing papers, industrial and other applied scientists, for its broad coverage and applications orientation.

Volumes 22, 23, 1985, 12 issues.
UK: £140.00. Overseas: $337.00.

Journal of Microcomputer Applications

Editors-in-Chief
J. L. Alty and M. J. Taylor

The **Journal of Microcomputer Applications** is primarily concerned with the applied areas of microcomputers and microtechnology in academic and industrial environments. Rapid publication is a key aspect of this journal since it is important that papers in this fast moving field are published quickly.

The readership of this journal will comprise all those who are actively engaged in the design, production and testing of microcomputer systems and their applications. A technical background will therefore be assumed. The journal should thus be of great value to those familiar with the technical aspects of microcomputer systems bringing to their attention novel and interesting solutions.

Volume 8, 1985, 4 issues.
UK: £42.00. Overseas: $98.50

The future lies ahead

Gunther S. Stent

Solid Clues: Quantum Physics, Molecular Biology, and the Future of Science.
By Gerald Feinberg.
Simon & Schuster: 1985. Pp.287. $17.95. To be published in Britain later this year by Heinemann.

IN THE Introduction to *Solid Clues*, Gerald Feinberg observes that 40 years ago no one predicted the enormous expansion of science then imminent. This unpredicted expansion included also the rise of "futurology", the very discipline dedicated to correcting our generally myopic view of the future. In contrast to old-time, apocalyptic or millennarian prophecy, which foretold the future on the basis of inspired visions in terms of value-laden, prescriptive proclamations, the predictions of futurology are phrased as rational arguments, based on some theory of the dynamics of history, and take the form of value-free and descriptive propositions.

Feinberg's avowed purpose is to predict the changes that will take place over the next few decades in the content of science and the lives of scientists. He concentrates his attention on physics and biology, the two branches of contemporary science which he finds to be progressing most rapidly and likely to produce the most important discoveries. Fortunately, as a professor of physics at Columbia University and having read some books and articles on contemporary biology, Feinberg is able to assess the present status of these two vanguard disciplines. Unfortunately, he seems to lack the grounding in the philosophies of science and history needed by the would-be futurologist, as well as an appreciation of what counts as a rational argument in the social sciences (rather than a mere assertion) and as a significant prediction (rather than a futurological platitude).

Feinberg will surprise few readers with his disclosure that one of "the main engines of change in science, the forces that act to change science from within and from the outside" is the development and application of new experimental, observational and mathematical techniques. Equally unsurprising is his revelation of the public attitude to science, reflected by the provision (or withholding) of financial support and the encouragement (or proscription) of certain topics of research, as another such main engine (or brake). So, how, being driven by these engines, is science going to advance in the future? Well, it will answer some old questions and discard others, with some of the answers to old questions in turn raising new questions. Is science going to progress indefinitely? Yes and no: "in some areas of science, new answers may bring us close to exhausting fundamental discoveries in the field . . . [whereas] other fields, such as cosmology, are more open-ended". Feinberg lists some of the currently unsolved problems of cosmology and suggests novel observational techniques whose development would open up entirely new cosmological vistas. But he does not present any explicit argument which shows why cosmology is open-ended.

For the future of biology, Feinberg seems safe in predicting that its "main work is to find answers to many of the open questions about living things". He believes that the origin of life, metazoan development — from zygote to cadaver — and the nervous system loom large among such questions. He predicts, moreover, that the incipient development of X-ray laser holography will advance the frontiers of biology as far as did the invention of the optical microscope in the seventeenth century. Whether there are any open-ended areas of biology, however, Feinberg does not say, nor does he trouble to justify his rather doubtful prediction that "biology will become more like the physical sciences, reasoning from general principles to specific cases".

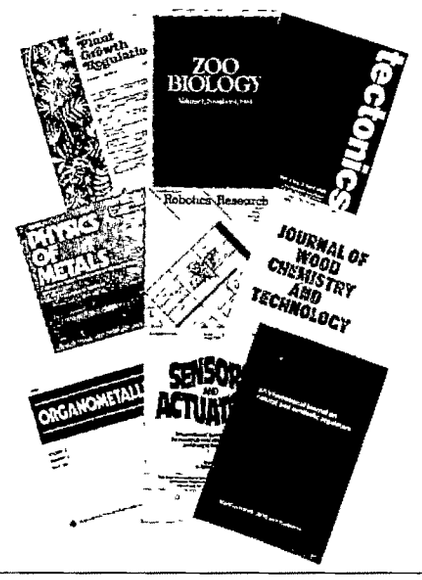
Feinberg thinks that "of all the changes that have taken place in recent years in how science is done, none is more fundamental and sweeping than the use of computers . . . computers are now launching science into a new age". This phenomenon is attributable not merely to the capacity of computers to manage vast amounts of data, such as those which accumulate in particle physics experiments carried out in high-energy accelerators or in molecular biological analyses of DNA and protein sequences. No, we are on our way to a new age because "one of the most intriguing possibilities is that computers will someday be developed that equal or even surpass human capabilities for creating new scientific ideas". Feinberg cites Herbert Simon's "Bacon" program of scientific induction as a first stage on the trip to the new age, apparently unaware that the inductive Baconian model of scientific discovery failed, not because, as he claims, "there was no straightforward method of finding pattern in the data", but because of the need to make an intuitive preselection of the kind of data in which a significant pattern is to be sought in the first place. (In the case of Simon's program, the computer is provided with such preselected data as paired values of force and acceleration and, finding that they vary in direct proportion, the computer "discovers" Newton's Law.) The well-known epistemological critique of claims on behalf of creatively "intelligent" machines notwithstanding, Feinberg imagines "a future in which in the early training of a scientist the computer will act as a teacher, and later as a research collaborator".

What about technological advances? Feinberg points to "nanoengineering", or direct physical manipulation of molecules or atoms, which will allow "the construction of objects of a previously unimagined complexity" and the production of novel materials whose strength exceeds that of presently available materials by factors of many thousands. And then there is, of course, the new "biotechnology", including genetic engineering, for which Feinberg is not alone in anticipating profound effects on the human condition, especially in so far as modifying the natural process of ageing is concerned.

Feinberg concludes his essay with a

New journals review

On 26 September *Nature* will publish the fifth annual review supplement devoted to science journals.



Criteria for inclusion of a journal in the 1985 issue are that:

(i) the first number appeared, or the journal was retitled, *between June 1983 and May 1984* (the second cut-off date allows at least three issues of a journal to have been published, the minimum number on which a reasonable judgement can be based);

(ii) it is published at least three times a year;

(iii) the main language used is English.

Publishers and learned societies are invited to send *four different issues of each suitable periodical, including the first and most recent numbers* (if from outside the United Kingdom, by air mail) to: The Review Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF, England. Subscription details for both 1985 and 1986 should be included.

discussion of two philosophical issues. One is the place of science in the world; here, more prophet than futurologist, Feinberg strikes a righteous pose. He offers dogmatic pronouncements about a wide range of religious, ethical, political and sociological topics, which reflect mainly the unsophisticated views of the typical scientist-in-the-street. The other issue concerns the change in the nature of scientific explanation and the possible limits to understanding. Thanks to his professional background in modern physics, Feinberg has a much better grasp of this matter. He shows how the rise of the quantum theory has eroded some of the basic conceptual ingredients of explanation — foremost among them cause and effect. Moreover, many of the unsolved problems in both physics and biology pertain to highly complex systems in which tiny fluctuations in one variable have huge effects on other variables. The "chaotic" behaviour of such systems limits the degree to which we can hope to fathom them. Thus, as Feinberg points out to his regret, "future science may see more restrictions on what we are able to understand and predict". Also, because of "the immense expansion of scientific information . . . scientists can learn an ever smaller part of what is known and can concern themselves with an ever narrower segment of it . . . . Science is thus in some danger of losing its character as a cumulative body of knowledge". Despite his regret over these limits, Feinberg ends on an upbeat note, befitting his smiling, *simpatico* portrait shown on the dust jacket: "Present and future discoveries in science can transform human life. All of these represent bright prospects of future science".

It may be mean to cavil at this well-meaning essay by a scientist whose interests and concerns clearly transcend his research specialization. But, all the same, it would be negligent for a reviewer not to point out that, just as in the "hard" natural sciences, there are also professional standards in the "soft" social sciences, and that, just as in particle physics, in futurology triviality is even more grievous than error. □

Gunther S. Stent is Professor of Molecular Biology at the University of California, Berkeley.

At the interface

D.H. Everett

Adsorption and the Gibbs Surface Excess.
By D. K. Chattoraj and K. S. Birdi.
Plenum: 1985. Pp.471.
$71.40, £56.53.

IN THIS book Chattoraj and Birdi have set out to demonstrate the central role played by the Gibbs surface excess in describing adsorption phenomena in systems involving liquid–vapour, liquid–liquid, solid–vapour and solid–liquid interfaces, and in biological structures. This attempt to present a unified approach to a wide range of phenomena is to be welcomed. Unfortunately, the treatment leaves much to be desired.

The arguments employed often lack the rigour and self-consistency essential in discussions of thermodynamics. Thus, in the introductory chapter, the surface tension is introduced simply as "surface energy", while in considering the equilibrium between bulk and surface phases the role of surface tension is ignored. Later, in Chapters 3 and 5, correct derivations of the equilibrium condition are given and the surface tension term is now included. In the earlier treatment the surface tension term is apparently hidden in the surface activity coefficient, as perhaps implied in the unhelpful comment that "the standard scale for the surface activity coefficient is uncertain". Elsewhere different definitions of surface activity coefficients are introduced: that they are different quantities is suggested by the comment that one must "use the appropriate reference scale". Which? Also puzzling is this statement:

> In the derivation of the Gibbs adsorption equation the contribution of the β-phase to the interfacial phase is implicitly neglected. The surface activity coefficients thus evaluated *in all probability* [my italics] include this contribution.

Words such as "in all probability" are unacceptable in a thermodynamic argument.

Description of the Gibbs method is, surprisingly, deferred until Chapter 3: it should have been in Chapter 1. The formal definition is correct, but its status is obscured by the comment that "this approach is extrathermodynamic but no mathematical error is involved in the postulate". There is nothing extra-thermodynamic in Gibbs's treatment: what it does is to provide a means of quantifying the macroscopic stoichiometric effect of the inhomogeneous distribution of matter in the interface. At no stage did Gibbs "imagine" that the "moles of solvent present in the interfacial region is zero". His definition is independent of any molecular model, a feature which gives it its power, usefulness and wide applicability.

The book is illustrated by a substantial body of experimental material drawn from a variety of systems, much of it originating from the authors' laboratories. Overall, one has considerable sympathy with Chattoraj and Birdi's objectives, which are to some extent achieved. But it is unfortunate that to get the best out of the book the reader has to be constantly on the alert to avoid being misled. □

D H. Everett is Emeritus Professor of Physical Chemistry at the University of Bristol.

Breeding resources

A.D. Bradshaw

Crop Genetic Resources: Conservation and Evaluation.
Edited by J.H.W. Holden and J.T. Williams.
George Allen & Unwin: 1984. Pp.296. Hbk £25, $40; pbk £9.95, $14.95.

THE key to this book is on p.212. In a well-documented review amongst a group of similar papers, J.R. Harlan assesses the value of wild relatives of crop plants in modern plant breeding. If anybody thought that we could do without all this wild material, here is the corrective — a sober account of the improvements in ecological tolerance, disease and pest resistance, quality, yield and even modes of reproduction which have come from relatives of present crop plants. But at the same time Harlan illustrates the consequent dilemma: because this potentially valuable material is scattered through innumerable species around the world, it is almost impossible to know where the next important source will be.

This is of course only half the story. The enormous losses of natural and semi-natural environments and the increasingly widespread use of new crop varieties mean that this wealth of genetic material is rapidly being depleted. Landmarks in the growth of concern were two FAO/IBP conferences (1968 and 1973) on the conservation of crop genetic resources. Also in 1973, the International Board for Plant Genetic Resources was formed to bring some international organization into the many efforts which were then starting, including the international network of regional centres for crop research and genetic conservation.

Ten years have now passed. In the book there are 24 papers reviewing the progress that has been made, each written by people who are eminent in their field. It is their undoubted experience which leaves a feeling of great unease about the magnitude of the task ahead.

It is easy to define some of the difficulties. In the first part of the book, on seed storage, Roberts and Ellis show elegantly the progress that has been made in quantifying deterioration by predictive equations, and Hanson how we are becoming able to store even some recalcitrant seeds. Ellis and Roberts discuss programmes for monitoring deterioration, advocating important new systems of sequential probability ratio tests. But while the International Rice Research Institute had 25,600 accessions in 1974, it now has more than 50,000. Despite improvements, the problem remains enormous.

The second group of papers deals with the capture and retention of variability. Gale and Lawrence consider how to overcome the problems of the decay of variability in conserved material, while

Chapman discusses the size of seed banks. This should be a crucial paper but few people will be convinced that the problem can be resolved on the basis that the variability in which plant breeders are interested is distributed at random; indeed several of the other contributions indicate that it is not, particularly because of the local origin of variation and the impact of local selection. The assessment by Singh and Williams is much more pragmatic.

Progress in *in vitro* preservation is covered by Withers; the problems of preservation of wild species *in situ* by various forms of nature reserves are assessed judiciously by Ingram and Williams; and there is a series of excellent papers on the evaluation of what has been collected. Apart from Harlan's review, we are left with the overwhelming picture that we can conserve anything if we have the money, but that we are drowning in the twin problems of what to conserve and, once we have conserved it, how to use it. Papers on the fashionable new technique of some clonal variation and recombinant DNA suggest that this is where the future lies. I doubt it.

In his final paper, Holden argues that orthodoxy allied to critical commonsense is the real way forward. We shall need further collections, but now they must be only of threatened material and to cover particular deficiencies, and must be on an international basis: a very sensible end to a valuable and provocative book. □

A.D. Bradshaw is Holbrook Gaskell Professor of Botany at the University of Liverpool.

Mixed selection

Richard G. Klein

Hominid Evolution and Community Ecology: Prehistoric Human Adaptation in Biological Perspective.
Edited by Robert Foley.
Academic: 1984. Pp.296. $37.50, £24.

WHILE the layman may be fascinated simply by the great age of ancient bones and artefacts, palaeoanthropologists value them mainly as data by which to follow the course of human biological and cultural evolution. Such objects are often ambiguous in their implications, and using them to construct a truly compelling and comprehensive story remains a difficult task. In large part, the problem is the actual quantity and quality of bones, artefacts and other real data, which are often distressingly sparse. In part, it is also a matter of the need for more powerful analytical frameworks, based largely on present processes that must also have operated in the past.

One framework that nearly all palaeoanthropologists use, at least implicitly, centres on the concept of natural selection and its ramifications, that is evolutionary theory. Robert Foley, the editor of this book, believes that palaeoanthropologists should apply evolutionary theory more explicitly, especially the idea of coevolution, according to which members of an ecological community evolve at least partly in response to evolutionary changes in other members. Thus, for example, as predators become fleeter of foot, natural selection will tend to favour fleeter prey, and fleeter prey will in turn lead to selection for fleeter predators.

To explore the implications of ecological thinking for palaeoanthropology, in 1981 Foley organized a symposium from which the present book grew. Six of the contributors attended the symposium and four did not, but each was asked to write a chapter illustrating the role of ecological concepts in understanding human evolution. Perhaps not surprisingly, Foley's own contributions come closest to the mark. In the first of his two chapters, he succinctly outlines those aspects of evolutionary theory he thinks palaeoanthropologists will find most pertinent. In the second he discusses the variables — mode of locomotion, body size, population density, home range size, group size, diet, social organization, environment and so forth — that are clearly crucial for reconstructing the ecology of very early people. Unfortunately, most of the variables are very poorly controlled with real data, and Foley's ecological reconstruction is necessarily vague and inconclusive.

Among the other authors, perhaps the one who took Foley's brief most seriously was Garrard, who suggests that the extinction of some Pleistocene mammals in south-west Asia may have been caused by "human interspecific competition", by which he means competition between people and animals for the same resources. This is an interesting possibility, but Garrard presents no real supporting evidence, and his treatment of the broader issue of extinctions is very weak, despite its obvious relevance to the book's main purpose.

Two other contributors who deal reasonably closely with Foley's stated theme are Turner and Gamble. In an essay that is stimulating and thoughtful, but ultimately unconvincing, Turner argues that the Middle and Upper Pleistocene dispersal of human beings across Eurasia and into the Americas can be illuminated by an analysis of the dispersal of other large mammals, especially predators. In a stylistically similar essay dominated by highly readable argumentation rather than empirical demonstration, Gamble suggests that differences in available energy can be used to explain regional variation in the Palaeolithic archaeological record of Europe.

Some of the remaining chapters are closer to the book's theme than others, but none deal with it directly. Potts concludes that early people probably accumulated most of the bones at some sites in Olduvai Bed I, though the sites need not have been "home bases" in the sense of modern hunter-gatherer camp sites. To support his conclusion, Potts cites the presence of numerous stone artefacts, as well as features of the bone assemblages that are probably due to people rather than to carnivores or other "natural" agencies.

Scott deals clearly and succinctly with the evidence for human occupation of Britain in the second half of the Last Glacial period. Conditions were obviously extremely harsh and, compared to the situation in many parts of western Europe, people appear to have been rare. Hill touches on the question of how we might distinguish bone accumulations created by hyenas from those created by people, but he focuses mainly on the scientific-philosophical nature of explanation or interpretation in palaeoanthropology. Although it might not have been Hill's intention, it could be concluded that he believes the interpretation of Plio-Pleistocene bone assemblages is something we can write about but not actually do.

Gowlett sees stone artefacts, humanly butchered animal bones and other archaeological traces as reflections of the existence of human mental abilities from at least two million years ago. He may also believe that natural selection sponsored progressive change through time in these abilities, but from his presentation one cannot be sure.

Finally, Roberts provides a clear, up-to-date and comprehensive overview of Pleistocene climatic change, particularly as it is known from deep-sea cores, and Stringer surveys the human fossil record, stressing broad issues such as the mode of human evolution (whether gradual or punctuated) and the possible importance of climate as a selective factor on body form in fossil people. As independent contributions in their respective fields, Roberts's and Stringer's chapters are among the best in the book, but they are also among the furthest from the central theme.

Sadly the book does not demonstrate the value of specific ecological concepts for understanding human evolution, if only because most of the authors fail to address the issue directly. Beyond lacking a common focus, the chapters also vary considerably in quality, and I think it can reasonably be asked whether they should have been published together. There is a great deal in the book to interest any palaeoanthropologist, but there is also much that would have been winnowed out or improved if the papers had been subjected to the refereeing process used by most specialist journals. □

Richard G. Klein is a Professor in the Department of Anthropology at the University of Chicago.

Recipes for success in the laboratory

Richard Perham

Methods in Molecular Biology, Vols 1 and 2.
Edited by John M. Walker.
Humana/Wiley: 1984/1985. Each volume pp.370, $45, £41.

A CYNICAL older colleague once advised me that any successful academic would turn out to be one-armed, for only then would he be prevented from saying "On the one hand, this; on the other hand, that". By the same token, the author of a book on methods is confronted with a comparable problem; do I tell my readers about all the different ways to carry out this or that technique or do I limit myself to one which, from personal experience, I know works? Any practising molecular biologist will be aware that the same experimental technique is often carried out differently in different laboratories. The differences may be major, they may be minor: in some instances they will actually matter.

The contributors to these two volumes have, for the most part, opted for the second course. Each method selected for description receives an account replete with experimental detail, taken presumably from the author's laboratory notebooks. There are few caveats, even fewer descriptions of variations or alternatives. There are, of course, further references given for those interested in pursuing them and sometimes a range of useful hints on trouble-shooting. Volume 1 deals with proteins, Vol. 2 with nucleic acids. I cannot speak with authority on every method listed — the net has been cast very wide — but I could find no serious fault with the recipes for those methods I know well.

I do have some reservations. For example, Vol. 1 has 38 chapters covering techniques from the Lowry method of protein estimation to manual microsequencing, from polyacrylamide gel electrophoresis to hybridoma production. Some room might have been found for the chemical modification of proteins and the methods, enzymic and chemical, of peptide bond cleavage. Even something as basic as the *S*-carboxymethylation of proteins is tucked away in a description of peptide separation by hplc. On the other hand, automated sequencing is wisely eschewed, given the requirement for unusually sophisticated and expensive apparatus.

The second volume is, if anything, more comprehensive, the 53 chapters starting with DNA assay and isolation and ending with DNA sequencing. In between it covers mRNA, cell-free translation, plasmids, cloning in bacteriophage lambda and a host of other things. It was therefore disappointing to find, for example, no description of nucleic acid hybridization directly in dried agarose gels or of the chemical synthesis of oligonucleotide probes.

But these are quibbles. Molecular biology now permeates so much of present research that a working knowledge of its methods can be essential; it is at once the queen and handmaiden of the biological sciences. The editor tells us that the intention was to collect descriptions of methods that would definitely work, particularly in the hands of novices, and I fancy that these books will rightly be welcomed in such quarters. They will not replace the fuller, more discursive treatments given by the originators of these techniques in, say, *Methods in Enzymology*. Nor perhaps will they have the impact of Cold Spring Harbor's celebrated *Molecular Cloning: A Laboratory Manual* by Maniatis *et al.* (now sadly getting out of date) which informed so many beginners in their first fumbling steps in recombinant DNA work some three years ago. However, if, as intended, these books enable those of stout heart but limited experience to gain entry to the growing battery of molecular biological methods, they will have served a useful purpose. □

Richard Perham is a Reader in the Department of Biochemistry, University of Cambridge, and President of St John's College, Cambridge.

Fields of physics

Graham G. Ross

Quantum Field Theory.
By F. Mandl and G. Shaw.
Wiley: 1984. Pp.354. Hbk £38, $34.95; pbk £19, $24.95.

CONSIDERING the importance of the subject, there has been a remarkable shortage of textbooks available for the student of field theory. For many years there were no significant texts to follow the pioneering, and excellent, accounts of Bjorken and Drell, and Schweber, and a very nice short book by Mandl. The situation has improved lately with the encyclopaedic work by Itzykson and Zuber, a very readable text by Ramond covering the path integral formalism and many others. It is in this context that Mandl and Shaw's *Quantum Field Theory* appears.

A pleasing feature of the book is that it is accessible to the new student, starting immediately with the Lagrangian formalism, and giving a detailed and careful treatment of quantum electrodynamics (QED). I liked the emphasis on performing explicit perturbative calculations and the implementation of the renormalization programme, although I was disappointed that the renormalization group is not discussed. Throughout, the text is augmented with worked examples and problems. It thus provides a welcome update of earlier textbooks on electrodynamics; it is more straightforward than Bjorken and Drell, more detailed than another recent introduction to the subject by Halzen and Martin, and should give both the experimental and theoretical student a good working knowledge of QED.

In its treatment of developments beyond QED the book has some shortcomings. There is no discussion of QCD, the non-Abelian gauge field theory for the strong interactions, and only a relatively short account of the gauge theory for the electroweak interactions. Indeed the concept of gauge invariance, central to modern developments in field theory, is only developed in Chapter 12 and the path integral formalism, which simplifies the analysis of spontaneously broken theories, is not covered. As a result the discussion of the electroweak theory is disappointing, particularly as it does not present a calculation in a spontaneously broken theory beyond the leading order, nor cover the renormalization in such theories. This renders the book less useful than it might have been for it is in this area that much progress has been made which is not yet adequately covered for the novice graduate student.

Mandl and Shaw have produced a sound introduction to the subject of Abelian gauge field theories which should also be useful as a reference text for perturbative calculations. However it provides only part of a modern introductory course and should be read together with another text, for example that of Ramond, which deals with the advances beyond QED. □

Graham G. Ross is in the Department of Theoretical Physics at the University of Oxford.

● After writing this review I received a second text on the same subject, *Quantum Field Theory* by Lewis H. Ryder (Cambridge University Press; £40, $74.50). The similarity to Mandl and Shaw ends with the title, for Ryder provides an introduction to many of the recent advances in field theory, using the path integral formalism to derive Feynman rules for spontaneously broken non-Abelian gauge theories and including a discussion of some of the topological properties and solutions of these theories. The approach differs too, with emphasis on the more formal aspects, no problems and few worked examples. The book is quite readable and is a good introductory text suitable for a theory student, but is probably best read after Ramond's book. In many ways it complements Mandl and Shaw, although the lack of worked examples will be hindrance to the student wanting a full understanding of the subject, and again there is no explicit calculation presented for a spontaneously broken gauge theory. G.G.R.

Real and Functional Analysis, 2nd Edn. Part A, Real Analysis. By A. MUKHERJEA and K. POTHOVEN. *Plenum· 1984 Pp 364 ISBN 0-306-41557-7 Np.*

Sets, Relations and Mappings. By T.S. BLYTH and E.F ROBERTSON. *Cambridge University Press: 1984. Pp 97. Pbk ISBN 0-521-27285-8 Pbk £3.50.*

A Survey of Trace Forms of Algebraic Number Fields. By P E CONNER and R. PERLIS *Wiley: 1984. Pp. 316. Pbk ISBN 9971-966-05-0. Pbk £17.65.*

Theory and Applications of Linear Differential and Difference Equations: A Systems Approach in Engineering. By R M. JOHNSON *Halstead: 1984 Pp 183. ISBN 0-470-20106-1. £18 50, $24.*

Astronomy

Beyond the Black Hole: Stephen Hawking's Universe. By JOHN BOSLOUGH. *Collins: 1985 Pp 126. ISBN 0-00-217138-4 £7 95*

Comets: A Descriptive Catalog. By GARY W. KRONK. *Enslow: 1984 Pp. 329. Pbk ISBN 0-89490-071-4. Pbk £15 50.*

The Cosmic Cycle. By THEODORE P. SNOW *Darwin Press, Box 2202, Princeton, NJ 08540: 1984 Pp. 109 ISBN 0-87850-041-3 $19.95*

Gamma Ray Astronomy. By RODNEY HILLIER. *Oxford University Press: 1984 Pp 202. ISBN 0-19-851451-4. £19.*

Sternbilder: Blicke in den Nachthimmel. By ARGYRIS SFOUNTOURIS *Ex Libris 1984 Pp 111 Fr 38*

Physics

Asymptotic Behaviour of Mass and Spacetime Geometry. FRANCIS J. FLAHERTY (ed) *Springer-Verlag: 1984. Pp. 213 Pbk ISBN 3-540-133351-8/0-387-13351-8 DM 30.*

Atmospheric Electrodynamics. By HANS VOLLAND. *Springer-Verlag: 1984. Pp 205 ISBN 0-387-13510-3/3-387-13510-3. DM 98, $35.70*

Coulomb Liquids. By N.H. MARCH and M P TOSI *Academic 1984. Pp 351 ISBN 0-12-470520-0 $59, £35.*

Electron Correlation in Molecules. By S. WILSON. *Oxford University Press· 1984. Pp 281 ISBN 0-19-855617-9 £40*

Electronic Properties of Doped Semiconductors. By B.I SHKLOVSKII and A.L EFROS *Springer-Verlag: 1984 Pp. 388. ISBN 3-540-12995-2/0-487-12995-2 DM 128, $50.20.*

Field Theory, the Renormalization Group, and Critical Phenomena. By DANIEL J. AMIT. *Wiley: 1984. Pp. 394. Pbk ISBN 0-9971-966-11-5 £25.30*

Gravitation and Relativistic Astrophysics. A R. PRASANNA, J.V. NARLIKAR and C V. VISHVESHWARA (eds). *Indian Academy of Sciences/Wiley: 1984. Pp. 151. ISBN 9971-966-67-0. £27 60*

Harmonic and Minimal Maps with Applications in Geometry and Physics. By GÁBOR TÓTH *Halsted· 1984. Pp. 342. ISBN 0-470-20127-4. £30, $39.*

Physical Acoustics, Vol. XVIII. WARREN P. MASON and R N. THURSTON (eds). *Academic. 1984 Pp. 326. ISBN 0-12-477917-4. $89, £62 50.*

Physics and Contemporary Needs, Vol. 6. A M KHAN *et al.* (eds). *Plenum: 1984 Pp. 465. ISBN 0-306-41631-X $75.*

Position-Sensitive Detection of Thermal Neutrons. PIERRE CONVERT and J BRUCE FORSYTH (eds). *Academic. 1984 Pp. 430 ISBN 0-12-186180-5 $36, £21*

Quantum Electrodynamics and Quantum Optics. A.O. BARUT (ed). *Plenum· 1984 Pp 471. ISBN 0-306-41730-8. $75.*

Semiconductor Contacts: An Approach to Ideas and Models. By HEINZ K. HENISCH *Oxford University Press 1984. Pp 377. ISBN 0-19-852016-6. £48.*

Theory of Molecular Fluids. Vol. 1 Fundamentals By C G. GRAY and K.E. GUBBINS. *Oxford University Press 1984 Pp. 626. ISBN 0-19-855602-0. £60.*

Theory of Neutron Scattering from Condensed Matter, Vols 1 & 2. By STEPHEN W LOVESEY. *Oxford University Press: 1984. Vol. 1: pp.329, ISBN 0-19-852015-8, £38, Vol 2 pp.344, ISBN 0-19-852017-4, £38.*

Technology

Chemical Reaction Engineering. INSTITUTION OF CHEMICAL ENGINEERS *Pergamon 1984 Pp. 826 ISBN 0-08-030283-1. £55, $77*

Developing Expert CAD Systems. By VIVIENNE BEGG. *Kogan Page: 1984. Pp. 118. ISBN 0-85038-818-X. £11 95*

Introduction to Food Engineering. By R PAUL SINGH and DENNIS R. HELDMAN *Academic· 1984 Pp. 306. ISBN 0-12-546380-8. $35, £26.50*

Methods and Materials in Microelectronic Technology. JOACHIM BARGON (ed.). *Plenum· 1984. Pp. 367 ISBN 0-306-41803-7. $59.50.*

Practical Problems in Soil Mechanics and Foundations Engineering, 1. By GUY SANGLERAT, GILBERT OLIVARI and BERNARD CAMBOU *Elsevier. 1984. Pp. 283. ISBN 0-444-42108-4. Np*

Transducers in Measurement and Control, 3rd Edn. By PETER H SYDENHAM. *Adam Hilger: 1984. Pp. 122. Pbk ISBN 0-85274-777-2. £12.95, $19*

Chemistry

Advances in Heterocyclic Chemistry. ALAN R. KATRITZKY (ed.) *Academic: 1984. Pp. 416 ISBN 0-12-02063606. $95, £66 50*

Allenes in Organic Synthesis. By HERBERT F. SCHUSTER and GARY M. COPPOLA *Wiley· 1984. Pp. 358. ISBN 0-471-87284-9. £54.95.*

Asymmetric Synthesis, Vol. 4. The Chiral Carbon Pool and Chiral Sulfur, Nitrogen, Phosphorus, and Silicon Centres. JAMES D. MORRISON and JOHN W. SCOTT (eds). *Academic. 1984 Pp 380. ISBN 0-12-507704-1 $85, £64*

Gas Phase Ion Chemistry, Vol. 3. Ions and Light. MICHAEL T. BOWERS (ed). *Academic· 1984 Pp. 453. ISBN 0-12-120803-6. $75, £58.*

Starch: Chemistry and Technology, 2nd Edn. ROY L. WHISTLER, JAMES N. BEMILLER and EUGENE F. PASCHALL (eds) *Academic: 1984. Pp. 718 ISBN 0-12-746270-8 $75, £53.50.*

Structure – Property Relationships in Polymers. By RAYMOND B. SEYMOUR and CHARLES E. CARRAHER. *Plenum: 1984 Pp 232 ISBN 0-306-41650-6. $22.50*

Surface and Colloid Science. EGON MATIJEVIĆ and ROBERT J. GOOD (eds). *Plenum: 1984. Pp 297 ISBN 0-306-41322-1. $45.*

Water Analysis. Vol. III Organic Species. ROGER A. MINEAR and LAWRENCE H KEITH (eds) *Academic: 1984. Pp 456. ISBN 0-12-499303-0. $69, £48.50*

Earth Sciences

Arid Australia. H G. COGGER and E.E CAMERON (eds). *Australian Museum 1984. Pp 338. Pbk ISBN 0-7305-0222-8. Pbk A$11.*

Fine-Grained Sediments: Deep-Water Processes and Facies. D.A V. STOW and D.J.W PIPER (eds) *Blackwell Scientific. 1984. Pp. 659 ISBN 0-632-01075-4. £65*

Soils and Geomorphology. By PETER W. BIRKELAND *Oxford University Press: 1984. Pp. 372. Pbk ISBN 0-19-503435-X. Pbk £14.95.*

Stochastic Modelling of Ocean Dynamics. By I E TIMCHENKO. *Harwood: 1984. Pp. 311. ISBN 3-7186-0231-8 $135*

Biological Sciences

Acquired Immune Deficiency Syndrome. MICHAEL S. GOTTLIEB and JEROME E. GROOPMAN (eds) *Alan R. Liss: 1984. Pp. 438. ISBN 0-8451-2615-6 £46.*

Advances in Immunology, Vol. 36. FRANK J. DIXON (ed.) *Academic· 1984 Pp 248 ISBN 0-12-022436-4 $36 50, £26.*

Advances in Inorganic and Bioinorganic Mechnisms. A.G SYKES (ed.). *Academic 1984. Pp.388. ISBN 0-12-023802-0. $75, £48.*

Advances in Radiation Biology. JOHN T. LETT (ed.). *Academic. 1984. Pp 440. ISBN 0-12-0354110-X. $75, £52.50.*

Alkaloids: Chemical and Biological Perspectives, Vol. 2. S WILLIAM PELLETIER (ed) *Wiley 1984. Pp. 490 ISBN 0-471-89299-8 £69.35.*

Allelopathy, 2nd Edn. By ELROY L. RICE *Academic. 1983. Pp. 422. ISBN 0-12-587055-8. $55, £42 50*

Animal Reproduction: Parents Making Parents. By JACK COHEN and BRENDAN MASSEY. *Edward Arnold: 1984 Pp. 76. Pbk ISBN 0-7131-2904-2. Pbk £3 50*

Anti-Zufall: Die Gesetzmassigkeit der Evolution biologischer Systeme. By ERNEST SCHOFFENIELS *S. Hirzel· 1984 Pp 152 Pbk ISBN 3-776-0402-X DM 28.*

Aphids on the World's Crops: An Identification Guide. By R L BLACKMAN and V F. EASTOP. *Wiley 1984 Pp. 466 ISBN 0-471-90426-0. £40*

The Bacterial Spore, Vol. 2. A HURST and G.W. GOULD (eds). *Academic: 1984. Pp. 328. ISBN 0-12-293652-3. $52, £32*

Basement Membranes and Cell Movement. *Pitman. 1984 Pp 285 ISBN 0-272-79778-2 £26 50*

Biochemistry of Steroid Hormones, 2nd Edn. H.L.J. MAKIN (ed.). *Blackwell Scientific· 1984. Pp. 714. ISBN 0-632-00986-1 £75*

Biodynamics Circulation. By Y C FUNG. *Springer-Verlag: 1984 Pp 404. ISBN 3-540-90867-6/0-387-90867-6 DM 92, $36.60*

Biological Dosimetry: Cytometric Approaches to Mammalian Systems. W G. EISERT and M L. MENDELSOHN (eds) *Springer-Verlag 1984. Pp. 346 Pbk ISBN 3-540-12790-9/0-387-12790-9. Pbk DM 68, $24.80.*

Biology of Meiofauna. C. HEIP (ed.). *Dr W. Junk 1984 Pp. 133. ISBN 90-6193-513-X Np.*

Biorhythms 1 and 2. Basic Biology set to Words and Music. 1, Human Biology. 2, General Biology Words by HAROLD BAUM Music by PETER SHADE. *Taylor and Francis· 1984 £8.95 each.*

Blood Vessels and Lymphatics in Organ Systems. DAVID I. ABRAMSON and PHILIP B. DOBRIN (eds). *Academic. 1984 Pp. 771. ISBN 0-12-042520-3 $89, £69*

Bone, Antler, Ivory and Horn: The Technology of Skeletal Materials Since the Roman Period. By ARTHUR MacGREGOR. *Croom Helm: 1984. Pp 245 ISBN 0-7099-3242-1. £35.*

Brain Receptor Methodologies. PAUL J MARANGOS, IAIN C. CAMPBELL and ROBERT M. COHEN (eds) *Academic· 1984 Pp 363 $56, £39.50*

Brain Receptor Methodologies. Part B Amino Acids, Peptides, Psychoactive Drugs. PAUL J. MARANGOS, IAIN C. CAMPBELL and ROBERT M. COHEN (eds). *Academic: 1984. Pp 336. ISBN 0-12-470352-6. $45, £31.50.*

Carcinoma of the Esophagus and Gastric Cardia. GUO JUN HUANG and WU YING K'AI (eds). *Springer-Verlag: 1984. Pp 395. ISBN 3-540-12535-3/0-387-12535-3 DM 298, $108 50*

Cell Ageing and Cell Death. I. DAVIES and D C SIGEE (eds). *Cambridge University Press 1984. Pp. 362 ISBN 0-521-26172-4 £22.50.*

Cellular Interactions. H.F LINSKENS and J. HESLOP-HARRISON (eds) *Springer-Verlag: 1984. Pp.743. ISBN 3-540-12738-0/0-387-12738-0 DM 360*

Cellular and Molecular Neurotoxicology. TOSHIO NARAHASHI (ed.). *Raven· 1984 Pp 304. ISBN 0-88167-028-6 $67.*

Cerebral Cortex. Vol. 2 Functional Properties of Cortical Cells EDWARD G JONES and ALAN PETERS (eds) *Plenum· 1984 Pp.340. ISBN 0-306-41755-3. $42.50.*

Chloroplast Biogenesis. R.J ELLIS (ed) *Cambridge University Press: 1984 Pp.346. ISBN 0-521-24816-7. £36.*

Compartments in Algal Cells and Their Interaction. W. WIESSNER, D.G. ROBINSON and R.C. STARR (eds). *Springer-Verlag:1984. Pp.241. ISBN 3-540-13318-6/0-387-13318-6. DM 98, $35.70.*

Comprehensive Virology. HEINZ FRAENKEL-CONRAT and ROBERT R. WAGNER (eds). *Plenum. 1984 Pp.536 ISBN 0-306-41698-0 $69.50.*

Connective Tissue Matrix. DAVID W.L. HUKINS *Macmillan, London: 1984 Pp.245. ISBN 0-333-33372-1. £35*

Culture, Feeding and Diseases of Commercial Flatfish Species. By E W LIEWES. *Balkema: 1984. Pp 104 ISBN 90-6191-291-1 $18 50, £11.*

Current Topics in Membranes and Transport, Vol. 20. Molecular Approaches to Epithelial Transport. JAMES B WADE and SIMON A. LEWIS (eds). *Academic: 1984. Pp.324. ISBN 0-12-153320-4. $58, £41.50*

Darwin Pedigrees. By R B. FREEMAN *Privately printed by author at University College London. 1984. Pp.84. Np.*

The Electrophysiology of Intellectual Functions. By DUILIO GIANNITRAPANI *Karger. 1985. Pp.247. ISBN 3-8055-3878-2. DM 196, $98.25.*

Environmental Stress and Behavioural Adaptation. By JOHN DAVENPORT. *Croom Helm· 1984. Pp.122 Hbk ISBN 0-7099-0829-6, pbk ISBN 0-7099-0854-7 Hbk £14 95, pbk £6.95.*

Evolution of Jaw Mechanisms in Ornithopod. By DAVID B. WEISHAMPEL. *Springer-Verlag: 1984. Pp.108 Pbk ISBN 3-340-13114-0/0-387-13114-0. DM 54.*

Evolution: A Modern Synthesis. By W.H. DOWDESWELL. *Heinemann. 1984. Pp.176. Pbk ISBN 0-435-60227-6. Pbk £6.50*

Evolution and Tumour Pathology of the Neuroendocrine System. STURE FALKMER, ROLF HAKANSON and FRANK SUNDLER (eds) *Elsevier: 1984. Pp.599. ISBN 0-444-80560-5. $146, Dfl 380.*

Flowers of the Himalaya. By OLEG POLUNIN and ADAM STAINTON. *Oxford University Press: 1984 Pp.580 ISBN 0-19-217623-4. £29 50*

Folates and Pterins. By RAYMOND L BLAKLEY and STEPHEN J. BENKOVIC. *Wiley: 1984 Pp.628. ISBN 0-471-87586-4. £115.*

Frontiers in Cardiology for the 80's. L. DONATO and A. L'ABBATE (eds) *Academic: 1984. Pp.332 ISBN 0-12-220680-0. $45, £30*

Genes and Cancer. J. MICHAEL BISHOP, JANET D. ROWLEY and MEL GRAVES (eds) *Alan R Liss: 1984. Pp.710 ISBN 0-8451-2626-4. £67.*

Genetic Maps 1984, Vol. 3. STEPHEN J. O'BRIEN (ed.). *Cold Spring Harbor·1984. Pp.584. Pbk ISBN 0-87969-171-0. Pbk $28.*

Gillies and Dodds Bacteriology Illustrated, 5th Edn. Revised by R.R. Gillies *Churchill Livingstone:1984. Pp 224. Pbk ISBN 0-443-02809-5 Pbk £15.*

The Handbook of Complementary Medicine. By STEPHEN FULDER *Coronet·1984 Pp 368. Pbk ISBN 0-340-32113-X Pbk £5.95*

Handbook of Mental Illness in the Mentally Retarded. FRANK J. MENOLASCINO and JACK A. STARK (eds) *Plenum:1984 Pp 456 ISBN 0-306-41648-4. Np.*

Hematopoiesis. DAVID W. GOLDE *Churchill Livingstone:1984 Pp.361 ISBN 0-443-08286-3 £30*

Hugh Johnson's Encyclopaedia of Trees. By HUGH JOHNSON. *Mitchell Beazley:1984 Pp.336. £19.95.*

Human Abilities: An Information-Processing Approach. ROBERT J STERNBERG (ed.). *W H Freeman:1984. Pp.259. Pbk ISBN 0-7167-1619-4. Pbk $13.95.*

Immunobiology of HLA Class-I and Class-II Molecules. R.R.P. de VRIES and J J van ROOD (eds). *Karger.1984. Pp.226. ISBN 3-8055-3893-6 DM 146, $73.*

Immunotoxicology. G. GORDON GIBSON, RONALD HUBBARD and DENNIS V. PARKE (eds). *Academic:1984. Pp.505. ISBN 0-12-282-180-7. $32, £19 60.*

Impedance Microbiology. By RUTH and GIDEON EDEN. *Wiley.1984. Pp.170. ISBN 0-471-90623-9. £24.50.*

Insect Conservation: An Australian Perspective. By T.R. NEW. *Dr W. Junk: 1984. Pp. 184. ISBN 90-6193-507-5. Np.*

International Review of Cytology, Vol. 90. G.H. BOURNE and J.F. DANIELLI (eds). *Academic: 1984. Pp.383 ISBN 0-12-364490-9. $52 50, £37.*

Internatinal Review of Cytology, Vol. 91. Membranes. J F. DANIELLI (ed.). *Academic:1984. Pp.195. ISBN 0-12-364491-7. $36.50, £26*

Lower Plants: Anatomy and Activities of Non-Flowering Plants and Their Allies. By C.J. CLEGG. *John Murray:1984. Pp.96. Pbk ISBN 0-7195-4010-0. Pbk £6.95*

The Measurement of Human Growth. By NOEL CAMERON. *Croom Helm.1984. Pp.182. ISBN 0-7099-0731-1. £15.95.*

Mechanisms of Intestinal Electrolyte Transport and Regulation by Calcium. MARK DONOWITZ and GEOFFREY W.G. SHARP (eds). *Alan R. Liss:1984. Pp.374. ISBN 0-8451-0307-5. £60*

Metal Ions in Biological Systems, Vol. 18. HELMUT SIGEL (ed.). *Dekker:1984 Pp.432. ISBN 0-8247-7226-1. $79 75, SwFr. 212*

Microbial Development. RICHARD LOSICK and LUCY SHAPIRO (eds). *Cold Spring Harbor.1984. Pp.303. Pbk ISBN 0-87969-173-5 Pbk $28*

Modeling and Analysis in Biomedicine. C. NICOLINI (ed.) *Wiley·1984. Pp 539 ISBN 9971-950-81-2. £63.90.*

Modern Cell Biology, Vol 3. BIRGIT H. SATIR (ed) *Alan R Liss 1984. Pp.280. ISBN 0-8451-3302-0. £38.*

Molecular Biophysics of the Extracellular Matrix. STRUTHER ARNOTT, D A. REES and E.R. MORRIS (eds). *Humana:1984. Pp 189.ISBN 0-89603-051-2. $39.50.*

The Mollusca, Vol. 7. Reproduction. A S TOMPA, N H VERDONK and J.A.M. VAN DEN BIGGELAAR (eds) *Academic 1984. Pp.486 ISBN 0-12-751407-4 $55*

Mucus and Mucosa. Ciba Foundation Symposium 109 *Pitman:1984 Pp.246. ISBN 0-272-79783-9. £26.50, $35*

Mycorrhizal Symbiosis. By J L. HARLEY and S.E. SMITH. *Academic:1983 Pp.483. ISBN 0-12-325560-0 $59 50, £35*

Myxobacteria: Development and Cell Interactions. EUGENE ROSENBERG (ed.) *Springer-Verlag.1984. Pp.301. ISBN 3-540-90962-1/0-387-90962-1. DM 148, $52.*

Nest Building and Bird Behaviour. By NICHOLAS E COLLIAS and ELSIE C COLLIAS *Princeton University Press:1984. Pp.336. ISBN 0-691-08358-4. Hbk £44.80, pbk £12 70.*

Neurotransmitter Receptor Binding. HENRY I YAMAMURA, S J. ENNA and MICHAEL J. KUHAR (eds). *Raven:1984. Pp.242. ISBN 0-88167-027-8 $58*

Non-Invasive Physiological Measurements, Vol. 2. By PETER ROLFE. *Academic:1984. Pp.383 ISBN 0-12-593402-5. $67 50, £39.50*

Nutrition, Hypertension and Cardiovascular Disease. By RONALD S SMITH *Lyncean Press, 885 Eight Street, Gilroy, CA 95020, USA:1984. Pp.210. $12.95.*

Perspectives in Methodology for Studies of the Microcirculation. K. MESSMER *et al.* (eds) *Karger.1984. Pp.159 Pbk ISBN 3-8055-3988-6. Pbk SwFr. 74, DM 89, $44.50.*

Perspectives on Plant Population Ecology. RODOLFO DIRZO and JOSÉ SARUKHÁN (eds). *Blackwell Scientific· 1984 Pp. 478. Hbk ISBN 0-87893-142-2; pbk ISBN 0-87893-143-0 Hbk £37.50, pbk £22.50.*

Physiological Strategies in Lactation. M. PEAKER, R G VERNON and C H. KNIGHT (eds) *Academic:1984. Pp.432. ISBN 0-12-613351-4. $48, £30*

Prolactin Secretion: A Multidisciplinary Approach. FLAVIO MENA and CARLOS M VALVERDE-R (eds). *Academic:1984. Pp.432 ISBN 0-12-490620-6. $44.50, £31*

Proteins Involved in DNA Replication. Advances in Experimental Medicine and Biology, Vol. 179. ULRICH HÜBSCHER and SILVIO SPADARI (eds). *Plenum·1984. Pp.571. ISBN 0-306-41804-5. $85.*

Psychosocial Stress and Cancer. CARY L. COOPER (ed.). *Wiley: 1984. Pp 265. ISBN 0-471-90477-5. £17*

Psylloidea of South Australia. By F. DAVID MORGAN. *The South Australian Museum, North Terrace, Adelaide, SA 5000·1984. Pp.136. Pbk ISBN 0-7243-4560-4. Np.*

Pulmonary Surfactant. BENGT ROBERTSON, LAMBERT M.G. VAN GOLDE and JOSEPH J BATENBURH (eds). *Elsevier:1984. Pp.582. ISBN 0-444-80553-1. $134 50, Dfl. 350.*

Red Sea Shells. By DOREEN SHARABATI. *Routledge & Kegan Paul. 1984. Pp.127. ISBN 0-7103-0103-0 £10.*

Respiratory Distress Syndrome. KARI O. RAIVIO *et al* (eds). *Academic:1984. Pp.421. ISBN 0-12-576180-5 $55, £32.*

Role of the Envelope in the Survival of Bacteria in Infection. C.S.F. EASON *et al* (eds) *Academic:1984 Pp.264. ISBN 0-12-228003-2. $47.*

Secondary Metabolism in Microorganisms, Plants, and Animals, 2nd Edn. By MARTIN LUCKNER *Springer-Verlag:1984. Pp.576. ISBN 3-540-12771-2/0-387-12771-2. DM 124, $43.60.*

Seminal Vesicles and Fertility: Biology and Pathology. C. BOLLACK and A. CLAVERT (eds). *Karger 1984 Pp 182. ISBN 3-8055-3907-X. DM 178, $89.25*

Storage Carbohydrates in Vascular Plants: Distribution, Physiology and Metabolism. D.H LEWIS (ed.) *Cambridge University Press:1984. Pp.284. ISBN 0-521-23698-3. £35*

The Undersea Predators. By CARL ROESSLER *Facts on File: 1984 Pp 192. ISBN 0-87196-893-2. $24.95.*

Variants of Human Fibrinogen. E.A BECK and M FURLAN (eds). *Hans Huber: 1984. Pp 328 Pbk ISBN 3-456-81359-7 DM 116.*

General

Brines and Evaporites. By PETER SONNENFELD *Academic. 1984 Pp. 613. ISBN 0-12-654780-7. $75, £57 50.*

AN EXPERIMENT WITH TIME

J. W. DUNNE

"J. W. Dunne's predictive dreams, and his explanation within the time concepts of modern physics, are as fascinating today as they were when first published half a century ago." Sir Bernard Lovell

"Few works of non-fiction . . . have attracted so large and diverse a readership . . . few are remembered today with such affection; and few have been so influential . . ." Brian Inglis

In 1927 J. W Dunne published a book which was to inspire and excite generations of readers intrigued by that most fascinating paradox – Time. His speculations and conclusions are as fascinating and thought-provoking today as they were when first published.

Now available in paperback at £3.50

COMPUTING FOR BIOLOGISTS

Alan Fielding

Very few books on computing are written specifically for biologists Most are dedicated to students of computer science and engineering This new text introduces the basic concepts of computers and programming from a biologist's viewpoint The main part of the text is a gentle introduction to BASIC, illustrating the concepts with biological examples, from common statistical techniques for fairly sophisticated modelling (of Animal Competition) The book concludes with a survey of information technology, data storage, graphics and the use of advanced software packages in biological research

Contents

Introduction to biological computing, Programming languages, Introduction to BASIC, Loops and arrays, Functions, Program control structures, Strings, Disks, files and operating systems, Computer graphics and image processing, Structured programming, Computer models, Information technology, Working with mainframe computers, Program optimization, Summary, Appendix 1 Number storage systems and sources of error, Appendix 2 ASCII conversion table, Appendix 3 Interfacing to microcomputers, Appendix 4 Answers to selected problems, Appendix 5 Bibliography

1985/204pp/illus/0 201 14574 X/£8 95 paper

ANNOUNCE

STATSTREAM

Statistics and much more for the Apple II series . . .

This great-value package of two disks and manual is a powerful tool for numerical analysis of data by scientists, economists, etc., and for teaching of numerical analysis to students in many disciplines.

At its heart are 76 procedures including: KEYIN (enter and edit data), ADRW (draw and annotate graphs), WINDW (open or close a text window), MOVE (display and disk file data), MEANRE (find the mean of a column of data), TTEST (Student's *t* test) MANNWHITNEY (use Mann Whitney test), FFITTER (fit a non-linear function to data), PSEUD (generates pseudodata), etc., etc. These can be used very simply by:

(1) Calling the user-friendly, menu-driven Statpack, which enables a variety of parametric and non-parametric tests to be done after a single entry of data.

(2) Using the 32 demonstration programs designed to teach the user all about statistics and fitting functions to data.

(3) Writing straightforward BASIC programs to incorporate the desired procedures.

For the technically minded

Disk 1 contains the boot programs which. (1) modify resident Applesoft BASIC to accept STATSTREAM commands The commands include procedure calls (USE NAME will invoke the named procedure, automatically overlaying it from disk if necessary), IF–THEN–ELSE–ENDIF, REPEAT–UNTIL, etc (2) Permit up to 5 text windows The machine code snaps windows open and shut The window command can be invoked from your own BASIC STATSTREAM program (3) Shape tables to assist graphics.

Plus 32 example programs and the Statpack which is based on STATSTREAM commands which, in this mode, are each called with a single keystroke

Disk 2 contains the library of STATSTREAM commands When a command is used, the appropriate procedure is automatically loaded into memory, executed and forgotten Commands can be executed immediately or included in BASIC programs For example all that is required to retrieve a STATSTREAM data file is

```
]USE MOVE,1,1,1,1
```

The parameters specify the left-most and right-most columns and top-most and bottom-most rows In this case they are dummies because the data file itself will dictate the size of the data table and the data array will be dimensioned automatically Array sizes are checked and altered if necessary The MOVE command is typical of STATSTREAM commands It opens a window, displays a menu, allows the user to interact (choose filename, display data, etc) and finally snaps the window closed

Once the data are in memory any other command can be used in immediate mode, e.g

```
]USE MEANRE,1 – finds the mean of column 1
]USE ADRW,1,2,10,1, "DEMO", "X-AXIS", "Y-AXIS"
        – draws a graph of 10 rows of column 2 against column 1 using a line and annotates it
```

A simple program which allows 2 columns of data, each of 10 rows to be input, computes the logarithm of column 2, graphs it, calculates linear regression, graphs line with residuals and errors would consist of

```
]10 DIM RE(2,20) .REM sample BASIC program utilizing STATSTREAM commands
]20 USE KEYINQ,1,2,1,10
]30 FOR I=1 TO 10 ·RE(1,2)=LOG(RE(1,2)) ·NEXT I
]40 USE RESFIT,1,2,0
]30 END
```

It can be seen that STATSTREAM has a uniform syntax at both command and program level, and since the commands interact through transient windows they do not interfere with your own screen layout

STATSTREAM includes the following command procedures for statistical methods, and more can easily be added:

Mean, standard deviation, standard error and confidence interval
Student's *t* test, ANOVA one way, ANOVA two way, F test
Linear regression, correlation
χ^2 (chi-squared) test, contingency tables
Median, non-parametric confidence interval
Signtest, Wilcoxon signed rank test, Mann-Whitney test
Kruskal Wallis, Friedman t-test, F test
Pseudodata generators for Gaussian, skewed noise, etc.
Minimization routines for non-linear function fitting and solving equations

STATSTREAM can be used to analyse data in pre-existing Apple data files and it also has a routine for using Viscalc files.

Two 5.25" disks for the Apple II (can be used with one or two disk drives) plus comprehensive manual ***US $99; UK £66***

Reader Service No.04

Computer applications

These pages feature computer hardware and software for the automated laboratory, from a 'metabolic computer' to a Digital Paintbrush graphics package.

● BALANCE, a new statistical software package from Elsevier Scientific, makes it possible to compare two series of measurements. BALANCE determines whether the means of two series of measurements are significantly different. The package can be used, for example, in comparing the results of two different medical treatments, investigating the effect of a drug, or of two analytical methods. This kind of comparison is probably the most frequently used statistical technique in industrial, clinical, chemical and quality control laboratories. BALANCE guides the operator automatically to the correct statistical test; it does not require knowledge of the statistical background by the user. BALANCE incorporates the following tests: tests for small numbers and for large numbers of observations; independent and related (paired) tests; one- and two-tailed (sided) tests; Student's *t*- and Cochran's tests (parametric tests); and Wilcoxon's matched-pairs signed-rank test and Mann-Whitney's *U*-test (non-parametric tests).
Reader Service No. 100.

Stat-Attack, an anti-static computer cleaning system.

● Zenith's Electronics' Service, Parts and Accessories Division has introduced Stat-Attack, an anti-static computer cleaning system packaged in a convenient tray that doubles as a desk/shelf organizer. The Stat-Attack system contains an anti-static spray that protects equipment from static discharge. It can be sprayed directly onto printers and other static-generating computer equipment. When fitted with a special extension, it can be lightly sprayed onto carpets or countertops. It converts lint-free wipers (included in the system kit) into static neutralizing cloths.
Reader Service No. 101.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

A microcomputer, the CompuPro 816/C from Viasyn Corporation of California, is used to maintain a complete database on the behaviour and physical condition of Ling-Ling, the Giant Panda in the US National Zoological Park. This assists in determining her oestrous period, and hence the best time for breeding. (Picture courtesy of the Zoological Society of London.)
Reader Service No. 99.

● The IBM PC microcomputer can now be used as a sophisticated data acquisition and control system for laboratory instruments using the ADALAB-PC from Interactive Microware Inc. A wide range of scientific instruments — including chromatographs, spectrometers, strip chart recorders, temperature controllers and *p*H meters — may be controlled by the ADALAB-PC using the specially designed ADAPT software which includes a menu-driven data acquisition program. The system provides accurately-timed collection of multiple data values; fast analog-to-digital (A/D) voltage sampling with direct memory access; data storage and retrieval from an extended RAM memory up to 640K; and a scrolling strip chart data display. A complete self-test checking procedure is also featured. ADALAB-PC consists of a single plug-in card, enabling the computer to interface easily with the lab instrument. The IBM-compatible system joins the established ADALAB products for use with the Apple II micro.
Reader Service No. 102.

● Packard Instrument has developed an advanced network of gas chromatography instruments. A GC network of up to 12 satellite or conventional GCs and their accessories can be programmed and monitored from one central control station. The control station can be either the stand-alone Model 830 network manager or Packard's top-of-the-line Model 439 GC. The model 830 is a light and compact desk-top unit. Control software for a number of GC accessories, including Packard's One-Shot Samplers, is built into the control stations. Four models of satellite GCs are available, covering the complete range of analytical requirements.
Reader Service No. 103.

● The Oxymax-85 metabolic computer from Columbus Instruments simultaneously measures: oxygen consumption, CO_2 production, respiratory quotient, respiration rate, relative tidal volume and temperature in one to four animal cages. The IBM-PC personal computer is used for data collection as well as a main system controller. An electronic laminar flowmeter is used at the input of each animal cage to ensure accurate measurement of air supply, and an electronic barometer, thermometer and hygrometer allow presentation of results in STP units, standardized to 760 mmHg, zero humidity and zero (°C) temperature. Results of measurements are printed at 1-min intervals, and Oxymax 85 is designed for 24-hour uninterrupted operation.
Reader Service No. 104.

● A new option has been introduced for ChemGraf, a chemical modelling package based on the DEC VAX minicomputer. The new option is ChemGuide, an artificial intelligence program designed principally for novice and casual users of molecular modelling techniques. It helps the user to start using ChemGraf, select methodology, use specialist techniques, and tailor techniques to specific applications. Previously, only consultancy support could provide this assistance; support which is necessarily limited. Initially ChemGuide presents the user with a series of options. Depending on the option selected, ChemGraf commands are automatically executed, the user is asked for information, or is presented with a series of further options. ChemGraf systems, and the new ChemGuide program, are produced by Chemical Design Ltd.
Reader Service No. 105.

Computer-controlled spectrophotometry from Beckman Instruments.

● Latest in the Beckman Instruments, Inc. range of software is DATA CAPTURE, which interfaces the DU-50 series spectrophotometer with the IBM Personal Computer. The software is part of a PC software library that interfaces a wide variety of Beckman instruments to personal computers. Through the direct integration of spectral measurement and processing capability, data can be acquired, analysed, displayed, archived and reported on a single economical computer.
Reader Service No. 106.

● Epsilon Consultancy Ltd. is introducing a comprehensive software package to enable the Tablet Digitizer to be interfaced to a small computer so that the coordinate information produced by the Digitizer can be handled in a meaningful way. The true purpose of the software is to enable the user to make measurements of the material which has been digitized. The interface between digitizer and computer has been written to make use of the RS232 interface, because this interface is the most widely used one. By cabling the digitizer to the RS232 port in the computer, the user can start the software programs going and initiate a filing system by which the digitizations are stored in a manner which will make it easy, later on, to operate sorting methods on the files; calculations, tabulations and measurements can be done. The software can be expanded to handle special requirements, such as statistical comparisons between measurements.

● Two graphics packages designed specifically for scientists and engineers are now available on the IBM PC from Heyden Datasystems — Scientific Plotter-PC and Curve Fitter-PC. The Scientific Plotter-PC package plots graphs from data entered from disk, via the keyboard, or calculated by a user-defined equation. Axes are scaled according to the user's requirements, in either linear or logarithmic form, so that data are presented in the most suitable proportions. Plots may be superimposed in different colours; and there are 20 different plotting symbols in four size ranges to choose from. Variable-length error bars may be superimposed on the symbols. Curve Fitter-PC simplifies the fitting of a wide variety of curves to data which are input from disk or keyboard. The program automatically scales the plots and data, which may then be averaged and smoothed to reduce the number of points or average out background noise. Scientific Plotter-PC and Curve Fitter-PC are mutually compatible. Both packages are available in Apple II versions as well as the new versions on the IBM PC.
Reader Service No. 108.

Shown are examples of surfaces created with SURF and printed on a dot matrix printer. Figures show surface plot rotated 30 degrees (top, left), the same surface plot rotated 115 degrees (top, right), and this same surface plot rotated to 190 degrees (bottom, right).

Golden Graphics plotter output.

● Golden Graphics System is an integrated package that produces contour maps and three-dimensional surface plots, plus a variety of two-dimensional charts and graphs. Produced by Golden Software, Inc., the new package is designed to allow the user to visualize the implications of multivariate data. The Golden Graphics System consists of five applications: TOPO which creates contour maps; SURF which creates three-dimensional surface drawings, also known as block diagrams or fishnet plots; GRAFIT which creates *xy* graphs, bar charts, pie charts, line graphs, and scatter charts; QGRID which creates a regularly spaced grid from irregularly spaced data; and PLOTCALL which creates plots from plotting commands that have been placed in a data file. The Golden Graphics System may be used with either a monochrome display card or a graphics card. If a graphics card is installed, output may be previewed on the screen. The Golden Graphics System runs on the IBM AT, IBM PC, and compatibles and requires 128K bytes of memory and one disk drive. Over forty different dot matrix printers are supported.

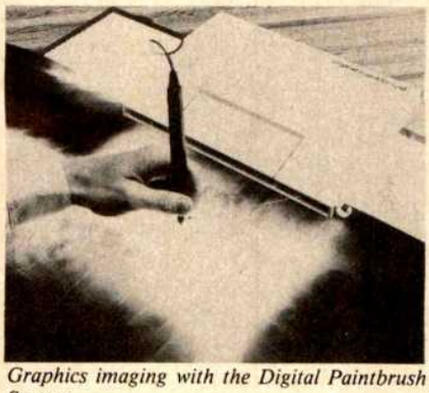
Photomail, from Chorus Data Systems.

● PhotoMail, available from Chorus Data Systems, allows PC users to capture images with a standard video camera or VCR and transmit them to a remote PC via ordinary phone lines. Still-frame pictures are sent at a resolution of up to 640 × 400 × 16 colours or levels of grey. PhotoMail operates with IBM PC, XT, AT and compatible computers. PhotoMail is icon-driven and supports voice communications so users can converse while an image is being displayed. By using a 'mouse' or the keyboard, each party can simultaneously point to a specific area of the picture and have a cursor displayed on both screens. By drawing with the mouse, users can designate specific areas of interest on the display. Images can also be annotated with text to allow users to label areas of interest, type messages and create image descriptions or specifications.
Reader Service No. 110.

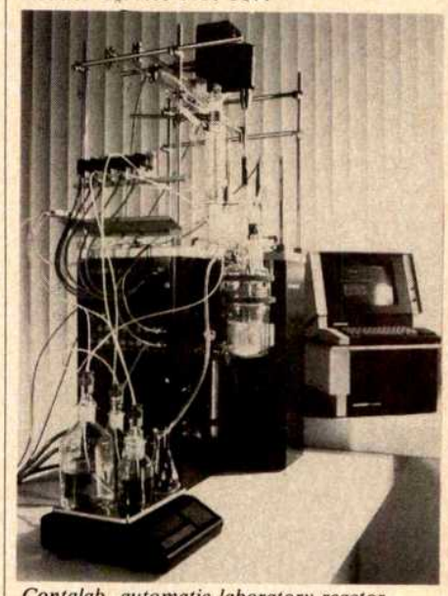


● Walonick Associates has introduced a new version of the statistical analysis program StatPac. The new package (V5.2) incorporates enhancements suggested by hundreds of StatPac users. Owners of the package will receive this update at no cost. The new features in StatPac include banner crosstabs, probit regression, principal components analysis with multicolinearity diagnostics, and new graphics. Walonick Associates is a computer software publishing firm that specializes in vertical application software. In addition to StatPac, the company offers Forecast Plus, a graphics time-series analysis package, and Mach, a chemical-dependency assessment program.
Reader Service No. 111.

● The Microlink modular interface has been enhanced to provide a comprehensive hardware and software solution in data acquisition and control. With the addition of 15 new modules, Microlink, from Biodata, offers a choice of more than 40 modules including analog and digital inputs/outputs, transducer inputs, timers and counters. The new modules include programmable gain amplifiers, transient capture devices, *p*H and RTD inputs, frequency/event counters and alarms. With the availability of new software for use with the HP150 and BBC, Microlink hardware can now be used with most popular micros — including IBM PC, Apricot, HP 80 series, HP 9816, Sirius and Apple. Sample programs are provided in BASIC for each of these computers.
Reader Service No. 112.

Digithurst's MicroEye interface for graphics display.

● Digithurst announce the release of a version of MicroSight I which will produce images on the Tecmar Graphics Card. The images are read into the IBM via the Digithurst's MicroEye interface and are held in random access memory as a 256 × 256 pixel file at 255 grey levels. Using the Tecmar Graphics Card, it is possible to display 16 of these levels at any one time. Although the increase in the display quality will primarily benefit users in the graphics field, it is expected that the ability to display more grey scales will also be of benefit to those using Digithurst's MicroScale packages for computerized image analysis.
Reader Service No. 113.



Graphics imaging with the Digital Paintbrush System.

● The Computer Colorworks, a San Francisco-based company, has introduced an IBM PC version of its Digital Paintbrush System, a complete hardware/software colour graphics package designed for the manipulation of graphical data. A more powerful, advanced version of the already popular Apple product, the new system is designed for scientific and professional users of the IBM PC, XT, AT, and compatibles. Graphic images made with the Digital Paintbrush can be shown like slides on a colour monitor or TV screen, printed as hard copy or as transparencies for overhead projection, and photographed with various hood cameras and picture processors (including the Polaroid Palette) to make 35-mm slides.
Reader Service No. 114.

● ALLOCATE is a software package from the UK division of Elsevier, designed for the organizers of animal experiments or clinical trials. ALLOCATE rapidly assigns clinical or experimental subjects to treatment groups. The random allocation, on the basis of a chosen parameter such as body weight, is repeated (with statistical tests to assess uniformity of groups performed automatically after each iteration) until criteria set at the outset are met, or the 'best allocation so far' is accepted. Full details of groups and statistical results can be displayed on-screen, and printed out. Unequal group sizes are catered for, and an optional cull facility enables outliers to be deleted. Manual and disk are available for the IBM PC, DOS 2.0. ILEUM is a package for the accurate simulation of the effects of drugs on the *in vitro* guinea pig ileum. Drugs available for the ILEUM simulation include a dozen familiar agonists (which will contract the muscle) together with blockers of various sorts. Experiments to identify an 'unknown compound' can be carried out, for which the computer selects, at random, one of 20 'unknowns'. Random elements are incorporated into ILEUM to simulate the biological variability of response to the same dose of agonist. It is available for Apple II, IBM PC and BBC B computers.
Reader Service No. 115.

● As an accessory to the Hewlett Packard 8451A UV/visible diode-array spectrophotometer, the new HP 89075A multicell transport automatically handles the concurrent measurement of up to seven samples over any length of time. The new transport provides accurate serial or random access to cells and is programmable, providing flexibility in method development. For applications such as kinetics, where multiple measurements must be taken and where data are acquired over long periods of time, the new product will deliver increased throughput and automated accuracy. The system mounts in the sample compartment of the HP 8451A spectrophotometer and uses standard 1-cm-square cuvettes and/or flow cells.
Reader Service No. 116.

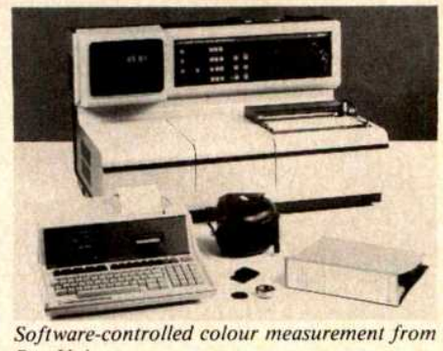
● Northwest Analytical, Inc. has introduced a new statistical quality control charting package, called QUALITY ANALYST, which provides the software for both process capability studies and process monitoring. The package is available for the IBM and compatibles, MS-DOS computers, Burroughs B20, CP/M and Apple's Macintosh. QUALITY ANALYST provides an effective alternative to time-share and minicomputer-based quality control systems. QUALITY ANALYST is a complete package and can be used effectively as a stand-alone system. It can interface with other software packages and be used as the analytical core of a workstation using other software such as databases and spreadsheets. QUALITY ANALYST works well with standard communications packages and can process information transmitted from a mainframe database.
Reader Service No. 117.

Contalab, automatic laboratory reactor.

● Contalab, recently introduced by Contraves, is a computer-controlled automatic laboratory reactor that can operate for 24 hours a day, completely unsupervised. Complete reactions can be performed and monitored automatically and a simple question-and-answer dialogue guides the operator through all data entry procedures. The computer controls the experiment, compiles all the data, and produces a record of all results. The system automatically assigns alarm limits to enable 24-h operation. Contalab is especially suited to experiments which must be repeated many times or performed consecutively with minor changes (serial tests and optimization for example). Contalab consists of a reactor assembly with balance (for use in a laboratory fume cupboard), control unit with dual disk drive, peripheral equipment for data input and output, and software package (for controlling system operation and processing sequences). The reactor assembly is equipped as standard with a 1-litre reaction vessel, a reflux condenser and a stirrer.
Reader Service No. 118.

● Kratos Analytical's new DS 650 allows real-time data acquisition and system control for chromatography and data management. The DS 650 hardware is based on Data General's model 10/SP desk-top microcomputer and includes a 15 MB Winchester hard disk, one 368 KB diskette drive, 256 KB of main memory, a 12-inch green monochrome bit-mapped monitor, a graphics printer, and a multiplexed A/D converter. This converter is capable of accepting data simultaneously from up to eight detectors, using four separate times bases. The computer's menu-driven software guides the user.
Reader Service No. 119.

● Nelson Analytical Inc. of Cupertino, California, has developed an advanced chromatography workstation designed to meet the data acquisition, analysis and file management needs of individual chemists or small laboratories. The workstation comprises the Hewlett Packard 9000 series 200 computer, a Winchester disk drive and the HP ThinkJet printer, together with Nelson's XtraChrom software and one of four intelligent A/D interfaces. Up to ten instruments, each interfaced to up to two detectors, may be controlled by this HP3362A or B chromatography data system. As well as standard gas and liquid chromatography applications, the system can be used for capillary GC, ion chromatography and amino-acid analysis.
Reader Service No. 120.



Waters Expert software for chromatography.

● The Waters Expert multi-instrument chromatography software gives the Waters 840 data and chromatography control station simultaneous HPLC, GPC, GC and ion chromatography data reduction, together with facilities for multi-instrument control. Expert software provides chromatography data acquisition from up to four chromatographs simultaneously, with each system acquiring data from up to four detectors. In addition, up to four Waters HPLC systems can be controlled from the keyboard of the Waters 840 data and chromatography control station. The efficient multi-tasking operating system of the Waters 840 allows the monitoring of a separation from up to four different detectors simultaneously on the CRT screen. In addition, the Waters 840 provides virtually unlimited networking capabilities, including ETHERNET compatibility for high-speed data transfer. An IEEE, RS-232 interface allows communication with additional 840 systems or other computers.
Reader Service No. 121.

● The Consort II computer interface system, designed and developed by ICI (Australia), forms the basis of a comprehensive Apple computer-based data station for chromatography. The instrument provides a three-in-one system for accurate data collection on two channels, dual pump control for HPLC and control of peripheral devices, such as autosamplers and fraction collectors. Consort II operates with either an Apple II+ or IIe computer in conjunction with a comprehensive software system called Appligration II designed by Dynamic Solutions Corporation of California. The system can be configured by the user to cope with a wide range of chromatographic data including capillary GC, with sampling rates adjustable from 0.05 Hz up to 200 Hz. A special package for gel permeation chromatography is included. The Consort II computer interface system is marketed in the UK by Biotech Instruments.
Reader Service No. 122.

● Designed for use with the ACT Apricot range of microcomputers, Dynatech's new ABO/Rhesus blood-grouping programs interpret results from the microtitre plate, whilst offering flexibility of plate format, accumulative records of groups performed, and storage space for full data on up to 750 full plates (7,500 patients per data disk). The program also allows for alteration of interpretation parameters which may be used to re-interpret raw data from memory without the need to re-read the plate. This new program, developed in conjunction with Sanguin Computing, operates on the Apricot PC and Xi microcomputers and also on the Sirius microcomputer. Also new from Dynatech is its MicroBank System for the full automation of the entire blood-grouping operation in microtitre plates. Composed of three different work stations, the MicroBank has been designed to maintain patient integrity and avoid incorrect grouping due to operator error.
Reader Service No. 123.

● The latest version of LABTECH NOTEBOOK, a sophisticated menu-driven software program for real-time data acquisition, control and analysis, now supports hardware devices from Action Instruments, Cyborg, Datel, IBM, Interactive Microware, Keithley DAS, and Tecmar. Equipment from Acrosystems, Burr Brown, Data Translation, Metrabyte and Taurus is already supported by this software. NOTEBOOK delivers full hardware functionality of every data acquisition device it supports. The latest version, LABTECH NOTEBOOK 2.5, provides support for real-time thermocouple linearization and compensation. Data may be collected as temperature points directly from standard thermocouple devices, without requiring linearizing data conditioners. LABTECH NOTEBOOK supports the IBM AT, and it can also be integrated with spreadsheets like Lotus 1-2-3.
Reader Service No. 124.

Software-controlled colour measurement from Pye Unicam.

● The latest software-controlled colour measurement system from Pye Unicam is based on the PU 8800 high-performance UV/visible spectrophotometer. The new system uses an integrating spheroid and a fast, powerful software package for the HP 85 computer and is the only non-dedicated system that completely conforms to the requirements of the CIE, the governing body of colour science. The PU 8800 range includes a video display, built-in recorder and printer options and a choice of side or end-window photomultipliers. Available on tape and disk, the software provides measurements of colour or colour difference in up to three modes — diffuse or total reflectance and transmission. Illuminants A, C, D_{65} and D_{75} are offered, together with an additional two illuminants of the user's choice.
Reader Service No. 125.

Mettler software kit for thermal analysis.

● The performance of the Mettler FP800 thermal analysis system can be substantially enhanced by connection to a computer. For this purpose Mettler offers a software kit, which has been specially designed for the Epson HX20 hand-held computer. In addition to controlling the unit, it also permits various standard applications to be called up, results to be calculated and data stored for later processing. At very little extra cost, the FP800 can also be adapted for special applications, so that it operates automatically in accordance with national and international standards (such as melting point of plastics according to ASTM, clear melting point of fats according to AOCS). The program is written in MICROSOFT BASIC, so that it can be adapted easily to the individual requirements of the user.

WAVELENGTH METERS

For Use With HIGH REPETITION RATE PULSED LASERS

Hovemere Ltd. (UK) announce a range of wavelength meter systems which measure the exact wavelength of a pulsed or continuous laser source with a wavelength precision of 1 part in 100,000,000 The instrument provides real-time wavelength measurements for each pulse at repetition rates of up to 30 pulses per sec.

The wavelength meter is based on an ultra-stable Fabry-Perot interferometer, and the instrument can be run from any of the IBM-PC range of personal computers, or strict compatibles. Data output (mean wavelength, spectral line profile, peak and/or total pulse intensity) are available within the PC memory, or can be transmitted via serial or parallel protocols to a second computer. This second computer may, for example, be the user's controller for the laser and detector system.

Laser detection systems are also available for the near UV to near infra-red spectral region. Software packages are available to run a complete laser, wavelength meter and detector system, from a single computer such as the IBM PC-AT, or COMPAQ DESK-PRO, or the DEC PDP-MICRO-11 family These software packages include graphical support for monitoring the performance of the laser, wavelength meter and detector, and for data analysis and storage/retrieval.

For extremely accurate wavelength measurement, over a limited absolute wavelength range, a single interferometer unit can be used A triple-unit system can monitor pulse by pulse laser spectral output variations (intensity/wavelength jitter) over an extended wavelength range, and provide absolute values of the wavelength

ROYAL HOLLOWAY AND BEDFORD COLLEGES

NEW BLOOD LECTURESHIP IN GEOPHYSICS

For research in the fields of seismic reflection processing, modelling and interpretation and to assist in teaching a new MSc course in Basin Evolution and Dynamics The new Geology Department will be based at Egham and is being created by the amalgamation of the Departments from Bedford, Chelsea and King's Colleges.

Salary scale £8,753 — £16,158 including London Allowance. Candidates must be under 35 years of age.

Please send a self addressed envelope for further details to: Mrs D J Odds, Personnel Officer, Royal Holloway and Bedford Colleges, Egham Hill, Egham, Surrey, TW20 0EX, to whom applications (two copies) with CV and the names and addresses of two referees should be sent. (6787)A

IMPERIAL CANCER RESEARCH FUND
Developmental Biology Unit
Oxford

RESEARCH SCIENTIST

Applications are invited for a five year appointment with the prospect of tenure Applicants should be specialists in any area of developmental biology, of senior postdoctoral status and able to plan and execute an independent research programme

The Unit which will open early in 1986 is situated in the Zoology Department of Oxford University. The Director is Prof R Gardner and permanent staff members are Drs D Ish-Horowicz and J Slack.

Salary range £11,675 to £14,925 (revision pending).

For furhter details write or telephone Ms S M Hurley, Imperial Cancer Research Fund, 44 Lincoln's Inn Fields, London WC2A 3PX on 01-242 0200 ext 305. Please quote reference 82/85 (6819)A

UNIVERSITY OF BRISTOL
DEPARTMENT OF PHYSIOLOGY

RESEARCH ASSISTANT

Applications are invited for a Research Assistant in the Department of Physiology supported by a grant from the British Heart Foundation to Professor R A Chapman

The post will be for 2 years initially and will be concerned with a study of the ionic basis of the Calcium Paradox of the heart

Candidates with a higher degree in Physiology or an allied subject are preferred for appointment on the 1A scale but those without a higher degree and hence eligible for a 1B post would also be considered.

The post will commence on the 1st October 1985 with a starting salary up to £8,540

Applications, with the names of 2 referees, should be sent to Professor R A Chapman, University of Bristol, Bristol, BS8 1TD by the 1st July (6814)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF IMMUNOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

required for screening of new monoclonal antibodies on the EPICS V fluorescence activated cell sorter, separation of cell populations from patients under antibody/cyclosporin-A therapy for functional assays, and assistance in investigating immune competence after organ transplantation

Salary range £7,520 — £12,150 (under review) plus £1,233 London Allowance, 5-year appointment

Further particulars available from the School Office, RFHSM, Rowland Hill Street, London, NW3 2PF (01-794 0500 Extn 4262) to which applications (full curriculum vitae and names and addresses of two referees) should be sent by 28 June 1985. Please quote ref IMM/PRA. (6823)A

MICROBIOLOGIST HEAD OF THE GROUP

We are one of the leading concerns with several billion DM overheads and offer an excellent opportunity for a highly qualified professional to continue our progress in development in the fields of soluble polymer and fatty biotechnology.

The applicant is expected to build up and form a newly group. The succesful candidate will have an excellent academic record, a PhD in microbiology as well as several years of experimental experience in genetics. He speaks English and German.

A competitive salary will be offered which will be commensurate with qualifications and experience. We offer excellent conditions of employment.

For further information please contact us or send your application including CV and names of two references to: (W1938)A

PERSONALBERATUNG Kaiserswerther Str. 115

Professor and Head

Department of Biochemistry

The University of Iowa College of Medicine is seeking to recruit a biochemist with a distinguished record of scholarship and original research to assume the position of Professor and Head of the Department of Biochemistry. Preferred candidates should have a record of high academic accomplishments and be committed to providing the scientific, educational and administrative leadership for the Department of Biochemistry.

PhD and/or MD degree, or equivalent, and a demonstrated scholar and leader in Biochemistry.

Appropriate for qualifications and responsibilities for a professor and Head of Biochemistry. Excellent fringe benefits.

The University of Iowa, Iowa City, IA 52242 is an Equal Opportunity Employer.

Interested persons are invited to direct inquiries and submit vitae to: Richard G. Lynch, MD, Department of Pathology, College of Medicine, University of Iowa, Iowa City, IA 52242.

(NW1837)A

International Institute for Aero-Space Survey and Earth Sciences,
350 Boulevard 1945, Enschede
The Netherlands. Tel. 053 - 32 03 30

ITC is concerned with international scientific education, research and consulting in aerial photography and teledetection, photogrammetry, aerospace survey application in landresources studies, agriculture, earth sciences, human settlements, geo-data processing and cartography, in particular directed towards the needs of developing countries.

The Institute undertakes scientific training at B.Sc., M.Sc. and Ph.D. levels in survey techniques especially for students from developing countries.

Most instruction at the Institute is given in the English language and includes both introductory and advanced courses in Soil Survey using Aerial Photography and other Remote Sensing techniques.

Applications are invited for the post of

professor in soil survey

charged with education and research in soil survey and its applications.
Capable of liaising with other earth- and agricultural sciences as well as with disciplines specializing in physical aspects of geo-data processing.
Applicants will preferably have a Ph.D. degree based on research in Soil Science, proven research ability. Experience in post graduate teaching and in Soil Survey, with emphasis on Soil- and landscape relationships and including the application of image interpretation, is required. Experience in developing countries is required. Leadership qualities are required.

(Further details about profile and task description will be sent to candidates in the form of the Structural Report on the Professorship in Soil Survey).

For further information you may contact Prof.dr.ir.K.J. Beek, Rector, telephone 053-320330, ext. 214.

Salary will be in accordance with the Netherlands Government scales. The gross salary ranges from *f* 6.364,- (minimum) to *f* 9.005,- (maximum) per month exclusive of allowances.

Written application and detailed curriculum vitae should be sent as soon as possible to the Head of Personnel Dept. of ITC, P.O. Box 6, 7500 AA Enschede (the Netherlands).

Information from third persons regarding suitable candidates will be considered.

(W1937)A

FACULTY OF VETERINARY MEDICINE
UNIVERSITY OF UTRECHT

The Faculty of Veterinary Medicine of the University of Utrecht, The Netherlands, invites applications for the position of

Full Professor in Cell Biology and Histology

Applicants are expected to meet the following requirements:
- expertise in cell biological and experimental histological research and research management;
- experience in teaching;
- willingness to collaborate with the other disciplines within the faculty;
- willingness to serve on faculty boards and committees.

Candidates should:
- possess a Ph.D. or equivalent academic degree;
- be specilized in cell biology and histology as evidenced by publications of high standard;
- be willing to learn Dutch within a reasonable period of time.

Further information is available on request.

The salary will be determined according to the experience of the applicant.

Applications, accompanied by a full curriculum vitae and a list of publications, or suggestions of suitable candidates, should be (confidentially) sent to:

J.J. van der Kaaden, Secretary of the Appointment Committee Professorship Veterinary Cell Biology and Histology, Faculty of Veterinary Medicine, P.O. Box 80.163, 3508 TD Utrecht, The Netherlands. no. 170.173.

(W1944)A

DEAN

College of Earth and Mineral Sciences
The Pennsylvania State University

Applications and nominations are invited for the position of Dean of the College of Earth and Mineral Sciences Candidates must possess an earned doctorate, scholarly/professional qualifications for a tenure professorship, and administrative experience and inter-personal skills needed to provide academic and organizational leadership.

The College of Earth and Mineral Sciences offers B S., M.S. and Ph.D. degree programs in six departments (geosciences, geography, mineral economics, meteorology, materials science and engineering, and mineral engineering), and has an outstanding reputation for both teaching and research

The Search Committee will begin to review résumés on July 1, 1985 and will continue to receive them until a candidate is selected.

Applications and nominations, accompanied by résumés and other supporting material, should be submitted to: Arnulf Muan, Chairman, EMS Dean Search Committee, 201 Old Main, University Park, PA 16802.

(The Pennsylvania State University is an Equal Opportunity/ Affirmative Action Employer). (NW1863)A

IMMUNOLOGY

The University of Pennsylvania has a tenure track position available in the field of viral immunology. This position is assigned to the Section of Viral Oncology, Department of Clinical Studies, New Bolton Center, the rural campus near Kennett Square

Duties will include research, teaching and service. Emphasis will be placed on the development of an active research program on the immunobiology of the bovine leukemia virus (BLV). This program may include studies on mechanisms of BLV-induced leukemogenesis at the host, cellular and molecular levels, including identification and characterization of the target cells for neoplastic transformation. Service responsibilities will include consulting in diagnostic immunology. Teaching will relate to graduate students as well as students of veterinary medicine. The appointee will be expected to assume a leadership role in the field of immunology on this campus.

Qualifications are a PhD degree or the equivalent and at least two years postgraduate experience in research. A DVM or MD degree would be an advantage. Experience in viral immunology and monoclonal antibody techniques would also be an advantage. Rank and salary will depend on qualification and experience. **Applications should include a curriculum vitae and the names of three referees. They should be addressed to Dr. Jorge F. Ferrer, Chief, Section of Viral Oncology, Department of Clinical Studies, School of Veterinary Medicine, University of Pennsylvania, Kennett Square, PA 19348.** *The University of Pennsylvania is an equal opportunity employer. Women and minorities are encouraged to apply.*

(NW1851)A

MEMBRANE TRANSPORT

Postdoctoral and advanced research assistant positions are available immediately for individuals interested in pursuing studies on the structure and mechanism of ion-translocating ATPases. The ATPase in the plasma membrane of *Neurospora* is an electrogenic proton pump that operates via a phosphoryl-enzyme intermediate identical to those of the animal cell transport ATPases. Research will involve investigations of the biochemistry and molecular biology of this ATPase with the goal of elucidating its molecular mechanism. Salaries are commensurate with experience. Send curriculum vitae and names of three references to. **Dr. Gene A. Scarborough, Department of Pharmacology, School of Medicine. University of North Carolina at Chapel Hill, Chapel Hill, N.C. 27514.**

Equal Opportunity Employer (NW1866)A

UNIVERSITY OF STOCKHOLM
Department of Zoology

ZOOECOLOGIST

Applications are invited for a position as "eo docent" (roughly equivalent to US assistant professor) primarily intended for a person with several years of post-doctoral research experience.

The position is open provided certain formal decisions are taken and it is advertised for a period of three years, but is usually renewed for another three year period. Starting salary L 18 (Swedish crowns 120 000 per annum = roughly 13 300 US$).

Docent is a research and teaching position, and requires a minimum of 75 hours of lecturing per annum or equivalent supervision of graduate student research, some administrative duties, and a vigorous research programme Applicants are selected primarily on the basis of their scientific publications, but teaching experience is also required.

Research is presently conducted mainly in the fields of evolutionary ecology (study objects insects and mammals) and marine and brackish water ecosystems and population ecology.

For further information contact: Professor H Ackefors, Department of Zoology, University of Stockholm, 106 91 Stockholm, Sweden (Telephone 00946-8164020).

Applications including Curriculum vitae plus one copy of published accepted and submitted papers, a short summary of the applicants research and teaching experience, names and addresses of three references and any other documents the applicant wishes to submit should be addressed to The Board of Stockholms University, Fredrik Bloms Hus, University of Stockholm, S-106 91 Stockholm, Sweden, and received no later than August 15, 1985. Quote reference number 338/85

(W1941)A

MOLECULAR BIOLOGIST

The Biology Department at the University of California, San Diego invites applications for a tenure-track position at the assistant professor level, salary range $25,500-$32,200. Applicants must have Ph.D. and should have a minimum of two years postdoctoral experience. The department is interested in applicants who have a commitment to applying molecular techniques to problems of the nervous system. The applicant will be expected to interact with an active group of neurobiologists and molecular biologists in the Biology Department. **Applicants should forward their Curriculum vitae with names of three references and selected reprints by July 15, 1985 to: Dr. A.I. Sleverston, Chairman, Search Committee, Dept. of Biology, B-022, University of California, San Diego, La Jolla, CA 92093.**

The University of California, San Diego is an Equal Opportunity/Affirmative Action Employer.

(NW1858)A

Faculty Positions in Developmental Biology

The Molecular Biology and Virology Program at the Sloan-Kettering Institute and the Sloan-Kettering Division of the Cornell University Graduate School of Medical Sciences is seeking to fill several tenure track positions in the area of prokaryotic and eukaryotic developmental biology. Individuals will be expected to establish independent research programs that utilize genetic and molecular approaches to the analysis of model pro- and eukaryotic organisms. **Applicants should submit their Curriculum Vitae, a brief statement of research accomplishments and goals and the names of three references to Dr. Ora M. Rosen, Sloan-Kettering Institute, 1275 York Avenue, New York, N.Y. 10021.** (NW1847)A

MOLECULAR VIROLOGIST

The University of Pennsylvania has a faculty position available in molecular virology. The position is in the Section of Viral Oncology, Department of Clinical Studies, New Bolton Center, the rural campus near Kennett Square.

Duties will include research, teaching and service. Emphasis will be placed on the development of a research program on the molecular biology of the bovine leukemia virus (BLV). The precise area of this program will be complementary to ongoing studies of the molecular mechanism of BLV-induced leukemogenesis and the regulation of viral transcription in BLV-infected and leukemic cells. Service responsibilities will include consulting in diagnostic virology. Teaching will relate to graduate students as well as students of veterinary medicine.

Qualifications are a PhD degree and at least two years postgraduate experience in research on molecular aspects of RNA tumor viruses. Further experience with recombinant DNA technology, gene cloning and sequencing, and gene expression in prokaryotic and eukaryotic systems would be an advantage. Rank and salary will depend on qualifications and experience. **Applications should include a curriculum vitae and the names of three referees. They should be addressed to Dr. Jorge F. Ferrer, Chief, Section of Viral Oncology, Department of Clinical Studies, School of Veterinary Medicine, University of Pennsylvania, Kennett Square, PA 19348.** *The University of Pennsylvania is an equal opportunity employer. Women and minorities are encouraged to apply.* (NW1852)A

CSIRO
AUSTRALIA
RESEARCH FELLOW BIOCHEMISTRY/ENZYMOLOGY
$A26,001 - $A38,243
DIVISION OF PROTEIN CHEMISTRY PARKVILLE VIC

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Protein Chemistry is a member of the Institute of Industrial Technology

GENERAL: The Division of Protein Chemistry, with a staff of 118, conducts scientific research on the structure and function of proteins and their production via biotechnology and synthetic routes. The Division is well equipped and has a wide range of facilities for biochemical and biotechnological research.

Located in Parkville, the Division is situated close to a major university and several related research facilities. Collaboration with scientists from other CSIRO laboratories will be encouraged.

The appointee will be a member of a program which has 12 professional scientists with expertise in the fields of protein chemistry and wool technology.

This position is funded by a two year grant from the Wool Research Trust Fund with the possibility of renewal for a further two years.

DUTIES: In collaboration with research scientists from this Division and in close association with scientists from the Divisions of Textile Industry and Chemical and Wood Technology, the appointee will undertake research into the potential use of enzymes in wool processing and effluent control. It is envisaged that enzymes will be isolated from various sources to carry out specific hydrolysis reactions of sterol esters and non-glyceride fatty acid esters for the hydrolysis of wool wax and for effluent treatment from scouring works. A parallel study will require the isolation of cellulose and lignin degrading enzymes suitable for the removal of vegetable matter contamination from processed wool.

In the event of suitable enzymes being isolated for either of the end uses, it is proposed that the genetic engineering facilities of this laboratory will be used to develop economic methods of production of the required enzymes.

QUALIFICATIONS: A PhD degree or equivalent qualifications in a relevant field and demonstrated research ability. Post-doctoral experience in enzymology or related fields would be an advantage.

TENURE: A term of 2 years, with the possibility of a further term of 2 years. Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No Y8789, should be directed to:

The Chief
CSIRO Division of Protein Chemistry
343 Royal Parade
PARVILLE VIC 3052
AUSTRALIA

FACULTY POSITIONS IN MOLECULAR BIOLOGY

The Molecular Biology and Virology Program at the Sloan-Kettering Institute and the Sloan-Kettering Division of the Cornell University Graduate School of Medical Sciences is seeking applications from molecular biologists for several tenure track faculty positions. The potential recruit should be using modern genetic, molecular biological and biochemical techniques to study problems in the general area of prokaryotic and eukaryotic cellular or viral gene expression and gene replication. The specific rank of appointment will be commensurate with the candidate's experience and achievements. This is a rapidly expanding program consisting of 20 independent faculty members with diverse research interests who are committed to basic research and the training of graduate students.

Please submit your Curriculum Vitae, present and future research plans and names of at least three referees to: Dr. Robert Krug or Dr. Jerard Hurwitz, Sloan-Kettering Institute, 1275 York Avenue, New York, NY 10021. (NW1846)A

APPLIED/ COMPUTATIONAL MATHEMATICIAN

$A26,001 - $A38,243

DIVISION OF MATHEMATICS AND STATISTICS ADELAIDE SA Australia

The Division of Mathematics and Statistics has a staff of 97, including 75 professional scientists. The Division's Headquarters are at Canberra, and there are Regional Offices located at Melbourne, Sydney, Adelaide, Brisbane and Perth Scientists of the Division provide advice on the statistical, mathematical and numerical aspects of research projects undertaken by scientists in other CSIRO Divisions, as well as conducting basic research in statistics and mathematics.

The Division has an active Applied and Computational Mathematics Program working on collaborative research projects with CSIRO Divisions in a variety of areas including manufacturing technology, oceanography, energy technology and applied physics. Members of the group are currently located in Canberra, Hobart, Melbourne and Sydney.

The successful applicant will be located in Adelaide and in addition to working on collaborative projects with Adelaide Divisions (including Soils and Manufacturing Technology) will be expected to contribute to the basis research of some aspect of applied and computational mathematics.

QUALIFICATIONS: A PhD degree or equivalent qualifications in a relevant branch of mathematics, together with a proven record of research and collaboration in relevant areas of mathematics. Expertise in the numerical solution of partial differential equations, numerical linear algebra and computational problem solving is particularly relevant. Familiarity with industrial applied mathematics and the mathematical modelling of the thermal processes is also desirable.

TENURE: The position is available for 3 years with the possibility of a further term. Australian Government superannuation benefits available

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two referees and quoting reference No A3499, should be directed to

The **Department of Biology, University of Saskatchewan** invites applications for a tenure-stream position at the **Assistant Professor** level in the area of the molecular genetics of plants.

Candidates should have a Ph.D. degree and, preferably, additional research experience in recombinant DNA techniques. Capability in the field of control of gene expression and plant genetic transformation is essential.

Send curriculum vitae and the names of at least three referees to **Dr. John King, Head, Department of Biology, University of Saskatchewan, Saskatoon, Sask., S7N 0WO, Canada by August 1, 1985.**

In accordance with Canadian immigration requirements this advertisement is directed to Canadian citizens and permanent residents. (NW1850)A

ICRISAT

International Crops Research Institute for the Semi-Arid Tropics (ICRISAT)

is seeking a

Principal Training Officer

at ICRISAT Sahelian Center, Niamey, Niger

To organize and conduct several levels of training in agriculturally-related subjects in West Africa for the benefit of scientists and technical support personnel of the National Agricultural Research Systems (NARS) of the region and related extension and action agencies. The Principal Training Officer must also evaluate on a recurring basis, the training and agriculturally-related education needs of West African NARS; aid in the identification of trainees and students for assignment to Training Programs conducted in West Africa and at ICRISAT Center, India; facilitate matters relating to the designation, assignment and travel, of all students and trainees from the West African region; and have responsibility for the housing, personal welfare and financial arrangements for all trainees and students assigned to ICRISAT in West Africa, develop over time an inventory of human resources available for agricultural research in the region and follow-up on trained personnel to measure impact of training program. The incumbent must also organize workshops, conferences and symposia and aid the research staff in the conduct of these activities.

Qualifications: Candidates must have an advanced degree (preferably PhD) in an agricultural discipline with formal training in educational subjects, five years experience in teaching agricultural subjects at various levels of student educational preparation, and some evidence of research accomplishment. A competence in French and English is essential. Most teaching and course materials will be in French The position will require an ability to travel frequently in the region. An initial orientation period of about 4 months at ICRISAT Center, India will be required. Salary for the position is at the principal staff level, according to qualifications and experience. The position is on a three year contractual basis with possibilities of further extension. The post is located at the ICRISAT Sahelian Center near Niamey, Niger, which is regional headquarters for ICRISAT's West African programs. Niamey, the capital city, has good living conditions, international airlines connections, and educational facilities for children in French and English.

Send résumé and names and addresses of three references within 30 days of the date of advertisement to Director General, ICRISAT, Patancheru P.O. Andhra Pradesh 502 324, India. (W1934)A

Sunderland & Teeside Polytechnics

NORTH EAST BIOTECHNOLOGY CENTRE

The North East Biotechnology Centre (NEBC) is a National Centre for Biotechnology based at Sunderland and Teesside Polytechnics The Centre has the following vacancies for research staff.

RESEARCH ASSISTANT

Applications are invited from honours graduates, or final year students expecting to graduate, in Microbiology/Biochemistry or related subjects to undertake research into the flocculation behaviour of *Bacillus* cells in liquid culture. The investigation will involve the use of chemostat cultures and also biochemical fractionation techniques for isolating and purifying cell surface polyelectrolytes. The research supervisor will be Dr Tony Abbott.

POSTDOCTORAL RESEARCH FELLOW

This post is open to candidates with a Ph.D. in microbial physiology or a related discipline, and those about to complete their Ph.D The research will be concerned with microbial synthesis of chiral compounds of industrial importance and will involve fermentation in addition to enzyme purification and characterisation techniques. The principal research supervisor will be Dr John Colby.

An application form and further particulars may be obtained from the Personnel Officer, Sunderland Polytechnic, Langham Tower, Ryhope Road, Sunderland, SR2 7EE or telephone (0783) 76231 Ext 11.

Closing date: 27 June 1985 (6792)A

BRISTOL POLYTECHNIC

£8,500-£14,000 **South Bucks**

Amersham International, a highly successful British Company, is a market leader producing a wide range of high technology products for life science research, medicine and industry.

Our New Technologies Department is playing an increasingly important role in the development of the Division's business strategy through the innovation and development of immunological and molecular biology techniques at the very forefront of this fast moving area.

The department is currently addressing the need for systems and reagents for DNA cloning, gene expression, nick translation, non-radioactive labelling, hybridisation, the requirements of biotechnology and the production of anti-bodies and enzyme systems for cell biology and Pathology.

As a result of continuing expansion we now have an exciting career opportunity for a development scientist to evaluate and develop a broad range of tissue processing and staining techniques for localisation of biological molecules.

Qualified to at least first degree level in a relevant discipline, you should have both practical and theoretical knowledge of tissue processing and staining. The aptitude/ability to run projects with the minimum of supervision and work to tight deadlines is essential. Your flexibility will allow you to work with scientists of several different disciplines and to apply your knowledge in a number of new fields.

Salary in the range indicated will reflect qualifications and experience and will be enhanced by a benefits package including a generous pension scheme, 25 days' annual holiday and assistance with relocation, where appropriate.

Please write enclosing a CV, detailing your career to date, to Simon Voake at the address below.

Alternatively, please telephone Little Chalfont (02404) 4488, ext. 3569 for an application form. (6829)A

CHIEF TECHNICIAN

A chief technician is required to co-ordinate and supervise our growing central molecular biology facilities. Duties will combine both administrative and technical responsibilities. The successful candidate will be expected to play an active role in the experinmental work of the molecular medicine research group.

Applicants should have at least ten years laboratory experience of which at least five should have been spent in the molecular biology field. Previous administrative experience is essential.

Salary will be within the range £9,987 — £11,489 inclusive, depending on experience. Informal enquiries may be made to Dr James Scott, Head of the Molecular Medicine Research Group — Telephone 01-864 5311 extn. 2479. Application forms and job description may be obtained by writing to Miss B.A. Shaw, Personnel Dept. Quoting Reference 111/2/4275.

Closing date for applications 4 July 1985. (6781)A

PLANT GENE TECHNOLOGY and DNA RESEARCH

POSTDOCTORAL POSITION

Candidates with a background in plant physiology and/or DNA research are invited to join an industry-funded independent research group at the Institute of Molecular Biology of the Austrian Academy of Sciences in Salzburg.

We offer a salary and benefits commensurate with experience according to Austrian Academy of Sciences scheme. The initial appointment will be for one year with possible extention up to four years. **Résumé, list of publications and three letters of reference should be submitted to CHEMIE LINZ AG, Personalwirtschaft, POB 296, A 4021 Linz, Austria.**

CHEMIE LINZ AG (W1939)A

DRUG DESIGN SCIENTIST

G.D. Searle is a major international pharmaceutical company whose Research & Development Division at High Wycombe is involved with the discovery of new chemical and biological entities.

The Division is expanding its Drug Design and Computer Graphics expertise in line with other developments in its Medicinal Chemistry Department. There is now a vacancy for a scientist with interests and experience which lie in one or more of the following areas:-

- **Computational Chemistry and its application to drug design problems.**
- **Analysis of Structure-Activity Relationships using regression, classification and multivariate techniques.**
- **Physical Chemistry measurements (FT-nmr, FT-ir, pKa, logP) and their use in drug design.**
- **Software development in computational chemistry.**

The Drug Design group contributes in a major way to Medicinal Chemistry research programmes and also supports Protein Engineering and Molecular Genetics research. Software currently in use includes Chemlab and Chemgraf running on a VAX cluster

The Company offers competitive salaries, 23 days holiday, contributory pension fund, health insurance scheme, subsidised cafeteria, recreation club and modern offices in a very pleasant location. Generous relocation assistance will be available in appropriate cases

Please apply to the Personnel Manager, Searle Research & Development, Lane End Road, Sands, High Wycombe, Bucks. (Tel: High Wycombe 21124, Ext. 3372). Please quote reference CH157.

SEARLE

CHAIRPERSON

Department of Physiology and Biophysics

THE UNIVERSITY OF TEXAS MEDICAL BRANCH AT GALVESTON

Applications and nominations are invited for the position of Chairperson of the Department of Physiology and Biophysics. Candidates must be a highly qualified individual with nationally recognized credentials in research and senior academic accomplishments with administrative experience or potential. The position offers excellent opportunity to develop an internationally leading adademic department due to outstanding resources, scientific environment and faculty positions.

Application or nomination should include a curriculum vitae. Address correspondence to: James C. Thompson, M.D., Chairman, Department of Surgery, The University of Texas Medical Branch, Galveston, Texas 77550.

The University of Texas Medical Branch is an Affirmative Action/Equal Opportunity employer. (NW1856)A

Several positions are available at Geo. J. Ball, a major horticultural company in northern Illinois. The positions and qualifications are:

1 Plant Tissue Culture: 4 positions; PhD, MS or BS with single or combined background and experience in any of the following areas:

a. *in vitro* micropropagation
b. acclimation of tissue cultured plants *in vivo*
c. product system development in tissue culture
d. plant pathology
e. plant physiology
f. cell culture

2. Greenhouse Manager: BS preferred with experience in laboratory micropropagation.

Send résumé to:

Ball

Vice President -
Research & New Project Development
Geo. J. Ball, Inc.
P.O. Box 335
West Chicago, IL 60185

EQUAL OPPORTUNITY EMPLOYER

(NW1865)A

Postdoctoral Positions in

MOLECULAR VIROLOGY

Postdoctoral positions available in July to study molecular details of replication and gene expression in plant viruses and to construct gene vectors. Molecular biology and/or recombinant DNA experience desirable.

Send curriculum vitae and three letters of reference to: **Dr. Paul Ahlquist, Biophysics Laboratory, University of Wisconsin, Madison, WI 53706 USA.** An equal opportunity employer.

(NW1838)A

FACULTY POSITION - ENVIRONMENTAL TOXICOLOGY

The Department of Environmental Health Sciences of the School of Public Health, University of Alabama at Birmingham (UAB) is seeking an assistant or associate professor in environmental toxicology. This is a tenure-track position with responsibilities that include teaching of graduate level toxicology courses and initiation of independent and collaborative research. A doctorate in toxicology and an interest in carcinogenesis neurotoxicology, or inhalation toxicology, will be shown preference. Salary is negotiable, depending on qualifications. Curriculum vitae and names of three references should be sent before 30 June 1985 to: **Dr. Robert G. Meeks, Chairman, Search Committee, Department of Environmental Health Sciences, School of Public Health, University of Alabama at Birmingham, University Station, Birmingham, Alabama 35294.** *An Equal Opportunity/Affirmative Action Employer.*

(NW1859)A

WASHINGTON, DC

Immediate and Fall Post-Doctoral Research Positions. Past Interest and knowledge of the Molecular Biology of the nucleus desirable. To combine gene cloning and chromatin biochemistry to study Poly (ADP-ribosylation) involving replication, gene expression and nuclear oncogene proteins. Collaboration with leading labs at NIH.

Send curriculum vitae, reprints and names of three references to: Dr. Mark Smulson, Dept. of Biochemistry, Georgetown Univ. Schl. of Medicine, Washington, DC 20007.

(NW1853)A

RESEARCH ASSISTANT

Immediately available in protein chemistry. Qualified applicants should have BS or MS in chemistry or biochemistry. Experience with protein purfication and analytical instrumentation (HPLC, protein sequencer is preferred.

Send cv and 3 letters of reference to Personnel Manager, W. Alton Jones, Cell Science Center, 10 Old Barn Road, Lake Placid, New York 12946 refer to job order — CR-8506. (NW1845)A

POSTDOCTORAL POSITIONS

Two postdoctoral positions available August 1, 1985 for studies of the mechanisms of senescence of differentiated cells in culture and mechanisms of immortalization in neoplastic transformation. PhD or MD required with training in cell and molecular biology

Send curriculum vitae and the names of two references to Dr. Peter J. Hornsby, Department of Cell and Molecular Biology, Medical College of Georgia, Augusta, Georgia 30912. EOE/AAP J2900. (NW1842)A

POSTDOCTORAL POSITION

Recently formed multidisciplinary group with stable long-term funding seeks PhD or MD to participate in studies of the role of DNA topoisomerase in tumor biology and cancer chemotherapy. Investigations at the molecular/cellular level will be coordinated with those examining the basis for tumor responsiveness to established and newly synthesized topoisomerase-mediated anticancer drugs. Salary negotiable.

Send curriculum vitae, three reference, and brief statement of research interests and experience to: Warren Ross, MD, or Tom Rowe, PhD Box J-267, JHMHC, University of Florida, Gainesville, Fla. 32610.

(NW1843)A

Boehringer Ingelheim

Research Opportunities in the Field of CNS Pharmacology

for a PHYSICIAN, BIOLOGIST or BIOCHEMIST in WEST GERMANY

The Boehringer Ingelheim Company is an internationally oriented pharmaceutical company with a range of pharmaceuticals originating largely from its own research and development.

For our C N S Research Group we are looking for an enthusiastic scientist with a strong experimental background in physiology, biochemistry or pharmacology.

It is our aim to identify new therapeutic principles. We are seeking to achieve this goal through interdisciplinary research in chemistry, biochemistry, molecular biology and genetic engineering.

Special knowledge in the areas of biochemical psychopharmacology or electrophysiology would be of considerable benefit.

For further information please contact Professor Jennewein Tel. 06132/77-2135.

Applicants should send their full C.V. to

Boehringer Ingelheim KG, Personalabteilung
D-6507 Ingelheim am Rhein/West Germany (W1950)A

BIOTECHNOLOGISTS!

What's going on in the world's fastest-growing scientific discipline?

Paul Siman, Bio/Technology, 65 Bleecker St., New York, NY 10012.

PHILIPPS-UNIVERSITÄT MARBURG

Im Fachbereich Humanmedizin am Institut für Normale und Pathologische Physiologie ist eine

Professur (C4)

für Physiologie

zu besetzen. Der Bewerber soll das Gesamtfach Physiologie in der Lehre vertreten Können und wissenschaftlich international ausgewiesen sein.

Fur die Ernennung zum Professor sind grundsatzlich padagogische Eignung und — als Nachweis der Befähigung zu wissenshaftlicher Arbeit — neben der Promotion die Habilitation oder gleichwertige wissenschaftliche Leistungen erforderlich. Im übringen gelten die Einstellungsvoraussetzungen des § 39 a Hug.

Bewerbungen mit den ublichen Unterlagen (das Schriftenverzeichnis ist nach Originalarbeiten, Übersichtsartikel und Fallstudien zu gliedern. Bei gemeinschaftlichen Veroffentlichungen soll der Bewerber ausführen, worin seine Miturheberschaft besteht) sind bis zum *19.7.1985* zu richten, an den *Präsidenten der Philipps-Universität Marburg, Biegenstraße 10, D 3550 Marburg.* (W1930)A

CSIRO
AUSTRALIA
RESEARCH FELLOW
$A26,001 - $A38,243
DIVISION OF ATMOSPHERIC RESEARCH
ASPENDALE VIC

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists The Organization's research activities are grouped into five Institutes Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Atmospheric Research is a Member of the Institute of Physical Sciences.

GENERAL: The Division of Atmospheric Research has a staff of 130 including 70 professional scientists and undertakes research into physical and chemical aspects of atmospheric phenomena and related areas. The Clouds and Radiation Program in the Division is concerned with aircraft, lidar and satellite observation of various atmospheric and surface characteristics as well as related theoretical studies of clouds (in particular) as they control the energy input to the earth's atmosphere system Particular emphasis at this time is on satellite observations using the new CSIDA facility for satellite reception and data analysis

DUTIES. Although there will be considerable freedom to pursue the appointee's own ideas, he/she will conduct research in one or both of two related areas.

(a) use of satellite radiance data to abstract real information on atmospheric and surface phenomena and

(b) use of various lidar techniques for analysis of upper level clouds and aerosols

The appointee will be expected to relate the work to the general problem of climate modelling and address such questions as the radiative control of deserts and drought

QUALIFICATIONS· A PhD degree or equivalent qualifications in a related field and strong evidence of independent research ability

TENURE. A term of three years, with the possibility of a further term of 2 years Australian Government superannuation benefits available

APPLICATIONS. Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A1827, should be directed to·

The Chief
CSIRO Division of Atmospheric Research

(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW,
MIDDLESEX, HA1 3UJ

POST DOCTORAL FELLOW IN MOLECULAR BIOLOGY

Applications are invited from science graduates for a 3 year postdoctoral position in the Molecular Medicine Research Group to work on the molecular basis of atherosclerosis. The work will be particularly concerned with growth factor and apolipoprotein genes A minimum of 3 years experience in molecular biology is essential.

Salary scales are related to those for university non-clinical academic staff and salary on appointment will depend on age and experience Informal enquiries may be made to Dr James Scott (Head of Group) on 01-864 5311 Extn 2257.

Application forms and further details may be obtained by writing to Miss B.A. Shaw, Personnel Section quoting reference 111/1/4267.

Closing date for application 4th July 1985. (6780)A

UNIVERSITY OF ZIMBABWE
DEPARTMENT OF PHYSICS
(2 posts)

LECTURESHIPS/SENIOR LECTURESHIPS/ ASSOCIATE PROFESSORSHIP

Post A: Applicants should have a BSc Honours degree in Physics but preferably a PhD. The successful candidate is expected to teach at both undergraduate and postgraduate levels, as well as supervise MPhil and DPhil students in relevant research area

Post B. Applicants should have a BSc Honours degree in Physics but preferably PhD The successful candidate must be competent to teach Electronics to BSc undergraduates as well as supervise postgraduate research in Electronics Preference will be given to a candidate with some proven industrial experience.

Salary scales: Lecturer: Z$11,880 -Z$20,076, Senior Lecturer. Z$20,580 - Z$23,400, Associate Professor: Z$21,084 - Z$23,904 (including allowance).

Appointment on the above scales according to qualifications and experience.

Conditions of Service: Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on short-term contract basis with an initial period of two years Short-term contracts may, in exceptional cases, be extended.

Six copies of applications giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees should be addressed to the Director, Appointments and Personnel, University of Zimbabwe, P O Box MP 167, Mount Pleasant, Harare, Zimbabwe (Telex: 4-152 ZW). Candidates in the UK should also send an additional copy to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may be obtained

Closing date for receipt of applications is 12 July 1985.

(W1943)A

POSTDOCTORAL RESEARCH ASSOCIATE

A 2-year position is offered to study the effects of recombinant tumour necrosis factor in vivo and in vitro.

Potential areas of research include therapy in murine models, regulation of tumour cell sensitivity and regulation of tumour necrosis factor activity. Applicants should have a Ph D with experience in cellular immunology and biochemistry.

Send curriculum vitae and brief summary of research experience to German Cancer Research Centre (DKFZ), Im Neuenheimer Feld 280, D-6900 Heidelberg, FRG. (W1932)A

THE UNIVERSITY OF WESTERN AUSTRALIA
Perth
DEPARTMENT OF SURGERY

RESEARCH OFFICER/RESEARCH FELLOW

Applications are invited fro scientists who have completed a Phl degree in experimental anatomy c pathology, for a post-doctora fellowship in experimental opthalm pathology, in particular related to th neuro-anatomy of the macula Funding will be guaranteed for thre years in the first instance bu applicants should consider it as a opportunity to establish their ow laboratory and develop a long-ter career as a principal investigator Th Opthalmic Research Unit, Depar ment of Surgery, University c Western Australia is currentl relocating into the Lions Ey Institute, Queen Elizabeth II Medica Centre This facility consists of 6 modernised laboratories and office which will provide a unique mix c patient care, animal studies and basi research laboratories all in the sam geographic area. The unit ha extensive interests in retinal an vitreous disease and has active labor atories based on neurophysiology biochemistry and cell culture. Th successful applicant will collaborat closely with the Head of the Uni Professor Ian Constable, on anima and human studies of the macula an also with Associate Professor Joh Papadimitriou, Head of Departmen of Pathology, University of Wester Australia on new technology relevan to electron microscopic analysis o macular disease. Enquiries fo further information should b directed to Professor Constable a (09) 325:0101, extension 2822.

Current salary ranges: Researcl Officer — $A20,003 - $A28,306 pe annum; Research Fellow - $A26,236 $A34,467 per annum. Benefit include fares to Perth for self an dependent spouse Conditions o appointment will be specified in an offer of appointment which may b made as a result of this advertise ment

Applications in duplicate statin full personal particulars, qualifi cations and experience and the name and addresses of three referee should reach the Staffing Officer University of Western Australia Nedlands, Western Australia 6009 by 31st July 1985 (W1929)A

FERMENTATION RESEARCH

John & E Sturge Limited, a member of the RTZ Chemicals Group, wish to appoint a person to participate in an ongoing programme of fermentation research for processes for the production of organic acids, enzymes and other products. The work will be conducted in our Research Department, on the site containing our large scale fermentation facilities in Selby, Yorkshire, where citric acid and enzymes are currently produced.

The successful applicant will have obtained at least a 2 i) Honours Degree in microbiology or a related discipline, and would preferably have academic or industrial post-graduate experience in microbial physiology. The person appointed will be paid a salary commensurate with his/her qualifications and the responsibilities of the post. Assistance with relocation will be given in appropriate cases.

Sturge Biochemicals a member of the RTZ Group

Please send a detailed c.v. to Dr. W.J.E. Gardner, John and E. Sturge Ltd., Denison Road, SELBY, North Yorkshire, YO8 8EF. Previous applicants need not re-apply. 6698)A

The W. Alton Jones Cell Science Center
invites applications for the position of

Assistant Scientist

in the protein chemistry laboratory. Candidates should be willing to collaborate closely with the recombinant DNA laboratory and with several tissue culture laboratories that are engaged in the isolation, characterization and modification of bioeffectors produced by various differentiated cell types.

Expertise in modern microtechniques of protein sequencing is expected. Synthetic peptides will be used for structure-function studies in cell cultures and for raising antibodies.

Applicants should send curriculum vitae and references to: Personnel Manager. W. Alton, Jones Cell Science Center, 10 Old Barn Road, Lake Placid, New York 12946. (NW1844)A

The Waksman Institute of Microbiology, the Department of Chemistry, and the Department of Biochemical Engineering of Rutgers, The State University of New Jersey, invite applications and nominations for senior professorial positions in

PROTEIN ENGINEERING
PROTEIN CHEMISTRY
MACROMOLECULAR CRYSTALLOGRAPHY

at the Institute on the New Brunswick/Piscataway campus.

The successful candidates will join a multidisciplinary and rapidly expanding group of investigators in the study of biomolecular structure, function, and design. We seek distinguished leaders with demonstrated ability and commitment to conduct vigorous research programs, to interface with molecular biology, to teach at the graduate level, and to assume other usual academic responsibilities. Because of the interface with molecular biology, two of the positions, protein engineering and protein chemistry, will be associated with a curatorship of two resource facilities, the fermentation laboratory, F1, and the biomolecular instrumentation laboratory, F2. F1 will be equipped with new microprocessor controlled vessels and state-of-the-art analytical equipment. F2 will run and maintain an oligonucleotide synthesizer, a peptide synthesizer, an amino acid analyzer, a high resolution protein sequenator, and HPLCs. Access to the supercomputer at the newly established John von Neumann Center for Scientific Computing, to several VAX computer systems, and to computer graphics equipment provides excellent computational facilities for this program. Salary and rank will be commensurate with experience, background and professional qualifications.

Applications must include an expression of interest in the position, and up-to-date publication list, a *curriculum vitae,* and confidential letters of recommendation from five professional references. Applications will be accepted until the position is filled.

Applications and nominations may be directed to:

Professors Joachim Messing and Wilma K. Olson
Chairpersons
Biomolecular Structure
Program Search Committee
Waksman Institute of Microbiology
Rutgers, The State University
PO Box 759, Piscataway, New Jersey 08854-0759

(NW1849)A

Nous sommes un important groupe pharmaceutique international et en expansion.
Pour faire face à l'extension de ses objectifs, notre R. & D., située à Braine l'Alleud près de Bruxelles, recherche 3 collaborateurs ou collaboratrices de haut niveau:

UN(E) BIOCHIMISTE (senior)
UN(E) PHARMACOLOGUE (généraliste)
UN(E) NEURO-PHARMACOLOGUE (physiologie et comportement)

Ils sont appelés à animer et diriger une ou plusieurs équipes de recherche et d'évaluation de produits nouveaux ainsi que des projets de recherche impliquant des contacts multidisciplinaires internes et externes.

Les candidats recherchés doivent être porteurs d'un diplôme de Doctorat en Sciences ou équivalent; une expérience confirmée de plusieurs années dans la spécialisation indiquée est requise.

La connaissance courante du français et de l'anglais est requise.

Les candidatures, accompagnées de C.V., sont à adresser à:
UCB s.A. - Direction du Personnel/Développement
326 Avenue Louise-Bte 7 - B-1050 BRUXELLES

(W1949)A

FACULTY POSITION IN IMMUNOPHARMACOLOGY

The School of Pharmacy, University of California at San Francisco seeks an outstanding scientist for a tenure track position at the Assistant or beginning Associate Professor level in the Department of Pharmacy. We are particularly interested in an individual whose research interests will complement the Departmental strengths in drug delivery and pharmacodynamics. Specific areas of interest might include immunomodulation for therapeutic purposes, drug targeting by antibodies, the development of immunologic therapeutic agents, the development of immunologic indicies to monitor drug efficacy and toxicity of the formulation of mathematical models of the immune system.

Applicants should have a Ph.D., M.D. or M.D./Ph.D. and be committed to develop or continue a first-rate active research program. Teaching responsibilities will be in the professional and graduate curriculum.

Applicants should submit curriculum vitae, three letters of reference, and a statement on present and future research interests by August 15, 1985 to: Dr. Francis C. Szoka, Jr., School of Pharmacy, 926-8 University of California, San Francisco, CA 94143. ***UCSF is an Equal Opportunity/Affirmative Action Employer. Women and minorities are encouraged to apply***

UNIVERSITY OF GUELPH

COLLEGE OF BIOLOGICAL SCIENCE

Pre- and post-doctoral positions available for training in the Molecular Biology of post transcriptional control with special emphasis on structure and function of mRNP complexes and biogenesis of ribosome particles in procaryotic and eucaryotic systems Studies of this laboratory are directed to examining molecular events which occur during changes in growth rate and differentiation. Teaching opportunities available. Stipends for post-doctoral fellows are $17,500 to $21,000 and according to departmental guidelines for pre-doctoral fellows.

Please send résumé and names of three referees to:

Bruce H. Sells
College of Biological Science
University of Guelph
Guelph, Ontario
Canada N1G 2W1

(NW1848)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

SENIOR RESEARCH ASSISTANT

Applications are invited for the above postdoctoral position to work on the molecular biology of the expression of mammalian proteinases. The project is specifically concerned with the regulation of genes coding for kidney brush border endopeptidases. This post is funded by an SERC grant awarded to Dr R J Beynon and Dr P C Turner and is tenable for up to three years. Further information on the project may be obtained from Dr Beynon or Dr Turner on 051-709 6022, ext 2757 or 3183.

Initial salary within range £7,520 — £8,450 per annum (under review). The starting date is nominally 1 October, but may be open to negotiation for an outstanding applicant. Applicants should preferably be experienced either in protein chemistry/enzymology or gene manipulation

Applications, together with the names of three referees, should be received not later than 27 June, 1985 by the Registrar, The University PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/298/N.

(6701)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

DEPARTMENT OF SURGERY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post, supported by the Wellcome Trust, for three years The project is to study proteins of the endoplasmic reticulum membrane involved in intracellular transport and recognition, and will involve photoaffinity labelling, isolation of membrane receptor proteins, in vitro transcription/translation and preparation of DNA probes. Experience with membrane protein isolation or molecular biology would be an advantage, and the applicant should possess or expect to obtain shortly a PhD in biochemistry or related discipline.

Salary is on the IA scale for Research and Analogous Staff, with London Weighting, according to age and experience.

Applications including a curriculum vitae and the names and addresses of two referees should be sent to Dr B M Austen, Department of Surgery, St George's Hospital Medical School, Cranmer Terrace, Tooting, London SW17 0RE (Tel 672 1255 Ext 5150) Closing date 4 July 1985.(6809)A

MIDLAND CENTRE FOR NEUROSURGERY AND NEUROLOGY

DEPARTMENT OF PATHOLOGY

BIOCHEMIST IN CHARGE OF MUSCLE LABORATORY

(Senior/Principal Grade)

required on a locum basis (available grading up to Principal as defined by Whitley Council PTA regulations). The muscle laboratory is part of the Clinical Biochemistry Department but has close links with other sections (Electron Microscopy, Histopathology etc) as part of a comprehensive diagnostic service in muscle, central and peripheral nervous system pathlogy, to Hospital and Region. Clinical Biochemistry is a well-housed department, with nine staff at present, including five graduate scientists, one of whom is mainly engaged on muscle chemistry. Equipment includes two Ultra centrifuges, isotope counting facilities, fluorimeter and a spark camera for autoradiography. The successful candidate will be requried to continue and develop a diagnostic biochemistry service for the investigation of human metabolic muscle disease. Collaboration with current research projects will be expected, and there is an excellent opportunity to develop a personal research programme with the readily available material

Intending applicants are welcome to visit by appointment with Mr R A Westhead, (Principal Biochemist) 021-558 3232, ext 257.

Job description and application forms from: The Administrator, The Midland Centre for Neurosurgery and Neurology, Holly Lane, Smethwick, Warley, West Midlands B67 7JX.

Tel: 021-558 3232, ext 251.

UNIVERSITY OF NOTTINGHAM
Medical School

DEPARTMENT OF COMMUNITY HEALTH

TEMPORARY LECTURER OR RESEARCH FELLOW IN BEHAVIOURAL SCIENCE/HEALTH EDUCATION

A two year position of Temporary Lecturer or Research Fellow, with possible extension, is offered to undertake research on the development and implementation of an interactive computer based system of health risk appraisal for use in health assessment and education. Candidates should have expertise in the conduct of evaluative studies, and interests in health education, epidemiology, and disease prevention. Salary on the appropriate scale.

Potential applicants wishing to discuss the position or to receive further information and application forms should write to, or telephone, Professor J M Elwood, Department of Community Health, Queen's Medical Centre, Nottingham NG7 2UH; telephone 0602 700111, ext 3561. Closing date for applications 12th July 1985. (6778)A

UNIVERSITY OF SURREY

DEPARTMENT OF BIOCHEMISTRY

RESEARCH OFFICER

Applications are invited for two pos of Research Officer which a available imnmediately in th Department of Biochemistry. Fo both posts, applicants must have good degree in biochemistry or related subject.

Post 1 The Research Officer wi work with Mr B A Morris, Dr M Clifford and Dr B J Gould on a foo analysis project funded by th Ministry of Agriculture, Fisheri and Food. The objective is to develo an immunological method of analys capable of supporting legislation th controls which enzyme preparatio may be used as food additives. Th project should provide a challenge relently qualified young scientis interested in applying their skills this relatively new field. Previo experience in protein separatio immunoassay, especially ELISA, a knowledge of food manufacturi processes would be an advantag Further details of the post may b obtained from Mr Morris on 048 571281 ext 823 or Dr Clifford on e 435. Salary up to £7,520 per annu depending on age, qualifications an experience.

Post 2 A Research Officer required to work on a project funde by the Water Research Centre. Th project involves the production antibodies to pesticides and oth pollutants and the development non-isotopic immunoassay tec niques appropriate to the Wat Industry. Further details of the po may be obtained from Dr W Aher on 0483 571281 ext 497. Salary up £7,980 per annum depending on ag qualifications and experience.

Both posts are available for period of two years.

Applications in the form of curriculum vitae (3 copies) an including the names and addresses two referees, should be sent to th Personnel Office (JLG), Universi of Surrey, Guildford, Surrey, GU 5XH by 24th June 1985 quotin reference 398/N. Previous applican need not reapply. (6793)A

Applications are invited for the post of

LECTURER IN PHYSIOLOGY

The Department is particular seeking a physiologist who is veterinary graduate. It woul however, also be interested receiving applications fro candidates with a medical degree o research interest in cardiac musc The salary will be within the ran £7,520 - £14,925 per annum togeth with superannuation.

Applications including the nam and addresses of two referees, shou be sent by 28th June 1985, to t Registrar and Secretary, Universi of Bristol, Senate House, Bristol B 1TH, from whom further particula may be obtained. Please quote ref ence TLJ (6772)A

THE UNIVERSITY OF THE SOUTH PACIFIC

LECTURER I/SENIOR LECTURER IN ANIMAL SCIENCE — Post 85/33

Applications are invited for the above post in the School of Agriculture located at the Alafua Campus in Western Samoa. The appointee will take charge and direct the work of the Animal Science section of the School and will be responsible for the co-ordination of the teaching and research of two other members of the lecturing staff who jointly offer courses in animal science to students reading for the Diploma in Tropical Agriculture, the Bachelor of Agriculture and the Master of Agriculture by research. He will in addition be responsible for operation and further development of the School's livestock enterprises for demonstration, research and commercial purposes. Applicants should possess a first degree in Agriculture, Animal Science or Veterinary Science with postgraduate qualifications, preferably at doctoral level, in a relevant field of animal science. Research interests in the field of reproductive physiology would complement those of the present staff and meet the needs of the region for improvements in this area.

Salary will be in accordance with qualifications and experience in the Lecturer I scale: F$13,921-18,919 or Senior Lecturer scale: F$19,525-22,815 (£1 = F$1.48 on 28/5/5). In addition the University provides gratuity amounting to 15% of basic salary, appointment allowance and, subject to the University's current housing policy partly furnished accomodation at a rental of 12½% of salary. The University will contribute a sum equivalent to 10% of the appointee's salary towards his superannuation obligations. Appointment will be for a contract period of three years and may be renewable by mutual agreement. Candidates should send three copies of their curriculum vitae with full personal particulars, names and addresses of three referees and date of availability, to the Secretary, The University of the South Pacific School of Agriculture, Alafua Campus, PO Box 890, Apia, Western Samoa, to reach him no later than 19 July 1985. Candidates in UK should also send an additional copy to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1935)A

RESEARCH POSITIONS

1) Postdoctoral Associate and 2) Research Assistant (BS or MS) positions available in a research group working with RIBOSOMAL PROTEIN GENES AND cDNA EXPRESSION LIBRARY from higher plants. DNA cloning and/or sequencing experience required. Write to: Dr Alap Subramanian, Group Leader, Max-Planck-Institut fur Molekulare Genetik, Abt Wittmann, Ihnestr 63, Berlin-Dahlem, Fed Rep Germany. (W1933)A

THE NATURE CONSERVANCY COUNCIL

HIGHER SCIENTIFIC OFFICERS

3 contract posts with a duration of up to 2 years in the Geological Conservation Review Unit.

Applications are invited from specialists in the following subjects:

1 Vertebrate Palaeontologist (fish)

2 Palaeobotanist/Westphalian Stratigrapher

3 Pleistocene River Terrace Stratigrapher

The successful candidates will be required to undertake the assessment, selection and documentation of key earth science sites.

Qualifications and experience. Applicants should have a first or second class honours degree in an earth science, with at least three years PhD experience in the specified discipline. Candidates should also have undertaken relevant post-doctoral research and have experience in conservation. A current driving licence is essential.

Salary, depending on qualifications and experience. £7,435 rising to £10,039 per annum.

The posts will initially be based in Newbury but will be moved to Peterborough in 1986.

For an application form and further particulars please contact Miss B A Meredith, Personnel I, Nature Conservancy Council, Northminster House, Peterborough, PE1 1UA. Closing date for receipt of completed forms is 10 July 1985.

The Nature Conservancy Council is an equal opportunity employer. (6801)A

UNIVERSITY OF KEELE

DEPARTMENT OF BIOLOGICAL SCIENCES

DEMONSTRATORSHIPS IN ZOOLOGY AND BIOCHEMISTRY

Applications are invited from individuals with some research and, ideally, teaching experience for the posts of Demonstrator, initially for one year from October 1985, at a salary of £6,600 per annum, together with membership of the USS. For the Demonstratorship in Zoology, candidates should have a good degree in zoology or biological science. Applicants with interests in helminthology (especially the biology of metacestodes) or behavioural endocrinology will be given preference, but other areas are not excluded. For the Demonstratorship in Biochemistry, candidates should have a good degree in biochemistry or cell biology and should be prepared to participate in existing biochemistry research projects in the department.

Further particulars and application forms are available from the Registrar, University of Keele, Keele, Staff, ST5 5BG to whom completed applications should be returned before Friday 5 July 1985. (6827)A

CSIRO

AUSTRALIA

RESEARCH FELLOW

BIOTECHNOLOGIST

$A26,001 - $A38,243

DIVISION OF TEXTILE INDUSTRY GEELONG VIC

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Textile Industry is a member of the Institute of Industrial Technology.

FIELD: Microbiology, biotechnology, surface chemistry.

GENERAL: The Division of Textile Industry conducts research aimed at improving the utilization of Australian wool in the world textile industry. It undertakes physical and chemical investigations related to the conversion of raw wool for mill processing, improving manufacturing techniques and equipment, reducing the environmental impact of textile-processing, and improving end product performance.

DUTIES: The appointee will conduct research to establish the potential of biotechnology systems in wool-scouring effluent treatment processes and for modfying fibre characteristics. The appointee will be part of a multidisciplinary team which has extensive knowledge of wool processing and access to processing facilities.

QUALIFICATIONS: A PhD degree or equivalent qualifications in a relevant field of science plus demonstrable research ability. Applicants should possess a sound knowledge of microbiology and/or biotechnology and surface chemistry, in particular techniques related to the identification and optimisation of active species in broad enzyme systems.

TENURE: A term of 3 years with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No C8603, should be directed to:

The Chief
CSIRO Division of Textile Industry
PO Box 21
BELMONT VIC 3216
AUSTRALIA

by 4 weeks from date of publication

CISIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W1946)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT

Applications are invited for this post to work with Dr J Kay (in collaboration with Dr B M Dunn, University of Florida Medical School) on structure/activity relationships in aspartic proteinases and the selectivity of synthetic and naturally-occurring inhibitors. Duties to commence as soon as possible.

The appointment is for one year in the first instance, with a possible renewal for a second year. Salary range Grade 1B £6,600 - £7,055 per annum (under review). Research expertise with fractionation techniques including HPLC and experience of kinetic procedures would be an added advantage.

Applications (2 copies), together with the names and addresses of two referees should be forwarded to the Establishment Officer, University College, PO Box 78, Cardiff CF1 1XL. Closing date 4th July, 1985. Ref: 2956. (6775)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF GENETICS

POSTDOCTORAL RESEARCH FELLOW

Applications are invited from persons with relevant research experience in genetics physiology or metabolism biochemistry to develop a programme on the quantitative and physiology of growth and metabolism using selected lines of mice The project is supported by the AFRC in collaboration with the AFRC's Animal Breeding Research Organisation and Poultry Research Centre and is supervised by professor W G Hill.

The salary will be on the Research Associate 1A scale, minimum £7,520 pa. The appointment will be for three years in the first instance.

Further information can be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH8 9YL to whom applications, together with CV and names and addresses of three referees should be sent, quoting ref 5257. (6818)A

Applications are invited for a position in neurophysiology at the Assistant Professor level in the Department of Physiology at the University of Manitoba Faculty of Medicine. Candidates should have a PhD or equivalent, with two or more years of post-doctoral training. Preference will be given to individuals with experience and a continuing interest in electrophysiological analysis of neural networks and/or neurotransmitter actions using *in vitro* or *in vivo* systems. Send curriculum vitae, an outline of future research plans, and arrange for three letters of reference to be forwarded to: **Dr. Henry G. Friesen, Professor and Head, Department of Physiology, The University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, R3E 0WE Canada.** Deadline for receipt of applications is 1 September 1985. In accordance with Canadian immigration requirements this advertisement is directed to Canadian citizens and permanent residents. (NW1857)A

TRUDEAU INSTITUTE

VISITING INVESTIGATORS

The Trudeau Institute has openings for Visiting Investigators interested in spending up to two years working in the field of cancer immunology. The salary will range from $20,000 to $25,000, depending on experience University researchers interested in spending a sabbatical, or medical doctors wishing to obtain experience in a research laboratory are encouraged to apply

The Trudeau Institute is a not-for-profit pure research institute situated on the shore of Saranac Lake, 8 miles from Lake Placid, in the Adirondack Mountains of New York.

Send curriculum vitae and names of 3 references to: Dr. Robert J. North, Director, Trudeau Institute, Inc, PO Box 59, Saranac Lake, NY 12983. (NW1823)A

An Equal Opportunity Employer

Re-Advertisement

HOUGHTON POULTRY RESEARCH STATION

Grant-Aided by the Agricultural & Food Research Council

IMMUNOLOGIST

Applications are invited from immunologists to join a group studying cellular interactions in the immune system of chickens with the long term objective of providing a rational basis for the development and presentation of vaccines, particularly novel vaccines produced by genetic engineering techniques. The initial objective is the production and application of monoclonal antibodies specific for lymphocyte populations and subpopulations and the development of in vitro assays for soluble mediators such as interleukins.

Applicants should have a first or upper second class honours degree in a biological subject and preferably a PhD, with at least two years relevant post-graduate experience.

The appointments will be made in the Higher Scientific Officer grade, salary: £7,435 × 6 to £10.039.

The position is available for a period of three years, commencing on a date to be arranged prior to October 2nd, 1985.

For further details and application forms please contact the Secretary, John Andrews at Houghton Poultry Research Station, Houghton, Huntingdon, Cambs, PE17 2DA, tel St Ives (0480) 64101. Closing date for applications is 12th July 1985.

The Houghton Poultry Research Station is an Equal Opportunities Employer. (6802)A

UNIVERSITY OF NEWCASTLE UPON TYNE

READERSHIP IN CANCER PATHOLOGY

Applications are invited for an established Readership in Cancer Pathology in the Department of Pathology, jointly funded by the North of England Cancer Research Campaign and the University. Candidates should have substantial experience and interests in research in Cancer Pathology and must also have a good working knowledge of experimental techniques in molecular biology as applied to cancer research. The possession of a medical qualification and of the membership of the Royal College of Pathologists would be preferred, but other candidates with appropriate qualifications and experience will be considered. The successful candidate will be expected to take part in general departmental and teaching duties, under the direction of the Head of the Department.

Salary will be at a point on either the clinical Reader's scale or the non-clinical Reader's scale, with membership of the appropriate superannuation scheme. An appropriately qualified clinical appointee contributing at least two sessions to the clinical service would be offered honorary consultant status by the Newcastle Health Authority.

Applications (15 copies), giving the names of three referees must be lodged with the Senior Assistant Registrar, The Medical School, University of Newcastle upon Tyne, Framlington Place, Newcastle upon Tyne NE2 4HH, not later than 12 July 1985, from whom further particulars can be obtained. (Applicants from outside the British Isles may submit one copy only). (6779)A

THE UNIVERSITY OF NEW SOUTH WALES

Sydney, Australia

LECTURER IN SCHOOL OF ANATOMY

Applicants should have a degree in medicine or relevant science and appropriate postgraduate qualifications Clinical experience desirable. Duties will include teaching gross anatomy and at least one other subject, and undertaking research relevant to the School's interests

In addition to salary, a paraclinical loading of $A6,558 per annum will be paid to a medically qualified appointee.

Appointment will be on the basis of a contract with provision for conversion to tenure

Further information from Professor F W D Rost, Head of School (02) 697-2481 or c/o University of New South Wales, PO Box 1 Kensington, NSW 2033, Australia.

Applications close 8 July 1985

Salary: $A26,236 range $A34,467. Commencing salary according to qualifications and experience.

For further information about conditions of appointment and method of application write to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Equality of employment opportunity is University policy. (W1942)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF IMMUNOLOGY

SENIOR TECHNICIAN

required for large scale production of monoclonal antibodies for in vivo therapy by large scale screening, and investigation of reagent combinations on selected leukaemias and lymphomas.

Salary range £7,521 — £9,935 (under review) plus £1,042 London Allowance. 5-year appointment.

Further particulars and application form available from the School Office, RFHSM, Rowland Hill Street, London, NW3 2PF (010-794 0500 Extn 4262). Closing date 5th July 1985. Please quote reference J/ST. (6824)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF PHYSIOLOGY

RESEARCH ASSISTANT & RESEARCH TECHNICIAN (2 POSTS)

Applications are invited for a Research Assistant, Grade RA 1A, and a Grade 3 Research Technician to work on a project investigating neuronal 5-hydroxytryptamine receptors using in vitro electrophysiological methods. The posts are funded by the Wellcome Trust and both are for 3 years. Commencement of duties to be arranged.

Applicants for the Research Assistant post should have a good Honours degree in a relevant biological science, but Post-doctoral applicants will be considered. Experience of electrophysiological techniques will be an advantage. Salary Grade 1A £7,520 per annum.

Applicants for the Grade 3 Technician post should have as minimum qualifications ONC, TEC or equivalent or a degree in biological science. Starting salary will be in the range £5,399 - £5,701 per annum. Some experience in the field of electrophysiology and/or pharmacology will be an advantage.

For further details, write or telephone Professor D I Wallis, (0222) 44211 Ext 2259.

Applications (2 copies) giving details of age, qualifications and experience, together with the names and addresses of two referees, should be forwarded to the Establishment Officer, University College, PO Box 78, Cardiff, CF1 1XL. Closing date 4th July, 1985. Ref: 2954. (6774)A

UNIVERSITY OF OXFORD

DEPARTMENT OF AGRICULTURAL SCIENCE

SOIL CHEMIST

A post-doctoral research assistant with experience of soil chemistry and the simulation of complex dynamic systems is required as soon as possible to carry out research under the supervision of Mr P H Nye on the development and testing of a model of nitrogen losses from soil by ammonia volatilization. The post is for two years on salary scale 1A, and candidates should preferably be aged 28 or under. Applications, including a curriculum vitae and the names of two referees, should be sent by 28 June to the Administrator, Department of Agricultural Science, Parks Road, Oxford, OX1 3PF. (6764)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

LECTURESHIP IN BIOCHEMISTRY

Applications from candidates with appropriate qualifications and research interest in Molecular Cell Biology are invited for a Lectureship which is available from 1 October 1985 in the above Department, in which Professor G B Warren has recently been appointed to the Chair of Biochemistry.

Salary scale currently £7,520 - £14,925 but due for review. Initial placing dependent on qualifications and experience of the appointee. Grant towards removal expenses to Dundee.

Applications, containing full career details and the names of three referees should be lodged as soon as possible with the Personnel Officer, The University, Dundee, DD1 4HN. Please quote reference EST/18/85J. (6768)A

THE UNIVERSITY OF SYDNEY

CHALLIS CHAIR OF ANATOMY

Reference No 19/02

Applications are invited from suitably qualified candidates for the Challis Chair of Anatomy. The Chair has become vacant following the retirement of Professor M J Blunt.

Applicants should have a wide experience in the teaching of Anatomy and should be familiar with the requirements of teaching Anatomy to medical and dental students. Candidates will be expected to have an established reputation in research and to be actively engaged in research in anatomy or related field

Possession of a medical degree is preferred. Non-medical graduates are also invited to apply.

Salary will be at the rate of $AS54,948 per annum plus a pre-clinical loading of $A4,919 per annum where appropriate.

Applications in duplicate, quoting reference no, including curriculum vitae, list of publications and the names and addresses of three referees, by 12 July 1985, to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information is available.

The University reserves the right not to proceed with any appointment for financial or other reasons.

Further information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

(W1936)A

THE SCHOOL OF PHARMACY

University of London

CANCER RESEARCH CAMPAIGN PROTEIN SEQUENCING FACILITY

RESEARCH ASSISTANT

Applications are invited from persons suitably qualified in protein chemistry and/or biochemistry to manage the Applied Biosystems gas phase automatic protein sequencer facility funded by the CRC This new centre for microsequencing proteins and peptides related to the study of cancer has the latest design of on-line automatic HPLC equipment and computerised data storage. It is located in the Department of Pharmaceutical Chemistry, which has excellent facilities to pursue multi-disciplinary research in modern chemistry, biochemistry and molecular biology.

Applicants should be graduates (or equivalent), preferably with PhD, and have experience in protein chemistry and in running similar equipment. The successful candidate will be encouraged to pursue a research programme towards a higher degree or at postdoctoral level.

Appointment will be in the Research Staff 1A range (£7520 — £12150, plus London Allowance of £1233), at a point commensurate with qualifications and experience

Further details may be obtained from Dr Alastair Aitken, on 01-837 7651, be sent to: Personnel Officer, School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, to arrive by 5 July 1985.

(6786)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF IMMUNOLOGY

SENIOR RESEARCH FELLOW

(Senior Lecturer grade) IN CLINICAL IMMUNOLOGY

required for co-ordination of immunotherapy with monoclonal antibodies and cyclosporin-A in patients undergoing kidney, bone marrow (BMT), heart and liver transplantation This is an opportunity for a physician to specialize in Clinical Immunology including aspects of immunotherapy.

Salary range £16,240 — £22,620 (under review) plus £839 London Allowance 5-year appointment.

Further particulars available from the School Office, RFHSM, Rowland Hill Street, London, NW3 2PF (01-794 0500 Extn 4262) to which applications (full curriculum vitae and names and addresses of two referees) should be sent by 5th July 1985 Please quote reference IMM/SRF.

(6822)A

TECHNICIAN or EMBRYOLOGIST with experience in mammalian embryology, required to work for IVF clinic in Athens. Salary negotiable. Interested persons should write in confidence to Dr H G Massauras, 3 Marasli Street, Athens 106-76, Greece. (W1920)A

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF PHYSICS

Applications are invited for the post of

EXPERIMENTAL OFFICER

to work with a research group on the physics of semiconducting Low Dimensional Structures (LDS) using samples prepared by Molecular Beam Epitaxy (MBE).

The person appointed, who will be qualified to graduate level, will be expected to assist with the growth, processing and subsequent characterisation of layers grown on a Varian GEN II MBE machine.

Familiarity with some or all of the following techniques would be an advantage: ultra high vacuum systems, Auger and RHEED spectroscopy, mask aligning and bonding and working under "clean room" conditions.

This is a permanent University appointment in an area of Physics which is currently receiving major funding from the Science and Engineering Research Council and the University.

Salary will be within the range of £6,600 — £10,330 per annum (under review).

Further particulars and forms of application, returnable not later than 30 June 1985, may be obtained from the Staff Appointments Officer, Univeristy of Nottingham, University Park, Nottingham, NG7 2RD. Ref No. 1000. (6791)A

U M I S T

POST-DOCTORAL RESEARCH ASSISTANT

Protein Engineering

A Post-doctoral Research Assistant is required to work on an SERC-funded project which will analyse and alter the active site of eukaryotic Superoxide Dismutase both to elucidate the enzyme's catalytic mechanism and to confer novel activities upon it. The project will exploit site-directed mutagenesis to introduce defined changes in the enzyme's active site and will analyse their effect on protein structure and function using X-ray absorption spectroscopy (XAS) The mutagenesis and related biological experiements will be performed in the laboratory of Dr S G Oliver in the Department of Biochemistry and Applied Molecular Biology. This superbly equipped, modern Department has a dedicated facility for both oligonucleotide and peptide synthesis. The XAS and structural analyses will be carried out in the laboratory of Dr N J Blackburn (Dept. of Chemistry) and at the SERC Synchrotron Radiation Facility in nearby Daresbury

The post, which is funded for three years, would suit a PhD molecular biologist with experience in recombinant DNA technology. An interest in, and knowledge of, biophysics or physical chemistry would be advantageous but not essential. Commencing salary will be within the scale £7520 - £12150 per annum (under review).

For further details contact Dr S G Oliver (061-236 3311 extn. 2172) or Dr N J Blackburn (extn. 2109). Applications, quoting reference BIO/87, including a curriculum vitae and the names of two referees should be sent to Dr S G Oliver, Department of Biochemistry and Applied Molecular Biology, UMIST, P O Box 88, Manchester M60 1QD.

RESEARCH ASSISTANTS

Molecular Biology Of Lignin Biodegradation

Vacancies exist in the Department of Biochemistry and Applied Molecular Biology for two Research Assistants in a Group which is funded jointly by the AFRC and BP's Venture Research Unit The interests of the Group are in lignin solubilisation by white rot fungi and actinomycete bacteria. A wide range of molecular genetical, microbiological and analytical methods are currently being used in work to identify and characterise genes coding for the enzymes involved, and their controlling elements. These include HPLC analysis, protein purification, cDNA and genomic cloning, use of synthetic oligonucleotide probes, DNA sequence analysis and site-directed mutagenesis There is also extensive collaboration with other groups in this excellently equipped and interactive department

Applicants must have relevant experience at the graduate or post-doctoral level and must be available for interview.

The appointments will be for 18 months in the first instance, with the prospect of renewal and the commencing salaries will be within the range £6600 - £12150 per annum (under review)

Applications, quoting reference BIO/88, including a curriculum vitae and the names of two referees should be sent to Professor P M A Broda, Department of Biochemistry and Applied Molecular Biology, UMIST, P O Box 88, Manchester H60 1QD, from whom further information can be obtained (Tel): 061-236 3311 ext. 2119).

The closing date for ALL the above posts is 28 June, 1985.

(6795)A

ENDOCRINOLOGY BIOCHEMISTRY/ PHYSIOLOGY

Postdoctoral Opportunities

Broad range of Endocrine research projects: (i) isolation and identification of pituitary and lung peptides; (ii) physiologic and pharmacologic action; (iii) growth and control of function of fetal adrenals; (iv) role of growth factors in fetal development

Send curriculum vitae, bibliography, three letters of recommendation, and short statement regarding career goals, interests and experience to: Dr Samuel Solomon, Endocrine Laboratory, Royal Victoria Hospital, 687 Pine Ave. West, Montreal, Quebec H3A 1A1. (NW1772)A

POSTDOCTORAL/ ASSISTANT PROFESSOR

position available immediately in the Surgical Immunology Laboratory, V A. Medical Center, Miami, Florida, affiliated with the Departments of Surgery and Urology at the University of Miami, School of Medicine. The research revolves around new applications of multiparameter flow cytometry in the characterization of solid tumor cell kinetics, antigens and metalolic states. The candidate should be familiar with the principles of flow cytometry and monoclonal antibody staining/production techniques. Some computer programming experience is desirable. Send curriculum vitae to: **Norman L. Block, M.D., Department of Urology, University of Miami, School of Medicine, P.O. Box 06217, Miami, Fla. 33101; telephone: 305-547-6630.** *An Equal Opportunity/Affirmative Action Employer.* (NW1860)A

THE QUEEN'S UNIVERSITY OF BELFAST

RESEARCH ASSISTANT

Department of Applied Mathematics and Theoretical Physics

This post, funded by SERC, involves work on maintaining an Atomic Data Bank for basic atomic data which will be used in a number of branches of theoretical physics including atomic physics, fusion physics and astrophysics. Extensive use of computers will be involved; the Data Bank is set up on a local VAX 11/750, and its main use is to capture data from a CRAY-1S at the University of London Computer Centre, via data links.

Applicants must have a good honours degree *and* postgraduate research experience in a relevant field. A knowledge of atomic physics, astrophysics, or information retrieval would be an advantage.

Salary up to £9390 per annum. The post is tenable for one year, starting as soon as possible.

Curriculum vitae, giving the names and addresses of two referees, should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland Closing date: 1 July 1985 (Please quote Ref. 85/D). (6810)A

IMMUNOLOGY PhD

wanted to run transplant immunology laboratory. Must have experience in cellular immunology — in vitro immune responses, cell separation and culture techniques, safe use of radioactive isotopes — and be willing to direct and assist research technicians in performance of simple and complex procedures. Some experience with UV irradiation and epidermal cell reactions preferred; 2 to 3 years of postdoctoral experience required. Applicants should submit curriculum vitae to: **Jay C. Fish, MD, Department of Surgery, University of Texas Medical Branch (UTMB), Galveston, Texas 77550.**

UTMB is an Affirmative Action/Equal Opportunity Employer. (NW1839)A

MOLECULAR BIOLOGIST

To engage in research regarding causes of and cures for autoimmune diseases; studies growth, structure, development and general characteristics of micro-organisms believed to cause arthritis and other autoimmune diseases.

Specifically, successful applicant will study interactions between La protein, virus RNA molecules, and patient anti-La antibodies. Req.'s PhD in Molecular Biology, Virology, Biochemistry or Medical Biophysics; 2 yrs. exp in job being offered or as a Postdoctoral Fellow/Molecular Biologist; and thorough knowledge of an substantial exp. in adenovirus VA RNAs and La protein antigens. La Jolla, California, job site. $35,000 per year. If offered employment, must show you have the legal right to work.

Send this ad and your résumé to job no 1760 PO Box 865, Sacramento, California 95804, not later than June 28 1985. (NW1840)A

UNIVERSITY OF WISCONSIN-MADISON

MYCOLOGY/MICROBIAL ECOLOGY

RESEARCH ASSOCIATE (postdoctoral) position available 1 June 1985 on the BIOTECHNOLOGY and microbial ecology of fungal pathogens (biocontrols) to watermilfoil Research aspects include mass culture and strain improvement techniques, interaction with other control measures, and tracking marked populations in water and sediment Funding for two years. Salary competitive and commensurate with qualifications. **Send résumé with names of 3 references to: Dr. John H. Andrews, Department of Plant Pathology, 1630 Linden Drive, Madison, WI 53706.** *jAn affirmative action/equal opportunity employer.* (NW1835)A

HLA LABORATORY DIRECTOR:

Ph.D. immunologist with previous experience and research interest in human histocompatibility testing needed to develop the histocompatibility laboratory at The University of Texas Health Science Center at San Antonio. Please send inquiries or curriculum vitae, current laboratory procedure manual, and UCLA and/or SEOPF quality control data for the past year to: **Callann T. Lum, M.D., Director, Organ Transplantation Programs, Department of Surgery, The University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Drive, San Antonio, Texas 78284.** (NW1861)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL

Food Research Institute

PROTEIN BIOCHEMIST

A vacancy has arisen for a protein biochemist to investigate what structural features in the collagen molecule determine the mechanical strength of gelatin gels. The appointed scientist will work closely with both the Collagen Section and Myofibrillar Structure Section. The project will require the characterisation of a variety of gelatin preparations, collagen chains and peptide fragments, together with mechanical studies on gelatin gels and electron microscopy. The post is financed by industry and is for three years.

Qualifications: First of upper second class honours degree in biochemistry or related subject with at least 2 years relevant post-graduate research experience for appointment at HSO, 4 years for SSO. A PhD and experience of electorn microscopy or mechanical measurements would be an advantage or equivalent experience.

Salary: £7,435 — £12,020 according to qualifications and experience.

Please apply to: Personnel Officer AFRC Food Research Institute Langford Bristol BS18 7DY (Ref 85/11)

The AFRC and the Grant-Aided Institutes of the AFRS are Equal Opportunities Employers. (6788)A

CAMBRIDGESHIRE COLLEGE OF ARTS AND TECHNOLOGY

DEPARTMENT OF SCIENCE

LECTURER I in Geology

Required from 1st September 1985 to teach either sedimentary and organic geochemistry or geotechnical engineering to final honours degree level. A strong interest in research and field work is necessary. Other teaching will include supervision of student projects. Development of links with industry is encouraged.

Salary scale LI £5910 — £10512 (award pending), starting point according to qualifications and experience.

Details and form, to be returned by 28th June, from Administrative Assistant, Department of Science, CCAT, East Road, Cambridge CB1 1PT, Tel (0223) 352992. (6782)A

UNIVERSITY OF EDINBURGH

DEPARTMENTAL SUPERINTENDENT

Applications are invited for the above post in the Department of Zoology, West Mains Road. The successful applicant will be responsible for the day-to-day running of the Department including general supervision, selection and training of technical staff, purchasing and maintenance of equipment, safety and security. Applicants should have several years of supervisory or middle management experience preferably in University laboratories. Salary on scale £10,504 — £11,396 (under review). Ref NT546

Further particulars, where available, and application forms may be obtained from the Personnel Office, University of Edinburgh. 63 South Bridge, Edinburgh, EH1 1LS. Tel 031-556 2930. (24 hour answering service) (6815)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF ANIMAL PHYSIOLOGY AND NUTRITION

LECTURER

Applications are invited for the above post available from 1 August 1985. Candidates should have a PhD in animal science, preferably involving some study of pigs, and should have some postdoctoral research experience.

Salary on a scale for Lecturers (£7,520 - £14,925) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference no 61/19.

Closing date for applications 4 July 1985. (6797)A

UNIVERSITY OF LONDON

Institute of Neurology

Applications are invited for a

RESEARCH ASSISTANT

post available until September 1986 to work on a project to determine the in vitro chemosensitivity measurement of human glioma within the Neuro-oncology section of the Department of Neurological Surgery. Aplicants should have experience in tissue culture work. Salary within the range £7,980-£8,920 plus £1,233 London Allowance.

Further particulars may be obtained from Mr D G T Thomas, FRCSE, Department of Neurological Surgery, Institute of Neurology, The National Hospital, Queen Square, London WC1N 3BG, to whom applications should be forwarded within two weeks of the appearance of this advertisement. (6803)A

ROYAL HOLLOWAY AND BEDFORD COLLEGES

Egham Hill, Egham, Surrey TW20 0EX

SCIENTIFIC OFFICER

Monoclonal Antibody Production

Well qualified graduates in a Biological Science required for three years for the posts (UGC funded) of Scientific Officer to develop a central service unit for the production of monoclonal antibodies. At least three years experience in mammalian cell culture and preferable hydridoma production and screening, is essential.

Salary scale £7,833 — £10,153 inclusive of London allowance

Please send self addressed envelope for further details to Mrs D J Odds, Personnel Officer. (6785)A

BLAND-SUTTON INSTITUTE OF PATHOLOGY

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL, London W1P 7PN

RESEARCH ASSISTANT

required to raise monoclonal antibodies with a group investigating the expression of antigens in breast cancer. For 1 to 2 years, (starting salary up to £7,833 per annum), to start as soon as possible Experience in monoclonal antibody production/ tissue culture would be advantageous.

Applications in the form of cv plus names and addresses of 2 referees to Dr A Leathem at the above address. (6828)A

ASSISTANTSHIPS

UNIVERSITY OF CAMBRIDGE
UNIVERSITY CHEMICAL LABORATORY

POSTDOCTORAL ASSISTANTSHIP

Applications are invited from molecular biologists for work on the cloning and expression of the genes for the key enzymes on the biosynthetic pathways to haem, vitamin B_{12} and related macrocycles. This will be in collaboration with Dr C Abell and Professor A R Battersby.

The appointment from a mutually agreed date in 1985 is for up to 2 years at a starting salary within the Scale £7520 (for 24 years of age) to £8920 (for 27 years of age) with an increment after one year. Applications with curriculum vitae and 2 referees' names should be sent as soon as possible to: Professor A R Battersby, University Chemical Laboratory, Lensfield Road, Cambridge, CB2 1EW (6812)P

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MICROBIOLOGY

MICROBIAL ECOLOGY

Applications are invited for an NERC POSTDOCTORAL RESEARCH ASSISTANTSHIP

tenable for three years from 1 October 1985. The project is to study the recycling of chitin in estuaries with Professor G W Gooday and Dr J I Prosser.

Salary within range £7,520 - £12,150 on the 1A scale for research and analogous staff (under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 1st July 1986. (6767)P

DURHAM UNIVERSITY
DEPARTMENT OF CHEMISTRY

Applications are invited for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

tenable for up to 3 years, to work with Dr D Parker on the synthesis of new anti-cancer drugs. Applicants should either have a strong background in synthetic organic chemistry (particularly bio-organic chemistry) The project is in collaboration with Celltech Ltd, and the starting salary will be £7520 or £7980 per annum on Range 1A plus superannuation (under review).

Applications (3 copies) naming 3 referees should be sent by 1 July 1985 to the Registrar, Science Laboratories, South Road, Durham, DH1 3LE (6790)P

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF AGRICULTURAL BIOLOGY

MAFF RESEARCH STUDENTSHIP

"Investigation of earliness and frost resistance in winter rye"

The aims of the project are to investigate the physiological basis of the earliness and frost resistance of winter rye, to assess intercultivar variation in these properties and to evaluate both tetraploid and diploid winter rye cultivars in comparison with perennial ryegrass and triticale as sources of early forage in both lowland and upland pastures.

While all the aims will be included in the programme of research, the emphasis of physiological, agronomic or genetic aspects will depend on the interests of the graduate appointed.

Applicants should have, or expect to obtain this summer, a first or upper second class honours degree, or equivalent, in Agricultural Botany, Botany or a related subject.

Applications in the form of a curriculum vitae should include the names and addresses of two academic referees and should be sent to Dr W S Stewart, Department of Agricultural Biology, The University, Newcastle upon Tyne, NE1 7RU, from whom further details can be obtained. Closing date 5 July 1985 (6821)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

SERC RESEARCH STUDENTSHIP

Applications are invited for an SERC Research Studentship, commencing October 1985, leading to the degree of PhD The successful candidate will join an active research group investigating the molecular basis of glucose transport and its regulation in the membranes of mammalian cells.

Applicants should have, or expect to obtain, a first or upper second class honours degree in Biochemistry or a related discipline, and should have strong interest in cell and/or molecular biology. Applications, containing a CV and the names, addresses and telephone numbers of two professional referees, should be sent as soon as possible to Dr S A Baldwin, Department of Biochemistry and Chemistry, Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF, from whom further details may be obtained. (6776)F

STUDENTSHIPS

UNIVERSITY OF LEICESTER/CRANFIELD INSTITUTE OF TECHNOLOGY

POSTGRADUATE STUDENTSHIP IN MOLECULAR GENETICS

Applications are invited for a postgraduate studentship in the Department of Genetics, University of Leicester, for three years commencing October 1st 1985, leading to the degree of PhD The project will involve the application of recombinant DNA techniques to the study of secretion of a bacterial toxin by E coli. The project involves collaboration between the Institute of Biotechnology at Cranfield, the Department of Genetics, Leicester and ICI, Agricultural Division, Billingham. The work will be carried out at Leicester as part of a small team investigating the molecular biology of haemolysin secretion. Applicants who hold or expect to obtain at least a 2i degree in a relevant Biological Science should apply to: Professor I B Holland, Department of Genetics, University of Leicester, University Road, Leicester LE1 7RH enclosing a brief curriculum vitae and the names and addresses of two Referees Closing date for applications July 1st 1985. (6817)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF NEUROLOGICAL SCIENCE

SERC-CASE PhD STUDENTSHIP
(Jointly with Eli Lilly Research Ltd)

Immunology/cell biology graduate required to study the functions of germinal centre cells in mice and man, in an MRC-funded group of clinical and basic scientists working on the immunology of myasthenia gravis. The 'industrial' component will be at Lilly Research, Windlesham, and will probably require about six months.

For further information please contact Dr N Willcox, Department of Neurological Science, Royal Free Hospital School of Medicine, Rowland Hill Street, London, NW3 2PF (01-794 0500 Extn 4386) to whom applications giving the names of three referees should be sent by 28 June 1985. (6799)F

UNIVERSITY OF EDINBURGH MEDICAL SCHOOL
DEPARTMENT OF SURGERY

RESEARCH STUDENTSHIP IN ENDOCRINOLOGY AND METABOLISM

Applicants are invited for a postgraduate studentship tenable for 3 years starting in October 1985 and leading to a PhD Degree The research topic includes an investigation on the mechanism of action of prolactin and other growth hormones in the human prostate.

Applicants should have or expect to have at least, Upper Second Class Honours in Biochemistry, Pharmacology or other biological sciences. Applications, which should include a curriculum vitae and the names of two referees, should be sent to Dr F K Habib, Department of Surgery, University of Edinburgh Medical School, Teviot Place, Edinburgh EH8 9AG. (6816)F

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF PHYSICS

RESEARCH STUDENTSHIP IN SOLAR PHYSICS

A studentship is available for a suitably qualified and motivated student to undertake reearch with the solar physics groups to study solar oscillations leading to a PhD degree. The work involves the development of new resonant scattering spectrometres, the collection of data at remote sites (Australia, Hawaii and Tenerife) and the subsequent analysis and interpretation of the data.

For application form please contact Mrs Muriel Mason, Department of Physics, University of Birmingham, PO Box 363, Birmingham B15 2TT. (021 472 1301 ext 3265) (6825)F

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF BIOCHEMISTRY

RESEARCH STUDENTSHIPS

Applications are invited from suitably qualified graduates or those expected to graduate shortly for Research Studentships tenable in the Department of Biochemistry for the Session 1985-86. Studentships are the same value as those awarded by the various Research Councils or the DES plus tuition fees The following research fields may be available to suitable candidates: (1) Membrane bound enzymes. (2) Glycosaminoglycans of blood vessel surfaces. (3) Alginate modifying enzymes. (4) Hepatic anti-tumour agents.

Further particulars can be obtained from Professor K S Dodgson, Department of Biochemistry, University College, PO Box 78, Cardiff CF1 1XL. Ref: 2961. (6773)F

FROST EXHIBITION RESEARCH STUDENTSHIP in Freshwater Biology

The Freshwater Biological Association is offering one three-year postgraduate Studentship to start in summer 1985 at one of its Laboratories. Research projects in several fields of freshwater biology are available for interested students. Alternatively students may propose their own research project in any field of freshwater biology. A good honours degree in science or its equivalent is essential for registration at Lancaster, Reading or another appropriate university. The studentship will be awarded in open competition to the person showing most promise of making a successful career in creative research in freshwater biology. Basic maintenance grant of 10% above the normal Research Council grant and allowances pa plus fees etc.

Full details from The Assistant Director, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP (Tel 096-62 2468). Closing date 26th June 1985. Selected candidates will be interviewed on 12th July 1985. (6796)F

Continued on pages 18, 20

Special Training Fellowships in Recombinant DNA Technology

Applications are invited for fellowships for any period from 6 months to three years commencing on or after 1 May 1986 from scientists requiring training in recombinant DNA techniques. Applicants may be young postdoctoral scientists (or those just completing PhD's) or more mature scientists with established reputations in other areas wishing to enter this field. Permanent academic staff with unpaid leave of absence may apply. Applicants will be expected to propose their own training programme prepared in collaboration with the proposed supervisor.

These fellowships are tenable in any UK institution offering training appropriate to the applicant's needs. UK residents temporarily working abroad may apply.

MRC
Medical Research Council

Application forms, and further details may be obtained from Training Awards Group, Medical Research Council, 20 Park Crescent, London W1N 4AL. (Tel: 01-636 5422 Ext 448)

Closing date: 15 October 1985

(6766)E

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

POST DOCTORAL FELLOWSHIP

Applications are invited for a Research Fellowship funded by the Medical Research Council to study recognition signals in adenovirus replication. The applicant should prefereably have some experience in either cloning or hybridoma technology and will become part of the Molecular Virology Group in the Department. The project will be under the supervision of Professor W C Russell from whom further information may be obtained (Telephone 0334 76161 ext 295).

The appointment will be for 3 years, starting as soon as practicable. Starting salary at appropriate point within range £7,520 to £10,330 per annum on the 1A Research scale, plus superannuation

Applications (two copies preferably in typescript) with the names of two referees should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ to arrive not later than 2nd July 1985. (6813)E

Wellington Medical Research Foundation Inc.
MALAGHAN RESEARCH FELLOWSHIP

The Wellington Medical Research Foundation Inc. invites applications for the position of Malaghan Research Fellow to be held at the Wellington Cancer and Medical Research Institute, Wellington Clinical School of Medicine, Wellington, New Zealand. The applicant should be a research worker with evidence of capacity to undertake original research. The applicant must possess a higher qualification and the field of research will be in the general field of cancer with preference for haematological malignancies. The annual salary will depend on qualifications and experience but will be on the University Lectureship scale and within the range of NZ$23,622 - NZ$27,928. A particularly well qualified person could be appointed at a higher level on the salary scale. Adjustments will be made to cover increases in cost of living in line with the wage adjustment of University staff. The appointment is for four years. Assistance towards transport expenses is available. **Conditions of appointment, method of application and other information may be obtained from the Director of the Wellington Cancer and Medical Research Institute, Wellington Clinical School, Wellington Hospital, Wellington 2, New Zealand, or from the office of the High Commission, New Zealand House, London. Applications close with the Secretary of the Wellington Cancer and Medical Research Institute on 31st August, 1985.** (W1940)E

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP

Fourier-Transform Infra-red Spectroscopy

Applications are invited for a Post-doctoral Research Fellowship to develop applications of Fourier-Transform Infra-red Spectroscopy in conjunction with Dr G J Buist. The Department has recently purchased a Perkin-Elmer model 1750 FTIR spectrometer, and wishes to develop applications to polymer chemistry, food science, biochemistry and microbiology. Applicants should have had research experience in infra-red spectroscopy. The appointment is available from Sept/Oct 1985 for one year at a salary of £7,520 per annum. Superannuation is under USS conditions.

Applications in the form of a curriculum vitae (3 copies) including the names and addresses of two referees should be sent to the Personnel Office (JLG), University of Surrey, Guildford, Surrey, GU2 5XH by 12 July 1985 quoting reference 397/N. (6794)E

EMBO
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
Autumn 1985 — Awards
Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R. Germany.

(W1893)E

COLUMBIA UNIVERSITY
Department of Biochemistry and Molecular Biophysics

A postdoctoral research fellowship is available immediately for studies on the structure of a Na/K-ATPase The applicant should have a background in either synthetic organic chemistry or the biochemistry of integral membrane proteins. The work will involve both the preparation of heavy atom labeled ligands, and the reassembly and reconstitution of the ATPase subunits Applications, including a curriculum vitae and the names of two referees should be sent to.

Dr. I.S. Edelman
Department of Biochemistry & Molecular Biophysics
Columbia University
630 West 168 Street

Brunner Strasse 59
A-1235 Wien, Austria (W1951)E

THE OPEN UNIVERSITY
Faculty of Science
BIOLOGY DEPARTMENT
POSTDOCTORAL FELLOWSHIP IN MOLECULAR GENETICS

Applications are invited for an immediately available MRC funded postdoctoral fellowship to work on the molecular genetics of human lactase using recombinant DNA techniques. This is a collaborative project between the Open University and the MRC Human Biochemical Genetics Unit, University College, London. The aim is to understand the control of lactase expression and the evolution of lactase persistence. The appointment will be for 3 years on the 1A Scale for Research and Analogous Staff (£7520 — £12150 pa under review). Maximum initial salary will be £8920.

Application forms and further particulars are available from Dr J W R Smith (4817/1), Administrative Assistant (Science), Faculty of Science, The Open University, Walton Hall, Milton Keynes, MK7 6AA or telephone Milton Keynes (0908) 653993: there is a 24 hour answering service on Milton Keynes 653868.

Closing date for appllications: 5th July 1985. (6808)E

POST-DOCTORAL FELLOWSHIP POSITION

Applications are invited from chemists, pharmacologists and biochemists to work on the application of mass spectrometry to nutrition based research. Applicants should have experience in modern methods of analysis together with an interest in mass spectrometry. The position will involve collaboration with a multi-disciplinary group of scientists working in the Clinical Nutrition Research Unit. It is envisaged that two major areas of research will be involved. First, determination of glucose production rates in children with glycogen storage disease and second the analysis of urinary prostaglandin metabolites. Salary for this position will be commensurate with training and experience.

The mass spectrometry laboratory is equipped with 3 magnetic sector instruments and 5 quadrupoles. Capabilities of the laboratory include FAB/MS, Thermospray LC/MS, Accurate mass determinations and capillary column GC NICI/MS. **Applications including full personal details togehter with the names and addresses of at least two referees should be sent to Ian A. Blair, Ph.D., Department of Pharmacology, Vanderbilt University, Nashville, TN 37232 not later than June 21, 1985.** (NW1855)E

ANNOUNCEMENTS

American Teknos, Inc.

American Teknos, an international technology development and transfer company is seeking health-care technologies in the early development or invention stage.

If you are an individual company or research institution with technology in a transferable state, i.e. patentable, we can provide funds or find suitable industrial partner to develop your invention. We specialize in bringing advanced technology to market

American Teknos can provide.
—funding for development or start-up capital
—personnel and facilities
—market research & assessment
—business plans
—consultation in appraising the commercial potential of technology
—representation or distribution in the United States

If you think we can serve your needs, or you have a qualified technology, patent or product, please send non-confidential details to:

Mr. Joseph Fanelli, Chairman
American Teknos, Inc.
14710 Greenleaf St, Sherman Oaks, CA 91403

SEMINARS and SYMPOSIA

NOVO RESEARCH SEMINAR

"The Biogenesis of Regulatory Peptides"

22nd-23rd AUGUST 1985
Novo Industri A/S, Bagsvaerd, Copenhagen, Denmark

Organising committee: J.F. Rehfeld, T.W. Schwartz, L. Olsson, U.V. Lassen.

There will be five sessions:

I. Post-Transcriptional Processing:
chairman Niels Ful, Novo's Genetic Laboratory
Lecturers:
S. Nakanishi, Kyoto University
J.F. Habener, Massachusetts General Hospital, Boston
D. Richter, Hamburg University

II. Intra-Cellular Targeting of Precursors:
chairman Ove Noren, University of Copenhagen
Lecturers:
D.I. Meyer, EMBL, Heidelberg
R.B. Kelly, University of California, S.F.

III. Proteolytic Processing:
chairman Howard S. Tager, The University of Chicago
Lecturers:
J. Thorner, University of California, Berkeley
T.W. Schwartz, MRC, University Hospital, Copenhagen
K. Docherty, University of Birmingham
G. Kreil, Austrian Academy of Science, Salzburg

IV. Amino Acid Derivatization:
chairman G. Kreil, ibid.
Lecturers:
D.G. Smyth, MRC, London
B.A. Eipper, The Johns Hopkins University, Baltimore
C.C. Glembotski, University of Pennsylvania
G.S. Baldwin, Royal Melbourne Hospital
W.B. Huttner, Max-Planck Institute, Munchen

V. Specific Peptide Systems:
chairman Jens Vuust, Arhus University
Lecturers:
H.S. Tager, the University of Chicago
T. Yamada, the University of Michigan
J.F. Rehfeld, University Hospital, Copenhagen

Participation in the seminar itself is free.
Travel and accommodation expenses will have to be met by participants.
Closing date for registration is 1st August 1985.
For details and registration, please contact:
Mrs. Karen Rimmer, Novo Industri A/S,
Novo Alle, DK-2880 Bagsvaerd, Denmark
Tel: (02) 982333, extension 3531.

STUDENTSHIPS

THE SCHOOL OF PHARMACY
University of London
DEPARTMENT OF PHARMACOLOGY

MRC RESEARCH STUDENTSHIP

Applications are invited from graduates holding, or expecting to obtain, an upper second or first-class degree in Pharmacology or a related subject, for a three year MRC studentship. The successful candidate will study the pharmacology of excitatory and inhibitory synaptic transmission in identified spinal neurones evoked by stimulation of specific brain stem areas. This project will utilise, in particular, the microiontophoritic technique.

Letters of application, together with a full CV and the names, addresses and telephone numbers of 2 referees, should be sent to: Dr J Davies, Department of Pharmacology, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, to arrive by 1 July 1985. (6804)F

Continued on page 20

UNIVERSITY OF WALES COLLEGE OF MEDICINE
DEPARTMENT OF CHILD HEALTH

(re-advertisement)

Applications are invited for a postgraduate scholarship to investigate androgen action and metabolism in disorders of sexual differentiation in humans, using tissue culture and cell fractionation techniques.

Applicants should have, or expect to gain, a first or upper second class honours degree in Biochemistry or a related science discipline.

The scholarship will commence in September 1985 and is tenable for a 3 year period (subject to a probationary year). The results are expected to be submitted for a PhD degree.

Further particulars and application forms (quoting ref No C10/61) may be obtained from the Registrar and Secretary, University of Wales College of Meducine, Heath Park, Cardiff, CF4 4XN (Tel No 0222/755944 Ext 2296) as soon as possible. Closing date for application: 12th July, 1985.

(6830)H

CONFERENCES and COURSES

INSTITUTES OF PSYCHIATRY, NEUROLOGY AND OPTHALMOLOGY
(British Postgraduate Medical Federation, University of London)

MSc in NEUROCHEMISTRY

This is a one-year Course leading to the degree of MSc in Neurochemistry. It offers graduates in science and medicine training in basic and applied neurochemistry. The Course consists of lectures, seminars and laboratory work and, in the second and third terms, research on a neurochemical topic.

Applicants should have a First or Second Class Honours degree in Biochemistry or a cognate subject, or be medically qualified.

Applicants for the Academic Year October 1985 - July 1986 should be addressed to the Secretary, Course in Neurochemistry, Department of Biochemistry, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, England.

(6805)C

EUCHEM Conference on Stereochemistry

The 22nd EUCHEM Conference on Stereochemistry, covering a wide range of topics in chemistry with emphasis on its inderdisciplinary character in natural sciences, will be held on the Burgenstock near Lucerne, Switzerland, from April 27 - May 3, 1986. The number of participants will be limited. Inquiries and applications (no special forms are required) should be addressed before January 10, 1986, to the President:

Prof. E. Winterfeldt
Institut für Organische Chemie
Universität Hannover
Schneiderberg 1 B
3000 Hannover 1
Germany

(W1931)C

The New York Academy of Sciences Conference on

Metabolic Regulation: APPLICATION OF RECOMBINANT DNA TECHNIQUES

6 November to 8 November 1985

The Barbizon-Plaza Hotel New York City

This symposium is intended to facilitate exchanges of ideas and information between scientists who study (1) regulation of the expression of genes of metabolic interest, (2) regulation of the catalytic activity of enzymes, and (3) development and use of the techniques of gene transfer, site-specific mutation and expression of cloned genes in heterologous cells.

Invited speakers include: P.P. Cohen, P. Felig, R. Fletterick, R.E.K. Fournier, S. Gluecksohn-Waelsch, J.L. Goldstein, A.G. Goodridge, M. Gottesman, D.K. Granner, R.W. Hanson, R.A. Jungmann, R.J. MacDonald, R.C. Mulligan, S.J. Pilkis, G.M. Ringold, J.M. Rosen, M. Rosenberg, C.S. Rubin, G. Schutz, S.S. Taylor, H.C. Towle, I.M. Verma, S.J. Wakil.

There will be two contributed poster sessions. The deadline for submission of abstracts is 15 July 1985. The abstracts should include the name of the author(s), institution, and a 200-word summary of the work to be presented. Send abstracts to: Dr. Alan G. Goodridge, Department of Pharmacology, Case Western Reserve University, Cleveland, Ohio 22106.

Conference Co-chairmen: Alan G. Goodridge, Ph.D. and Richard W Hanson, Ph.D., Case Western Reserve University.

Inquiries should be addressed to: Conference Department, The New York Academy of Sciences, 2 East 63rd Street, New York, NY 10021. (NW1864)C

ADVANCED COURSE IN FLOW CYTOMETRY: ANALYSIS AND FLUORESCENCE ACTIVATED CELL SORTING

Paris, September 9–14, 1985

Sponsored by: The Cancer Research Association (ARC) – Jacques Crozemarie, President, and the "Centre Technique pour le soutien de la Recherche sur le Cancer des Laboratoires et Formations du Centre National pour la Recherche Scientifique" (C.N.R.S.)

A Course in Flow Cytometry will be offered with special emphasis on cell biology. Themes will include Multiparameter cell sorting, cell lineage studies, tumor cells characterization, gene amplification selection, cloning of genes by transfection, somatic cell genetics, hybridoma variant selection, liposome endocytosis, cell cycle analysis, Brd U and cytokinetic studies, mathematical modeling of the cell cycle, computer system for multiparameter data analysis, cytochemistry and new fluorochromes, karyotype analysis, pumped dye lasers, emission anisotropy.

The Course will consist of lectures, laboratory demonstrations and problem solving sessions.

Course Directors: Harry Crissman (Los Alamos National Laboratories), Claude Rosenfeld (INSERM, Villejuif, France)

Organizers: L.A Herzenberg (Standford University, USA), P. Le Bouteiller (Centre d'immunologie de Marseille-Luminy, France), M. Monsigny (Centre de biophysique moléculaire, Orleans, France), J.L. Roti-Roti (Washington University of St. Louis, USA)

Lecturers will include the above, plus: B. Bagwell, S. Cram, Z. Darzienkiewicz, P. Dean, M. Goldberg, J. Gray, P. Horan, C. Julien, M. Loken, H.S. Micklem, K. Muirhead, D.R. Parks, A. Truneh.

Course tuition: $500 (5 000 FF) includes laboratory fees, manual, coffee breaks, lunches and an optional Flow Cytometry Certificate.

Send C.V. and tuition deposit $50 (500 FF) to the local Course Director (max. 50 persons).

Dr. Claude Rosenfeld,
INSERM Unite 253,
Groupe Hospitalier Paul Brousse,
16 bis avenue Paul Vaillant Couturier,
94804 Villejuif, France

Application deadline June 30 1985, priority given to early applicants. (W1919)C

Microbe 86 IUMS

XIV INTERNATIONAL CONGRESS OF MICROBIOLOGY

7th-13th September 1986, Manchester, England.

To be held under the auspices of the International Union of Microbiological Societies.

Sponsored by the Royal Society of London, the Society for General Microbiology, the Society for Applied Bacteriology, the Society of Chemical Industry and the British Mycological Society.

FEATURING

1. More than 60 symposia encompassing the most topical aspects of bacteriology, virology and mycology with invited speakers of highest international standing in their fields.
2. An extensive supporting programme of round table discussions, oral presentations, poster sessions, workshops and satellite meetings.
3. A comprehensive and extensive Trade exhibition.
4. A full social programme.

INCLUSIVE REGISTRATION FEE ONLY £95.00

FOR YOUR COPY OF THE CONGRESS BROCHURE PHOTOCOPY THIS FORM AND SEND TO:

Mr A.F. Yates (XIV ICM) Trading Services, UMIST, P.O. Box 88, Sackville Street, MANCHESTER, M60 1QD, ENGLAND.

Please send me the full brochure of the XIV International Congress of Microbiology.

STUDENTSHIPS continued

London School of Hygiene and Tropical Medicine
(University of London)
Keppel Street, London, WC1E 7HT

MRC RESEARCH STUDENTSHIP

Applications are invited for a three year MRC studentship, tenable from 1 October 1985. The project will involve the use of biochemistry, histochemistry, and molecular biology in an investigation into oocyte formation in mosquitoes.

Applicants should have, or expect to have, a first or upper second class honours degree in a relevant biological subject. Applications should be sent with a CV and the names of two academic referees, not later than 30 June 1985, to Professor A.N. Clements, Department of Entomology, from whom further details can be obtained. (6789)F

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF PATHOLOGY
RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship in the Department of Pathology to study the carotid bodies in heart disease. The Studentship is financed by the Mersey Regional Health Authority and is tenable, year by year, to a maximum of three years. Candidates should hold or expect to obtain a First or upper Second Class Honours degree in Zoology, Life Sciences or Cell Biology. The successful applicant will be expected to register for a PhD.

Applications, together with the names of two referees, should be received as soon as possible by The Registrar, The University, PO Box 147, Liverpool, L69 3BX. Quote Ref RV/105/N. (6769)F

The University Of Oxford
MRC CELLULAR IMMUNOLOGY UNIT

A research studentship, leading to a D Phil degree will be available starting in October 1985. Basic research in immunoregulation especially with respect to the role of T cell subsets in autoimmune disease will form the topic of the thesis

Applicants should submit a CV and the name of two referees to: The Administrator, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. (6771)F

UNIVERSITY OF LEICESTER
Department of Genetics

Applications are invited for a SERC research studentship in Genetics tenable for 3 years from October 1985. The award is 'earmarked' by SERC for research in the genetic analysis of Drosophila behaviour. Applicants should have or expect to have a degree (1st class or 2/1) in a Biological subject and have an interest in molecular, genetic or evolutionary aspects of behaviour.

The Department is well equipped for research in genetics and has excellent facilities for molecular biology.

Enquiries and applications may be made to Dr C P Kyriacou, Department of Genetics, Adrian Building, University of Leicester, Leicester LE1 7RH. (6811)F

UNIVERSITY OF DURHAM
DEPARTMENT OF GEOLOGICAL SCIENCES
BP PhD STUDENTSHIP IN GEOPHYSICS

Applications are invited for a 3 year research studentship funded by BP to work on borehole-to-borehole seismic surveying techniques and applications. The studentship will be associated with a SERC grant to Dr N R Goulty and Dr R K Taylor (Dept of Engineering) for instrument development and fieldwork. Candidates should possess or expect to receive a good honours degree in Physics, Engineering or a related subject. Applications, together with the names of two academic referees should be sent as soon as possible to Dr N R Goulty, Department of Geological Sciences, South Road, Durham DH1 3LE. (6820)F

Trent Polytechnic
DEPARTMENT OF LIFE SCIENCES
SERC STUDENTSHIP

Applications are invited for the above positions from candidates who hold or expect to obtain at least a 2(i) honours degree in an appropriate discipline
Topic areas available for study are:
Elimination of drugs through liver and kidney (Ref LS/1)
Neurotransmitter pharmacology (Ref LS/2)
Calcitonin on gastric function (Ref LS/3)
Acid rain on amphibia (Ref LS/4)
Locomotion in stick insects (Ref LS/5)
Metal toxicity to fish (Ref LS/6)
Please quote the reference number of projects which are of interest in any correspondence.
Further details and forms of application are available from the Staff Officer, Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Closing date 5 July 1985. (6765)F

THE UNIVERSITY OF SHEFFIELD
AMORPHOUS AND CRYSTALLINE QUANTUM WELL SEMICONDUCTORS
SERC PhD STUDENTSHIP IN THE DEPARTMENT OF PHYSICS

Applications are invited from graduates with a class I or II/1. Honours degree in Physics, Materials Science or Electronic Engineering for an SERC Information Technology award, to study luminescence in extremely thin layer structures of amorphous silicon which show quantum size effects. Comparative studies on GaAs superlattices will be included. The successful candidate will join an established group in the field of amorphous semiconductors especially interested in the study of photo- and electro-luminescence, using lasers and related opto-electronic techniques We are chiefly interested in recombination mechanisms and photo induced defects. This work is being extended to include quantum size effects in both amorphous silicon and crystalling III-V semiconductors. The group collaborates actively with a number of workers in the device field. The project will involve a wide range of solid state techniques with emphasis on the physics of these materials. Tenable from 1 October 1985. Applications with the names of two referees should be sent to Professor I G Austin, Department of Physics, the University, Sheffield S10 2TN by 27 June 1985 Quote ref: R268/G (6807)F

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES
MRC STUDENTSHIP
October 1985

Applications are invited for a studen ship, leading to the degree of PhI to study proliferation and mo phogenesis in skin and skin appei dages with particular reference t the role of dermal papilla cells i hair growth control mechanism: Applicants should possess or expe to obtain a First or Upper Secon Class Honours Degree in an ap propriate discipline and have an i terest in ce biology/biochemistry/development biology.

Applications, including a CV ar the names of two referees, and info mal enquiries should be directed to I C Jahoda, Department of Biologic Sciences, The University of Dunde Dundee DD1 4HN. (0382 23181, E 4264). (6783)F

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF MEDICINE
RESEARCH STUDENTSHI

Applications are invited fro candidates who have or expect to g a good honours degree in Bi chemistry, Pharmacology or related discipline for studentshi funded for 3 years, which should le to a PhD. The field of study would concerned with blood platel behaviour and its relevance vascular disease.

CV's should be sent to Dr Heptinstall at the Department Medicine, University Hospita Queen's Medical Centre, Nottin ham, NG7 2UH. (6777)F

APPOINTMENTS WANTED
advertise your qualities and qual cations through the most influenti science weekly in the world at special reduced cost of $8 per lin (Personal Box Numbers $10.00). Advertisements must be pre-paid a sent to: Nature Classified (App Wtd), 65 Bleecker Street, New Yor NY 10012. *(890)B*

MARINE ECOLOGIST/FISHERI SCIENTIST Five years post-doctor training. Expertise in invertebra ecological energetics and appli fisheries population dynamics. Exte sive experience in coral reef a macrointertidal community ecolog Agressive publication record. Seeki research or academic post. Locati open. Everything rolled into 1

Pharmacia's FRAC-100 fraction collector

Do you need a simple inexpensive collector or the most advanced programmable fraction collector – get both with the FRAC-100.

Do you need fast tube changes and microliter collection volumes or is it 20 ml fractions from a 2 liter column? The FRAC-100 does both.

Do you need data handling and integration capabilities or do you want to choose from eight different collection modes and six fractionation parameters? The FRAC-100 does both.

Your everything solution in fraction collection is from Pharmacia.

Contact us today.

Say goodbye to soft gels

Trisacryl separates better and faster

The built-in magic of matrix engineering gives you form, porosity, strength and hydrophilic behaviour. Just pure chemistry. Hard. Inert. Synthetic. The ultimate support — Trisacryl®. Whether for Affinity, Ion Exchange or Gel Filtration, Trisacryl is engineered to give you better results — guaranteed!

Get the facts in our new catalogue and give yourself a whole new scenario of problem-free chromatography.

Trisacryl is developed and manufactured by **IBF**

THE CELL ATTACHMENT/ SPREADING FACTOR FIBRONECTIN

(BOVINE/ PORCINE)

1. Binds to cell culture surfaces.
2. Increases plating efficiency of fastidious cells.
3. Increases cloning efficiency.
4. Competitively priced at £9 per mg.

Free samples of 1mg available.
For gram plus quantities price on application.

Reader Service No.167

THE ALTERNATIVE FACTOR PROTEIN A

1. Produced from a secreting strain of S. aureus by continuous fermentation.
2. Single band SDS Page.
3. Bound to *Sepharose CL 4B at 2.5 mg/ml.
4. Binding IgG better than 23 mg/ml.
5. Competitively priced — 5ml £87.50.

We can also offer Unbound Protein A at a very attractive price.

Basic Tool of the Biotechnologist's Art: S&S Nitrocellulose

Research in hybridization and recombinant DNA technology has already yielded practical results in diagnostics, pharmaceuticals, and in the chemical and food industries. S&S products are now being used in key research techniques to develop new microbes that have advanced the applied field of fermentation biotechnology. For example, S&S BA85 nitrocellulose is widely used to screen bacterial lawns for specific DNA—containing colonies (shown left).

Typically, S&S products have helped establish the applications of DNA/RNA hybridization technology. For example—screening for genetic diseases such as sickle cell anemia has become a faster, surer procedure. Or, an improved identification technique is now under development for detecting the toxins produced by disease-causing bacteria.

S&S products helped develop the microbes used by pharmaceutical companies to make interferon, insulin and human growth hormone. And, the use of genetically altered microbes in the production of alcohol for fuel is now being explored.

To learn more about S&S products for genetics research, request Bulletin #301—"Products for Nucleic Acid and Protein Research."

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product – not your experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

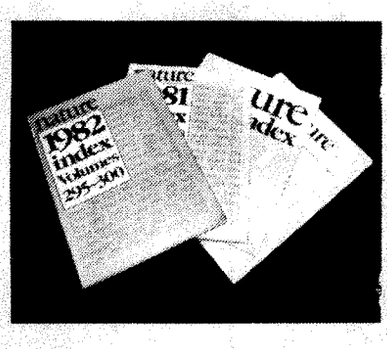
THE LANGMUIR-BLODGETT INSTRUMENT

If advanced molecular electronics is your field of interest, this is the Langmuir-Blodgett instrument for you. KSV offers state of the art thin film technology of tomorrow... today. The new KSV 2200 LB monolayer laboratory achieves the performance and reliability demanded by the fabrication of the most sophisticated LB-films.

The Automatic Film Collector system was developed to allow unsupervised deposition of ordered layers of LB-films, while consistent quality is guaranteed by the microprocessor-controlled Dynamic Film Control system.



The requisite ultra-clean atmosphere is created by the rugged laminar flow enclosure.

To make things even better, you have direct access to the KSV 2200 LB system from your personal computer through a standard RS-232C serial interface. Convenient and rapid data acquisition and processing with KSV software means flexibility and fast analysis of results – with the swiftness and accuracy you have only dreamed about. You can concentrate on the information, not the instrumentation.

Discover the state of the art thin film technology with KSV 2200 LB – the leader in Langmuir-Blodgett films.

NATURE CLASSIFIED

Professional appointments — Research posts — Studentships — Fellowships — Conferences — Courses — Seminars — Symposia: Back Pages

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

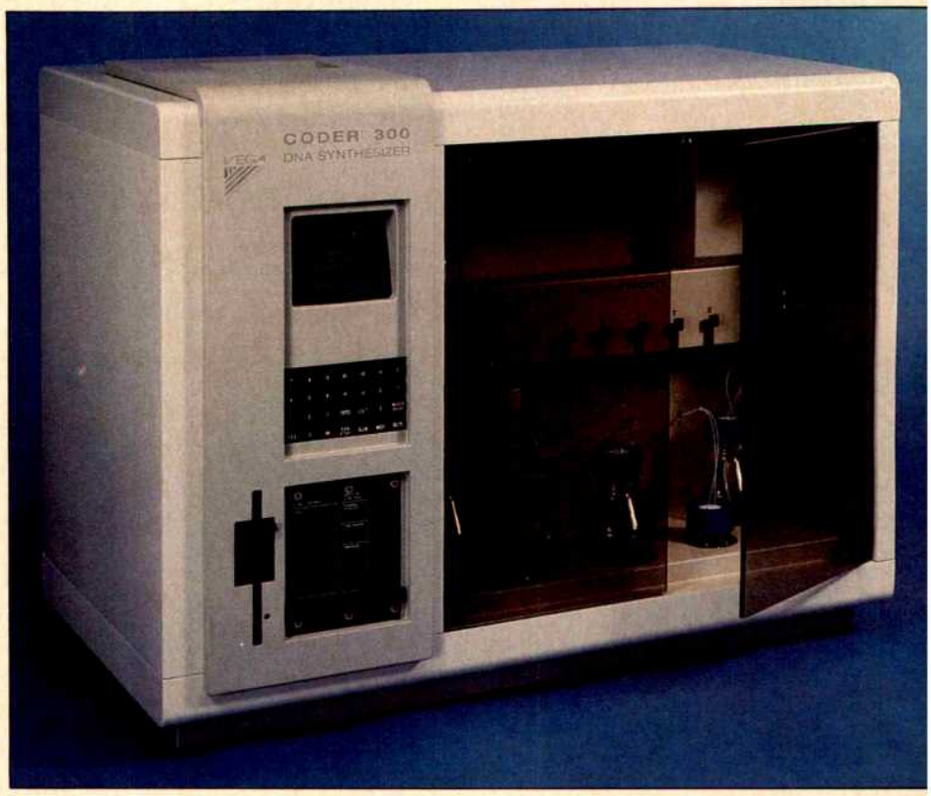
Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington). Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on seperate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.



Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

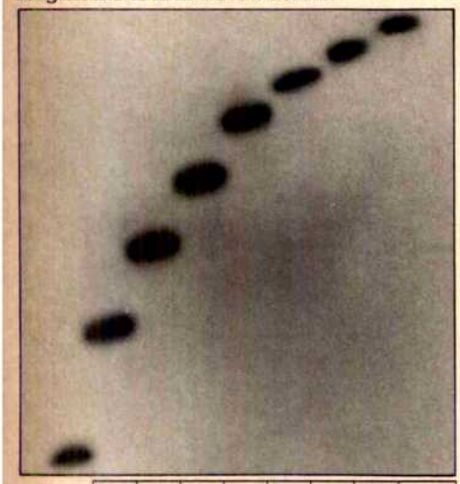
Vega Coder™ 300:



The world's most advanced computer-automated system for rapid, efficient, and reliable synthesis of DNA.

Better Performance

The Vega Coder 300 chemistry protocol utilizes β-cyanoethyl phosphoramidites, a new starting material. The β-cyanoethyl amidites offer several improvements over the older methoxy amidite compounds, including faster and more efficient coupling reactions that yield cleaner, easier to purify compounds, enhanced stability in solution, and a one-step cleavage/deprotection reaction that eliminates the need for highly toxic, offensive thiophenol.

The superior capability of the β-cyanoethyl phosphoramidites for synthesizing and improving the synthetic yield of long DNA fragments is illustrated below.

Oligomer Size	15	25	35	48	63	75	82	90*
Average DMT	98.5	98.3	98.1	98.4	98.0	97.0	98.0	97.0
Crude O.D.	170	271	216	258	368	315	412	462
Pure O.D.	71	101	45	63	33	19	5	14

*Normalized to 1 micromole

Autoradiogram, coupling efficiencies, crude and pure O.D.s of eight gel-purified oligomers of varying lengths.

Better Reliability

Vega has engineered the Coder 300 with a reliable, precise, fluid system, so accurate it can reproducibly deliver microliter quantities of reagent to the reaction column. Easy-to-use, menu-driven software facilitates fast start-up and operation of the system. The instrument also features random access of nucleotide reservoirs and premix capability for mixed-base additions eliminating the need for additional nucleotide reservoirs, a fluidized bed agitation system for optimum reaction kinetics, an additional nucleotide reservoir port for base analog additions, automatic purging and charging of reagent lines, advanced "auto diagnostics" to monitor fluid delivery, a built-in printer, computer and CRT, auto-restart capability, a snap-on reagent manifold, an output pulse for fraction collector advance, optional multi-column configuration, and more.

A Better System

The Coder 300 is a complete, integrated system of instrumentation, software, chemicals, and support services providing unsurpassed performance in DNA

synthesis. Our full line of conveniently pre-packaged high-purity reagents ensures results of only the highest quality. Technical support includes free instrument training, a comprehensive owner's manual, a one-year warranty covering parts, labor and travel, a factory-trained field service force, and optional extended service contracts.

For better DNA synthesis contact: **Vega Biotechnologies** at 800-528-4882.

You Work With Many Cell Types. So Does Opti-MEM™ I.

Introducing the First Multi-use Reduced Serum Medium.

Only Opti-MEM™ I supports optimal growth with reduced fetal bovine serum for a wide variety of mammalian cells. Most cells routinely cultured in serum-supplemented medium may be directly transferred into Opti-MEM™ I with a minimum of 50% reduction in serum. In addition to its versatility, many other unique features make Opti-MEM™ I the optimal choice for most cell culture needs.

High performance. Opti-MEM™ I actually *outperforms ordinary serum-supplemented media* in many applications.

Stringent testing. Opti-MEM™ I is performance-tested for cloning efficiency and growth promotion using various mammalian cell types, including murine myelomas, hybridomas and adherent cultures. In addition, Opti-MEM™ I is tested for pH, osmolality, endotoxin level and bacterial/fungal sterility.

Stability. Opti-MEM™ I has a shelf life of six months from date of manufacture.

Ease of preparation. Opti-MEM™ I is ready for use in only three steps: add 2-mercaptoethanol (included); mix thoroughly; and add fetal bovine serum.

Economy. Opti-MEM™ I not only decreases the amount of costly serum needed, it also is less expensive than most other reduced serum media.

For more information about Opti-MEM™ I, including performance data for a variety of cells, ask for our free technical brochure.

GIBCO Opti-MEM™ I, the reduced serum medium that works the way you do.

Opti-MEM™ I was developed by Hybridoma Sciences, Inc., Atlanta, Georgia.
For *in vitro* diagnostic use.

New Express-Blot™ System

...Background-free screening of λgt 11 libraries.

A

Express Blot —Lysate treated primary antibody for fast, background-free detection of expressed sequences.

B

Blot using primary antibody not treated with lysate.

Plaque lift assays using the Bio-Rad Express Blot assay kit. Disk A shows the result of the Express-Blot assay in which detection of rare sequences has been optimized by treatment of the primary antibody with *E. coli* lysate to neutralize cross-reactive antibodies. Disk B shows the result of the same experiment performed with untreated primary antibody. Both disks were prepared identically and contain approximately 10^4 plaques of which 1% have the gene for human albumin inserted. A commercial source of rabbit antiserum to human albumin was used to probe for expressed protein. The phage vector (λgt 11), host strain (*E. coli* Y 1090), and human albumin clone were provided by Dr. John S. O'Brien, Department of Neurosciences, University of California, San Diego, School of Medicine, La Jolla, California.

Bio-Rad's Express-Blot kit is the first non-isotopic system specifically designed to detect expressed products of rare sequences, even with crude primary antisera. The kit includes the adsorbent required to remove anti-*E. coli* antibodies, which are present in most animal sera, and which can generate false positive signals.

Our goat anti-rabbit horseradish peroxidase conjugated second antibody is affinity purified and free of crossreacting antibodies. So you detect only the clone of interest, not false positives (see figures).

The Express-Blot kit is a comprehensive, balanced package containing the high-quality components and protocol required for the complete plaque lift detection procedure. It is qualified specifically for λgt11 plaque lifts and colony lifts. For more information request bulletin 1193.

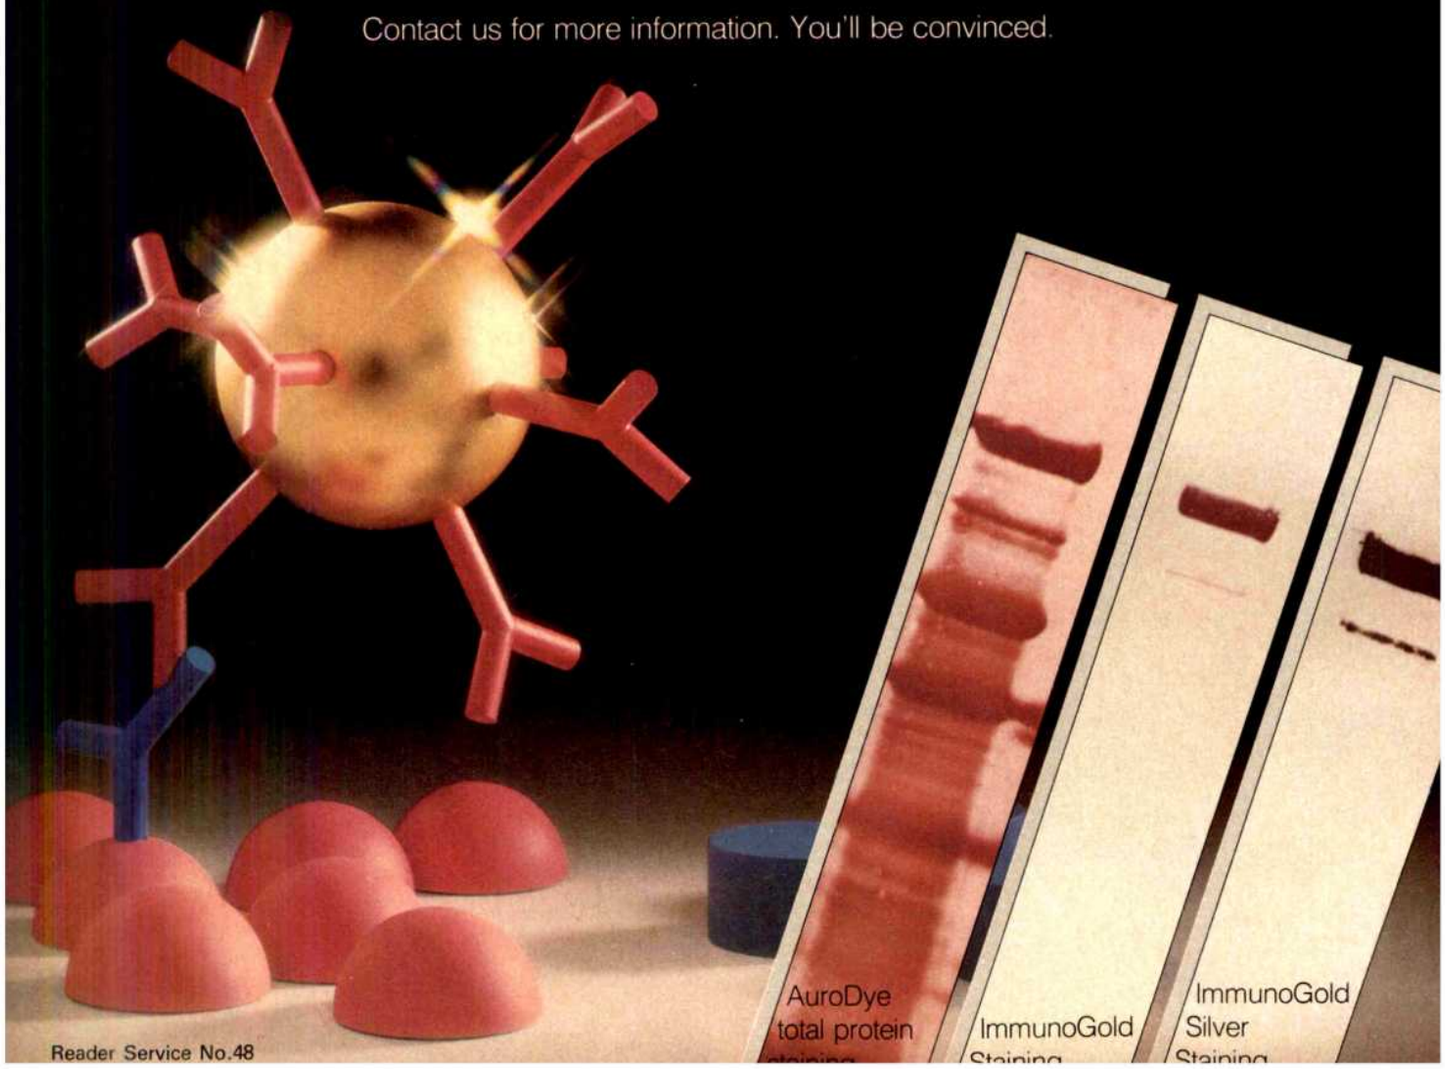
BL grade ImmunoGold

THE "AVANT-GARDE" IN ANTIGEN DETECTION ON BLOTTING MEMBRANES



ImmunoGold (Silver) Staining offers more than just one advantage over the traditional techniques:

It is **simple**. ImmunoGold probes stain the antigen sites red without any further development being required.

It is **safe**. Since it is a non-isotopic and non-enzymatic technique, there are no problems with radiation, short shelf-life or carcinogenic substrates.

It is **sensitive**. Our optional Silver Enhancement reagent turns the red signal into an intense black one, revealing sub-nanogram amounts of antigen.

Contact us for more information. You'll be convinced.

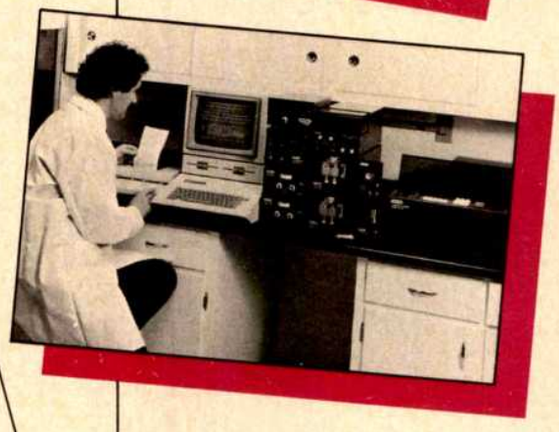
Protein separations in seconds.



Bio-Rad's new Protein Microanalyzer™ system separates protein mixtures in seconds with resolution superior to that achieved by conventional HPLC. Some of the outstanding features:

- **New technology.** Novel technology provides the basis for the rapid kinetics of the Protein Microanalyzer system.
- **Recovery.** High and reproducible recovery of samples in the μg range allows consistent quantitation.
- **Complete quantitation.** Simultaneous integration provides a run time absorbance tracing and a peak-by-peak quantitation report seconds after the run is completed.

Optional equipment allows automatic sampling of up to 48 refrigerated samples and data storage for later reintegration.

For fast separations of small amounts of protein without sacrifice of resolution, nothing equals the Protein Microanalyzer system! For more information, call us toll-free 800-4-BIORAD.

Schwarz/Mann Biotech Announces:

ACRYLAMIDE, *Ultra Pure*
Electrophoresis Grade

Our new Ultra Pure Acrylamide for electrophoresis is prepared by a recently developed three-fold recrystallization process. This new Acrylamide produces crystal clear solutions and transparent gels. The Acrylamide's performance has been checked in functional tests such as electrophoresis in Laemmli SDS PAGE gels.

Specifications:

Formula: CH_2:CH.CO.NH_2
Molecular Weight: 71.08
Purity: >99.9%
$E^{1\%}_{1cm}$ (290nm): <0.10
Acrylic Acid: <0.001%
Insoluble matters (in H_2O): <0.001%

Our **NEW** Biotech Catalog is now available. Request your free copy today.

ICN

Arms control.

λgt 11 Arms

Expression Cloning. The λgt 11 Cloning Vector has been digested with EcoRI and dephosphorylated. It accepts 0 to 7 Kilobase EcoRI inserts.

Kits contain strains Y1088, Y1089, Y1090 and a test insert. Efficiencies are greater than 10^7 recombinants per microgram of λgt 11 Arms using Gigapack™ packaging extract.

λgt 10 Arms

Genetic Selection. The λgt 10 Cloning Vector is suited for the cloning of EcoRI ligatable DNA fragments that range between 0 and 7 kilobases. Kits contain strains C600 and C600 Hfl+ and a test insert. Efficiencies are greater than 10^7 recombinants per microgram of λgt 10 Arms using Gigapack.

EMBL3 Arms

Large Insert, Genetic Selection. The EMBL3 Cloning Vector is one of the most versatile and efficient lambda-based vectors available today. Its advantages include the ability to accept BAM HI ligatable inserts (i.e. Mbo I, Sau 3A, Bgl II or BAM HI inserts up to 22kb in length), strains Q358, Q359 and a test insert are provided. Efficiencies range between $2X10^6$ and $8X10^6$ recombinants per microgram of EMBL3 Arms using Gigapack packaging extract.

λgt 11, λgt 10 and EMBL3 Cloning Vectors save valuable time and have been expressly processed to be extraordinarily effective, reliable and inexpensive. Simplicity in protocol make Vector Cloning Systems products a convenience to work with.

Reader Service No.19

nature

IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL SAN FRANCISCO, CALIFORNIA

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homoeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.
Full 3-day registration fee: $375.00
Pay only $325.00 if you register before July 31.

LOCATION

The Sheraton-Palace Hotel located at 639 Market Street is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: $95. Doubles: $105 and $115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

YOUR REGISTRATION FEE COULD BE TAX DEDUCTIBLE

CONFERENCE DINNER
Our gala Conference dinner will be held Tuesday, October 8, in the historic, glass-domed Garden Court. To insure seating, please include your dinner ticket requirements and payment of $29.50 per person with your registration.

EXHIBITS
A major exhibition of scientific products and services will be held in conjunction with the Conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

SYSTEMS

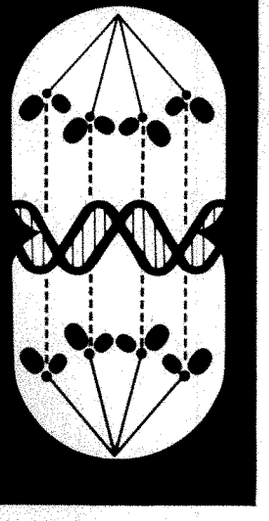
Speakers	*Topics*
F. Bloom (Research Institute of Scripps Clinic)	Vertebrate neural systems
J. Gerhart (U. of California at Berkeley)	Early development—Xenopus
C. Nüsslein-Volhard (Tübingen)	Early development—*Drosophila*
C. Goodman (Stanford)	Development of invertebrate neural systems
H.R. Horvitz (MIT)	Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers	*Topics*
M. Davis (Stanford)	T-cell receptors
U. Storb (U. of Washington at Seattle)	B cells
J.M. Bishop (U. of California at San Francisco)	Oncogenes
M. Ptashne (Harvard)	Regulatory proteins
I. Herskowitz (U. of California at San Francisco)	Yeast development
E. Jaworski Monsanto	Plant transformation

DAY 3: WEDNESDAY, OCTOBER 9



GENES

Speakers	*Topics*
R. Palmiter (U. of Washington at Seattle)	Transgenic mice
D. Hogness (Stanford)	*Drosophila* homoeotic genes
W. McGinnis (Yale)	Mammalian homoeotic genes
T. Friedmann (U. of California at San Diego	Human therapy

*Additional speakers will also appear on the program.

NAT

SAVE $50 IF YOU REGISTER BEFORE JULY 31!

A New 1985 Research Products Catalog from

Enzo Biochem

the source for *Bio-Probe*™ labeling and signal generating systems

New Approaches to:
- non-radioactive labeling and detection of DNA, RNA, Proteins and Immunological Products

Designed for
- Molecular Biologists
- Clinical Researchers
- Immunologists

Novel Applications for:
- Southerns
- Dot blots
- Westerns
- Colony hybridization
- *in situ* hybridization
- ELISAs

Featuring—*Bio-Probe*™ labeling and detection systems
- Biotinylated nucleotides and antibodies
- *Patho-Gene*™ Identification Kits—DNA based identification of pathogens

Exclusive *Detek*™ signal generating systems
- Stabile preformed streptavidin-enzyme complexes designed for optimal sensitivity

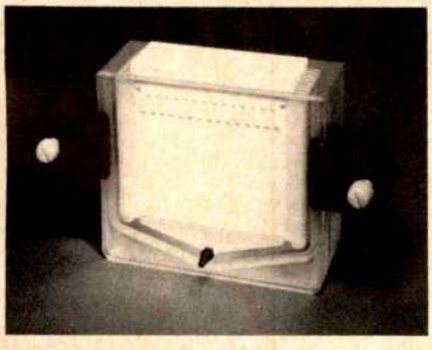
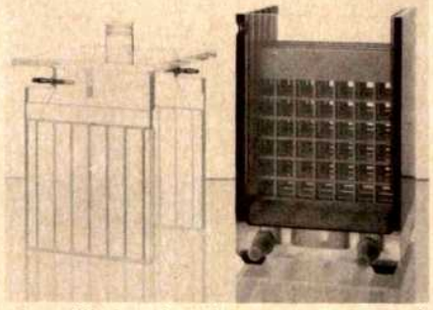
NEW PRODUCT NEWS FROM HOEFER

Hoefer has expanded the Mighty Small line



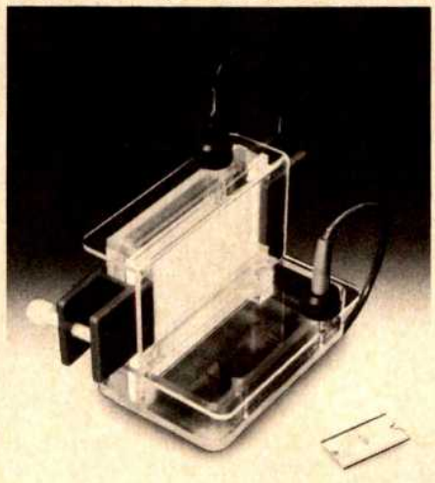
Hoefer's Mighty Small I has become the laboratory standard for doing electrophoresis in the small gel format. Now Hoefer is introducing Mighty Small II, and to complete the system, Mighty Small Transphor, Casting Stand, and Power Supplies.

• **Mighty Small II** is Cool and Fast: It can run two mini-gels, 8 x 10 cm, in 45 minutes. Two mini-gels are produced in two gel sandwiches, held back to back, in a



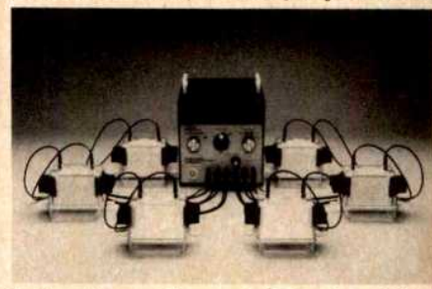
double-sided pod. The pod consists of two discretely separate upper buffer chambers and a serpentine coolant chamber between. *Cooling is the key feature of the Mighty Small design.* The back plate of each gel sandwich is in contact with the upper buffer and is made of sturdy alumina. Alumina is an excellent heat conductor, 40 times faster than a comparable thickness of glass. It rapidly conducts joule heat away from the gel sandwich into the buffer. A serpentine coolant chamber, permanently sealed between the two buffer chambers, assures further heat dissipation. This excellent cooling system means you can get flat, side by side sample lanes with no smile in 45 minutes.
Reader Service No. 51

• **The Mighty Small Multiple Gel Caster** enables you to cast 10 gels at a time, 8 x 10 cm, gradient or native. You can pour batches of gels ahead of time, probably a week's supply.
Reader Service No. 52



• **The Mighty Small Transphor** can transfer proteins from four small gels (up to 9 x 10 cm) at once, to either nylon membranes or nitrocellulose, *in as little as 30 minutes.* It comes complete with four

glass-filled polycarbonate cassettes. A serpentine cooling channel milled into the base and covered with alumina assures *excellent cooling.* Under standard transfer conditions the temperature variation will be less than 5°C. Platinum wire, 155 cm of it, strung in 14 opposing strands 1½ cm apart establishes a *uniform electrical field.* Because of its small size, it is possible to use a standard electrophoresis power supply—we recommend the Hoefer PS 500X. Mighty Small Transphor requires only a small amount of buffer, about one liter, another important cost-saving factor.
Reader Service No. 53



• If you want to run small gels, 100 mm wide x 80 mm high, the **Mighty Small I** does the job fast and right. You can run a 10% gel at 200 constant volts in only 42 minutes. The gel sandwich is the core of the design. Its alumina back interfaces with the buffer pod to insure even heat distribution across the gel surface. The result: flat,

side-by-side bands.
Reader Service No. 54

• Hoefer introduces **a new line of transfer membranes** for all blotting techniques: a pure grade of nitrocellulose to insure faithful replicas and minimal background staining, and high binding capacity Nylon 66 membranes. You have a wide choice of shapes and pore sizes.
Reader Service No. 55

• **The PS 250 power supply** is a workhorse for the electrophoresis lab. It can produce 0-250V; 0-2.5A, adjustable in

both voltage and current. It has two digital panel meters and a 7 hour timer. You can run six Mighty Small II units at one time and monitor each separately. For transfer work the PS 250 provides ample current for several small or large transfer units. *We recommend running transfers in constant current to eliminate overheating.*
Reader Service No. 56

• **The PS 500X** is the standard power supply for small gel electrophoresis. It can produce 0-500V, 0-400mA; adjustable in voltage and current; automatic crossover from current to voltage. You can run two Mighty Small II units at one time or two Mighty Small Transphor units.

The PS 500X is portable (only 8 lbs.) and compact (4" x 8" x 12").

Low Endotoxin:

Endotoxins (LPS) can cause a multitude of undesirable effects in cell cultures. Some of which are: the binding of membrane receptors, alteration of membrane permeability, and release of lysosomal enzymes.

HyClone Laboratories was the first supplier to produce sera with ultra low levels of endotoxin. In fact, every lot we produce has endotoxin levels of less than 1 ng/ml. Contact us for additional information.

HyClone defined sera are available in: fetal bovine, calf bovine, and equine.

HyClone Laboratories
1725 South State Hwy 89-91
Logan, Utah 84321

For free 40 ml samples please call us toll free 1-800-HyClone (492-5663)

Intermediate Filament Monoclonals

Differentiate cell types for more accurate tumor characterization.

Intermediate filaments: protein specific, immunologically distinguishable components of the cytoskeletal structure of major cell types.[1] They are found in virtually all nucleated cells and retain their specific expression even during malignant change.

Because of this remarkable specificity, anti-intermediate filament antibodies provide a useful tool for identifying cell origins. (See chart below.)

Intermediate filament type	Expression in normal cells	Examples of corresponding tumors
vimentin	mesenchymal cells	most sarcomas, lymphomas endotheliomas
desmin	muscle cells	rhabdomyosarcomas, leiomyosarcomas
cytokeratins	epithelial cells	most carcinomas
neurofilaments	neural cells	pheochromocytomas, esthesioneuroblastoma
GFAP	astrocytes	astrocytomas

Examples of *in vivo* normal cells and tumors recognized by intermediate filament antibodies.

Labsystems' quality control assures our monoclonals only react with their corresponding intermediate filament proteins.

These monoclonals can be used with either immunofluorescent or enzymatic techniques. . . with frozen or paraffin-embedded tissue samples.

For research use only. Not for diagnostic use.

Special offer: set of forty 35mm Intermediate Filament Reference Slides plus selected journal reprints.

For further information, contact your nearest Labsystems office.

NEW ANTIBODIES FROM TRITON BIOSCIENCES

Affinity-Purified Antibodies to Oncogene Proteins and Transforming Growth Factors.

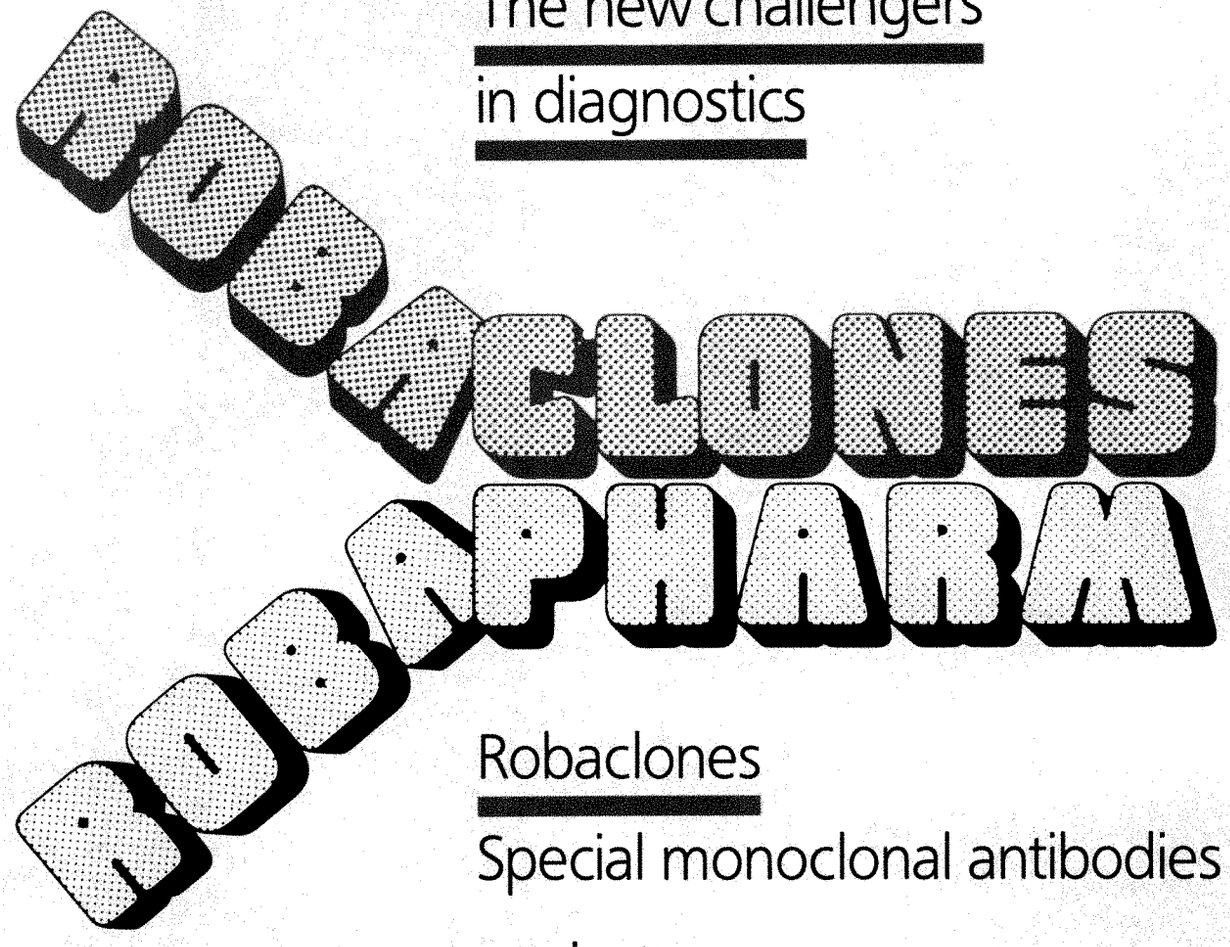
To facilitate studies in the field of oncogene research and transforming growth factors, Triton Biosciences Inc. is now offering:

- ☐ Ras^{Ha} p21 AFFI PURE™ ANTIBODY
- ☐ $Ras^{Ki/Ha}$ p21 AFFI PURE™ ANTIBODY
- ☐ Fes p85 AFFI PURE™ ANTIBODY
- ☐ αTGF AFFI PURE™ ANTIBODY

Each antibody is generated against a synthetic peptide corresponding to an amino acid sequence in the native protein. These antibodies are purified by affinity chromatography, thus reducing nonspecific reactions for clearer, faster results. Western blot and immunoprecipitation analyses are used to verify their reactivity and specificity.

Applications include: providing semi-quantitative data on oncogene and α TGF expression; localizing oncogene proteins and α TGF in cells using immunofluorescence; purifying antigens by antibody affinity chromatography; and characterizing structure/function relationships.

Triton Biosciences Inc., a wholly-owned subsidiary of Shell Oil Company, is dedicated to developing products for the human health care field, with special emphasis on cancer.



Our product development program is aggressively committed to providing a continuing source of biological reagents of the highest quality.

For additional information, contact Triton Biosciences Inc., 6900 Fannin, Dept. 270, Houston, Texas 77030. Tel. (713) 796-1227.

The new challengers in diagnostics

Robaclones
Special monoclonal antibodies
against
Endothelial cells
Smooth muscle cells
Macrophages

Robapharm has a 50 years tradition in biological research. The company today is highly active in biotechnology and provides scientists with rare monoclonal antibodies throughout the world.

These antibodies represent new tools for research on the vascular endothelium and on mononuclear phagocytes and shall be useful in diagnosis of endothelial cell tumors, pathological changes of the vessel wall (atherosclerosis) and various inflammatory cell infiltrates.

Waters ACCELL™ media. Protein isolation complete.

Conventional gel. Still on the shelf.

© Millipore 1985

Now get LC isolation of your protein in minutes—not hours. With Waters ACCELL ion exchange media.

ACCELL packs quicker, easier and allows faster flow rates—to minimize time spent on protein separations. A patented copolymerization process exploits the properties of a rigid separation media while giving excellent recovery of biological activity. Because it's not subject to the shrinking and swelling typical of gels, ACCELL provides better reproducibility and resolution previously unattainable by conventional techniques. Its rigid structure permits linear scale-up at all flow rates and pressures—from analytical to prep to process—using the same methods and the same chemistry.

Try Waters ACCELL media in your lab at no cost. Simply fill out and mail the attached coupon, and we'll send you a free trial kit which includes all the technical specifications, protocols, and materials you need to evaluate ACCELL on your protein. Or write to Millipore, Waters Chromatography Division, Dept. PM, 34 Maple Street, Milford, MA 01757.

FREE trial offer.

CON"ENIENT·INFOR.A.TI"E·TI.ELY·PRO"OCA.TI"E

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1. You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2. You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3. You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4. You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

Retreat from particle physics?

The Kendrew committee has given the expected opinion on whether Britain should pull out of high-energy physics. But was it asked the right question?

THE Kendrew committee has had a thankless task in deciding whether Britain could continue to afford high-energy physics. Its report now published (see p 619) faithfully reflects the difficulty of reaching a clear decision on such a complicated issue. The presenting symptom of the trouble that has arisen is that British spending on high-energy physics, taken entirely from the budget of the Science and Engineering Research Council (SERC), although much reduced in the past decade, is still (at £55 million) an uncomfortably large fraction of the total (£288 million for SERC in the present financial year). The consequences for the general support of science in Britain have been all too clear in the past few years. Good projects even in basic physics have languished for lack of funds and even, latterly, because those best qualified to execute them have been persuaded by the general climate that they had best try their luck elsewhere. Yet, curiously, it remains a fact that British spending on high-energy physics is not entirely out of line with what is spent by the other members of the European Organisation for Nuclear Research (CERN). As a fraction of gross national product, British spending on high-energy physics is less than that of France, Italy and West Germany but greater than that of Austria, the Netherlands, Norway and Greece. So why is it that Britain, for the time being at least, is the only member squealing about the cost?

There are some extenuating circumstances, of which the chief is the curious way in which the British government stolidly refuses to guarantee the costs of international collaborations against the effects of currency fluctuations. Occasionally, there may be special concessions from the Treasury, but more frequently there are not. The result is that research councils locked into international agreements for collaboration that have the force of international treaties must raid their provisions for domestic spending whenever sterling moves against them. The Kendrew committee has rightly asked that the British government should follow a more generous policy towards the research councils' difficulties in this regard. Indeed, it could well have made the point less temperately. For how can the government expect the research councils to plan carefully for the future, while following the rule that funds cannot be held over from one year to the next, when they can never know when it will be necessary to scrape the barrel for an unbudgeted few million pounds or so?

Structure

A more serious problem is structural, and particularly concerns SERC, which differs from other research councils in that its function is exclusively to support research in universities and polytechnics, and to provide the necessary central facilities. This is the spirit in which, in more fulsome days, SERC provided not only the annual contribution to CERN but domestic high-energy physics laboratories (long since converted to other purposes) as well. The trouble with high-energy physics is that even the reduced costs of the present operations are too large a proportion of the budget to be easily digested, but this is not the only hostage to fortune that SERC has given. Who can say whether the cost of maintaining SERC's spanking new observatories, on Hawaii and at La Palma in the middle of the Atlantic, will not become some years from now the kind of embarrassment that CERN seems now?

Commitment

The truth is that SERC's total budget of £288 million (this financial year) is not freely disposable income in the true sense. Large parts of it are committed in advance, not merely for the payment of annual instalments of research grants awarded in previous years and for maintaining central facilities and their staffs, but also because SERC has been persuaded, in what seems to have been the national interest, that it should support with its own funds substantial government initiatives, for example, information technology, and at the same time increase support for engineering research at universities. The CERN subscription, however onerous, is only one of the several commitments that explain why SERC has had so little to spend on the core of scientific research. So the Kendrew committee might reasonably have argued that it might have been spared the trouble of existing if SERC, over the years, had more zealously managed its affairs for flexibility. Somewhat delphically, all that Kendrew says is that "the organization of science in Britain should be rationalized so that funds available are used more effectively". That, presumably, is what people have been attempting for decades past.

The course of action now suggested is an awkward compromise. Nothing much will be saved in the next three years or so, although there will no doubt be a flight by graduate students from high-energy physics into other fields. Since there is very little chance of the government relenting, and allowing a substantial increase of the funds available for civil science, SERC will continue to be unable to support the projects now sent away begging for at least that long. And even if the negotiations with CERN are successful (which is improbable), there will not be much extra in the kitty — perhaps £15 million a year seven years from now, a mere 5 per cent of the annual budget. In the circumstances, it would have been better that the Kendrew committee should have bitten hard on the bullet put between its teeth, should have counted the real British moral obligation to CERN as a small consideration compared with the survival of British science, and should have plumped for withdrawal at the end of 1986 (the earliest date possible). It could have added that it would have preferred to have been asked a different question, and might even have formulated some of the more intelligent questions that need answering. But that way, at least, there would have been an early prospect of relief from the present crisis.

Ructions

But would not such a course have been a recipe for ructions? Of course, Llewellyn-Smith (see p.619) is entirely right in most of what he has to say about the consequences for CERN, and for

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, it will be helpful if they will in future send **four copies of all manuscripts** offered for publication, either (as at present) to London or Washington.

the British reputation in European collaboration, of even the compromise course of action now recommended. Outright withdrawal would have caused a bigger row, but one not qualitatively very different. Moreover, such a decision would have laid the trouble squarely where it belongs, with the government whose niggardliness has brought about the crisis of the past several years. Indeed, it is entirely possible that if the British government as distinct from SERC were faced (as it may be still) with the task of engineering withdrawal from CERN, it would find the task politically unpalatable.

Whatever happens now, the Kendrew committee has demonstrated vividly that something must be done about the condition of academic research in Britain. One of its most compelling passages is the account which it has gleaned from the public grant-making bodies of the projects the research councils are unable to support for lack of funds. This is also the theme of last week's report from the Advisory Board for the Research Councils, published early so as to inform last Friday's debate in the House of Commons (see p.623). (By all accounts, Kendrew would have been similarly dealt with if only the Department of Science and Education had had an extra word-processor.) Quite why that occasion took place is still far from clear. The initiative was that of the Secretary of State for Education and Science, Sir Keith Joseph, but on this occasion the apostle of management by cash limits spent much of his time reciting the difficulties attending British academic research, the flight of people, for example. Was the debate Sir Keith's own way of acknowledging that his critics have won the day, and of recruiting their help in talking down his colleagues in the government?

However that may be, it seems not to be fully appreciated that an urgent remedy is required. Some good ideas have always been wasted because there are no funds to back them. What matters now, in Britain, is the sheer volume of talent going to waste. Even the good ideas that, with luck, find backers are often supported with such economy that their success is jeopardized. Last week's advisory board report gives several examples of projects with industrial importance which are less successful than they might be for lack of adequate support. Is it any wonder that, in these circumstances, people's spirits have evaporated? Or that those not yet entirely demoralized think first of taking their skills elsewhere?

Yearning

The simple solution is that the government should find some extra money, on a strictly short-term basis, to see that projects of outstanding quality (and their authors) should not be lost during the painful but necessarily cumbersome reorganization of the research enterprise now in prospect. An extra £100 million spread over the next three years would do an immense amount to help. If the government is afraid of distributing such a bonus among the research councils in the usual way for fear of giving them ideas above their station, it might think of distributing the money by some different mechanism. It would be by no means unreasonable or inappropriate that there should be a national competition for shares in the central fund. If the government's yearning for industrial collaboration is seriously intended, grants from such a special fund might be made contingent on matching contributions from outside. Is that modest request too much to ask?

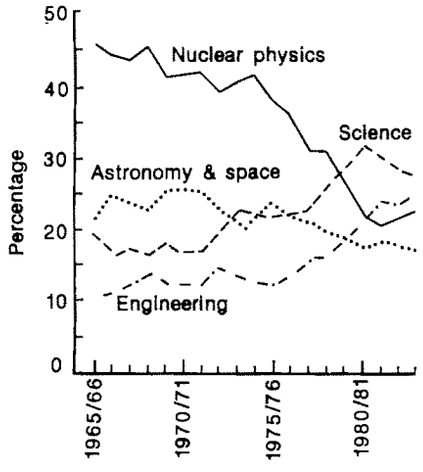
Otherwise or perhaps in any case, the research community should take what steps it can to hasten the reorganization of resources on which it has embarked, but which will work its way through the system only after several years. The University Grants Committee and the research councils have the common objective of concentrating resources for research on the institutions best qualified to make use of them, but the process will not begin until next year. Why wait that long? And why, in the interests of fairness, contemplate a long period of transition from the present indiscriminate distribution of resources to a less egalitarian system? Why not move faster, recognizing that the pursuit of fairness may be a luxury when the danger is that the quality of British research will be irreparably damaged? □

The logic of Europe

The plan to turn Europe into a true customs union by 1992 deserves a welcome.

At long last, there is a chance that Europe will become the integrated economic entity of which the founding fathers dreamed thirty-five years ago. Or, at least, the member governments (now twelve, with the accession of Spain and Portugal) will be compelled at next month's annual summit meeting at Milan to come off the fence and to make plain what kind of Europe they wish to see emerge in the remainder of this century. Ordinarily, governments struggle to avoid answering questions of such a general character. The need now to face them arises because the European Commission, the executive branch of what passes for the government of the European Communities, has produced an unexpectedly radical reply to a request last year from member governments for an outline of the steps that would have to be taken if internal customs posts were to be abolished. What the Commission says is simple. There is no reason why customs posts should not be swept away, but it will first be necessary for European governments to make more similar the domestic taxes they impose on the sale of goods.

There is the rub. Over the years, European governments have allowed the accumulation of a bewildering variety of indirect taxes on goods as different as alcoholic drinks, tobacco products and commodities considered to be luxuries, motor cars included. Then, membership of the European Communities has compelled the development of a novel system of indirect taxation, called value-added tax (VAT), which is levied at different rates on different classes of goods by the several members of the Communities. The continued existence of customs barriers within Europe is partly a consequence of this patchwork system of indirect taxation. The Commission now proposes that member governments should be constrained in their freedom to levy indirect taxes. During a transitional period, they will be expected not to allow the rates of tax to range outside prescribed limits. The Commission says that it should be possible to arrange that everything could be ready for the abolition of internal customs posts by 1992, which is asking a great deal. The immediate objection, of which much will be heard at Milan, is that the member states are not ready to relinquish such a visible sign of national sovereignty as their freedom to fix domestic taxes.



Pragmatically (which is in itself unusual but welcome), the Commission does what it can to defuse this argument by pointing out that the differences between the taxes levied on goods at the point of sale are not so great that their approximation during the next seven years will be impossible. And, in any case, the argument continues, the experience of federal systems such as the United States has shown that even substantial differences between sales taxes levied in neighbouring states do not send consumers scurrying across state lines in search of bargains in the shops. But there is an important issue that the Commission overlooks — the possibility that member states may wish to engineer substantial changes in the balance between direct and indirect taxes in their national accounts. For entirely good reasons, the government of New Zealand has already shifted the burden of taxation from income to consumption taxes (and lost the Timaru by-election at the weekend chiefly as a result). The government of Australia is planning to follow suit, while even the British government has, in previous years, talked of similar proposals. So the European Commission's proposals are more radical than they may seem. Prudent member governments will accept them — and they should — only if there is a mechanism by which general questions of taxation policy can be raised and decided on a European basis in the decades ahead. But that will imply a substantial step along the road to a federal Europe, as the objectors at Milan will be quick to say. The logic of the circumstances that have now arisen, however, is that Europe can not hope to be an integrated market of nearly 400 million people without becoming at the very least what many outsiders think it is already, an effective customs union. □

CERN

Kendrew takes knife to high-energy physics

THE technical consultant to the Kendrew committee on British involvement in high-energy physics, Dr Christopher Llewellyn-Smith, had repudiated the committee's chief conclusion (see *Nature* 29 May, p.266) within minutes of its formal publication earlier this week (*High Energy Particle Physics in the United Kingdom*). Of the recommendation that Britain should seek a reduction in its contribution to CERN, the Geneva high-energy physics laboratory, of "at least 25 per cent by 1991", Llewellyn-Smith says that the "unsubstantiated assertion" that such a reduction could be attained without detriment to CERN's position is, simply, "false".

That the Kendrew report would be contentious has always seemed probable. In the event, however, the report is a model of clarity, which should comfort both its supporters and its critics. Briefly, the conclusions are that Britain should remain a member of CERN "on the present basis" until 1989, but that it should continue beyond that time only if that can be done "at significantly lower cost". The timing is determined by the construction programme for the new electron collider LEP.

The committee notes that British scientists continue to make important contributions to high-energy physics and that the subject is at present at an exciting stage, but it also says that British spending on high-energy physics is too great a proportion of the present or "any realistic" budget of the Science and Engineering Research Council (SERC). It recommends that modest economies should be made as soon as possible; principally in the budgets of groups working on experiments at CERN, does not expect these to be substantial before the financial year 1988–89, but would expect them to increase to "at least 25 per cent"by 1991.

The committee says that the proposed reduction of the CERN budget would be an "attainable adjustment" that would "still allow the laboratory to maintain itself at a world class standard albeit at a reduced pace of development". The proposed reductions of domestic expenditure would entail "a significant decrease in the size of the experimental community" (now estimated to consist of 400 senior people and 240 graduate students), but the committee says that it should be possible to arrange for an orderly contraction while maintaining an "appropriate" British contribution to the field

The report argues that the financial circumstances of the United Kingdom which have led the committee to its conclusions "may not be unique" among CERN members, that "the overall level of expenditure on the subject is too high" and that "it would not be counter to the long-term interests of the field" if the pace of development were reduced "worldwide and not merely at CERN".

The committee acknowledges that the total budget of CERN has decreased by 20 per cent in real terms over the past decade, and that British spending on high-energy physics has declined during the same period "from what was an extraordinarily high level". It also says that there is insufficient support for first-class research proposals both in high-energy physics and in other areas

The report suggests that there is at present little room for manoeuvre within the British budget, pointing out that there would be no point in remaining a member of CERN if it were not a first-class laboratory and if domestic funds were insufficient British physicists to make full use of it. The report also says that there is a "strong moral obligation" on the United Kingdom to remain a member of CERN until LEP is finished as well as to continue development of the three particle detectors being built for use with LEP.

The Kendrew committee therefore argues that the British delegation to CERN should press for an immediate review of the financial structure of the CERN laboratory, with the objective of reducing costs after 1989. Allowing for both domestic savings and reduced expenditure at CERN, the committee calculates that it should be possible to save a total of $55 million over the next seven years, or an annual $13.8 million (at present prices) in 1992–93 and succeeding years. The Kendrew committee asks that the British government should help to avoid future difficulties by arranging that the budgets of the research councils will not be further eroded by inflation, and that the research councils should be insulated from fluctuations of exchange rates.

The committee goes on to say that even the saving likely under its proposals will not "in itself solve the financial problems of other areas of science", and that extra funds will be needed if the British research base is to meet "the challenges of the next decade".

Formally, the report is a recommendation to SERC and the Advisory Board for the Research Councils, on whom will fall responsibility for deciding what should be done. The most likely next step is that negotiations will be opened with CERN on the proposed reduction of the budget. Most probably, there will be no biting of bullets unless and until those negotiations seem about to fail. □

Informed dissent

THE dissenting opinion from Dr Christopher Llewellyn-Smith, reader in theoretical physics at the University of Oxford, is strong meat. It begins by saying that the real issue facing the whole of British science is "the erosion of our superb scientific tradition" by the inadequacy of funds. Llewellyn-Smith says that he informed the Kendrew committee of his dissenting opinion before making it public.

Among Llewellyn-Smith's objections are the following.

- **The demand that the British contribution to CERN should be reduced by 25 per cent implies a similar reduction of the total budget.**
- **Given that salary costs at CERN are roughly half of the total budget, reducing the budget by a quarter would require either a disproportionately larger cut of scientific activity or a reduction of the staff employed (which would not yield immediate savings because of the high cost of redundancy).**
- **It is inconceivable that the necessary two-thirds majority for a 25 per cent cut in the CERN budget could be found among the present membership, for which reason the committee's main conclusion "implies withdrawal . . . the committee fails to face up to this consequence."**
- **The suggestion that the proposed domestic reduction of 25 per cent could be orderly "is ludicrous"; because of the long timescale of high-energy physics experiments, the cuts would fall on those whose projects are about to be completed.**
- **As recently as 1981, SERC offered the opinion that the budget for nuclear physics should remain constant, since when high-energy physicists have made long-term commitments.**
- **The recommendations in the report would seriously damage particle physics, would damage the credibility of the United Kingdom as a collaborator in science projects and yet would make only a small contribution to the "solution of the crisis in science funding".** □

Sandia Labs

Looking to the future

Albuquerque, New Mexico

A CARTOON circulated recently at Sandia National Laboratory shows a wizard complete with pointed hat gazing intently into a crystal ball; a sign on the door in the background reveals the location to be the head office of the Future Options Group (FOG) an 8-man team of defence scientists which spends its time trying to do just that. Glenn Kuswa, manager of the FOGs (as they are known) for the past 10 months, admits that the mysterious-sounding group of futurists that he leads is a fair target for cartoonists, but he insists that the group is taken perfectly seriously by Sandia's senior management. In a national laboratory with primary responsibility for defence, future-gazing is a serious business.

FOG was formed to advise on long-term planning at Sandia only three years ago, but has already had a significant impact on both the weapons development and the basic science at Sandia. Its concern about the importance of high-speed computing, for example, led to a new laboratory division devoted to computer architectures. Sandia, in addition to carrying out contract research (mainly for the Department of Energy), is charged with anticipating future defence needs, and several of its major research efforts, such as sub-micrometre semiconductor technology, were initiated by the laboratory management

While the laboratory's primary mission is still research into nuclear weapons, the scope of this work has broadened considerably in recent years, so much so that the laboratory recently had to be reminded by Washington that biological research, at any rate, could not be considered part of its mandate. More and more projects are carried out in collaboration with commercial companies, and the number of staff has grown to match Sandia now employs more than 8,000 people, a figure that is not expected to increase further.

FOG is the creation of an informal group of laboratory managers seeking a mechanism for looking beyond the normal course of events, pondering how Sandia should anticipate the future

The group started by concentrating on strategic defence, and gave advice on the subject to the White House long before President Reagan's famous star wars speech of March 1983. Missile defences continue to take up a large part of the FOGs' time. Electrothermal guns might, according to Kuswa, be capable of accelerating projectiles to even greater velocities than the rail guns now being intensively investigated for the Strategic Defence Initiative: the physics of impacts at extremely high velocities and their implications for weapons design are one focus of the FOGs' attention.

So far, most of FOG's divinings have been delivered as briefings to Sandia's senior management, with some informal contacts with outside bodies such as the Congress's Office of Technology Assessment Kuswa thinks FOG has played an important, if little-known, role in fostering communications between different factions at Sandia, and wants to see it move towards producing more formal written reports in future.

Not surprisingly, the successful maintenance of nuclear defence is counted the group's primary objective. The issues tackled range from the particular — for example, hypervelocity guns — to the general — brainstorming and arranging training courses in global security issues such as the world's energy supply.

Kuswa has thought about how the "nuclear winter" hypothesis might affect deterrence, but FOG is not yet committed to studying the topic in earnest. By and large FOGs just think, rather than do experiments, and Kuswa thinks that the group should wait until there are more data on nuclear winter before addressing it.

FOG can see further into the future of photonics and fibre optics, which might lead to revolutionary advances in computing speeds and which Kuswa says will certainly have important implications for the way high-speed data are recorded. Such matters are crucial for the strategic balance of power, and Kuswa believes computing is important enough to warrant at least one FOG member permanently tracking it Such is the speed of progress that Sandia boasts that it has recently produced an experimental computer nicknamed the "VAX in a lunch box"

Software engineering is another topic FOG is studying; Kuswa is alert to the possibility that, despite what many see as a disappointing track record so far, artificial intelligence research could yet rock the strategic boat. In one attempt to make the future come a little sooner, Kuswa's group recently sought to apply expert systems, a spin-off of artificial intelligence research, to some of the laboratory's work. A retired employee had his expertise on the electrical wiring and connectors of nuclear warheads programmed into an expert system for the laboratory's future use. Kuswa hopes to persuade Sandia to make further use of expert systems for similar tasks in future.

A related subject is the likely availability of custom integrated circuits. Whereas circuit design is today still the province of the expert, the increasing sophistication of computer-aided equipment suggests that before too long the design and manufacture of a high-performance integrated circuit engineered for a specific task will be within the reach of most engineers. Contrary to FOG's usual approach, the group recently staged a demonstration of the production of specific integrated circuit.

Kuswa would like ultimately to establish a database of all military hardware, as a resource for studies of what the Department of Defense's shopping list is likely to look like in future (future bombing "platforms", including unmanned ones, are the subject of a current study). This, however, has proved difficult and is unlikely to be accomplished soon. In the meantime, there are plenty of other subjects to think about, and Kuswa can apparently see far enough into the future to know that FOGs are going to be in continuing demand. "We have," he says, "earned our keep."

Cell lines jump US customs

Washington

THE US Department of Agriculture (USDA) has agreed to simplify and streamline its quarantine rules for the import of cell lines. Biotechnology companies have been complaining of delays of as much as a year while tissue cultures and tissue-culture products await testing at USDA's Plum Island quarantine facility. Industry sources say they hope the new procedures will cut that time to two months.

USDA's quarantine rules apply to imports of any materials that could contain foot-and-mouth disease virus and other livestock diseases not already present in the United States. Thus cell lines prepared with bovine serum or the enzyme trypsin (which is derived from cows and pigs) come under the quarantine. The safety test involves inoculating a steer, waiting 4–6 weeks and analysing a blood sample.

During negotiations between USDA and representatives of the biotechnology industry on speeding up the process, it became clear that most of the delays were bureaucratic. Companies would, for example, be sent a bill for a test that had to be paid before testing would begin. Under the new procedures, companies will be able to establish deposit accounts with USDA so that the tests can be run as soon as products arrive at Plum Island.

The new rules will not, however, provide exemptions from the strict testing requirements that the industry had been seeking in respect of materials to be used only in clinical applications or *in vitro* diagnostics. The industry argues that so long as such materials are disposed of properly, there is virtually no chance of livestock being exposed. USDA officials say that discussions with the industry on this issue will continue.

Stephen Budiansky

Polish universities

Reforms threaten independence

POLAND'S Main Council for Science and Higher Education, the representative body of the university community which serves as an intermediary between the universities and the Minister of Science and Higher Education, stands to lose most of its powers in the planned reform of the 1982 Higher Education Act. Since the discussions on reform began last autumn, the Main Council has resolutely opposed the proposals which would effectively annul the university autonomy won during the Solidarity era. A vote taken on the proposed changes early in March showed only one member of the council in favour of the changes, with a handful of abstentions Now, a new draft of the proposed reforms, which reached us last week, threatens the status of the Main Council itself.

The 1982 Act established the Main Council as the supreme elected organ of the university community. It has seventy members, fifty from the universities and colleges under the ministry and the rest from the medical, physical training, art, drama and maritime colleges. The council has power to decide on the direction of research and the organization of studies, to set the conditions for the awarding of academic degrees and has the right of consultation with the minister on a wide range of financial and administrative matters. The original version of the reform strengthened ministerial control and disciplinary powers over the universities, bringing the "students' self-government committees" within the framework of the Party youth organizations, but the role of the council was left virtually unaltered.

With the Main Council resolutely opposed to the proposals, however, the government clearly decided to think again. Of late, the issue has no longer been in the hands of the minister of science, Dr Benon Miskiewicz, but had been handed over to the government's Committee for Social and Political Affairs, under Deputy Prime Minister Mieczyslaw Rakowski. The new draft which has emerged would impose considerable restrictions on the Main Council. First and foremost, the members of the Main Council would no longer be elected, but instead would be "appointed by the chairman of the Council of Ministers at the request of the Minister of Science and Higher Education" (Art. 18.1). "Directions of study" will now be decided not by the Main Council but by the minister (Art. 8 2) And, under the greatly revised Art. 2, the Main Council will no longer "decide at the request of the Minister" but only "give an opinion" on "possible and definite plans for the development of higher education". The same article does, indeed, leave decision-making on research within the universities and in the competence of the Main Council, but with the proviso that its decisions must be within the framework of the central economic plans. On matters affecting the terms of employment of academic staff, the minister will decide "after hearing the opinion of the Main Council" instead of, as at present, "in agreement with the Main Council".

The latest version of the reform will therefore reduce the Main Council to, at best, a powerless talking shop for the universities and, at worst, a rubber stamp for the decisions of the minister and the economic planners. During a special plenary session of the Central Committee of the Polish United Workers' Party last month, General Jaruzelski reiterated the official viewpoint, that the universities cannot any longer be allowed to be the breeding ground of political opposition, but must be more closely incorporated into the socialist structure This triggered nationwide student protests, as a result of which Rakowski and Miskiewicz found it necessary to assure university rectors that the reforms would not be made an excuse for a political purge.

Vera Rich

Electricity supply

Cross-Channel power games

FRANCE will begin pumping 1,000 MW of its cheap nuclear electric power across the English Channel into the British grid later this year, when the first stage of a new 2,000-MW undersea link is completed.

The new cables — four of them — run from Les Mandarins, south of Calais, to Folkestone. They will increase the French-British power linkage more than tenfold, from the present 160 MW transferred along a line between Dungeness and Boulogne mainly to even-out peak demand on each side of the Channel.

But the new link will open in two 1,000-MW stages And while the English utility, the Central Electricity Generating Board (CEGB) and its French partner, Electricité de France (EDF), have reached agreement on the first stage, for France to supply Britain with cheap power, the use of the second 1,000 MW is still in dispute

On its side, EDF would like CEGB to buy another 1,000 MW of "baseload" continuous power at French marginal supply prices, which EDF is quoting at attractive rates. This is not surprising, as within a few years the French electricity supply will be more than 70 per cent nuclear. Nuclear reactors are hard to turn on and off, so the responsiveness of the French network to demand fluctuations has been decreasing, despite efforts to make French pressurized water reactors more variable.

CEGB, on the other hand, in considering a second 1,000 MW from France, is said to be concerned about its agreements with the British National Coal Board (NCB), now recovering from its year-long coal strike. CEGB is by far the coal industry's biggest customer, and is contractually committed to buying large amounts of NCB's coal. CEGB cannot buy too much French power without endangering those agreements, and the British coal industry, it is claimed

Or, to put it differently, it seems that while 1,000 MW of French electricity is convenient enough to make a sharp point to the government and NCB about the value of nuclear power — and a warning that coal prices had better be kept down — 2,000 MW from France might be contractually uncomfortable.

Robert Walgate

CSIRO on the right rails?

Canberra

THE Australian Minister for Science, Mr Barry Jones announced last week the appointment of Dr N.K. (Keith) Boardman as the next chairman of the Commonwealth Scientific and Industrial Research Organisation (CSIRO). Dr Boardman, for the past eight years a member of the three-man CSIRO full-time executive and formerly chief research scientist of the CSIRO Division of Plant Industry, will take the reins for nine months in the first instance, beginning in September when the present chairman Dr J.P. (Paul) Wild retires. Mr Jones also announced the appointment of two new part-time members of the executive, Dr Adrienne Clark, a Melbourne University botanist, and Dr Kevin Foley, chairman of the Australian Industrial Research and Development Board. Like that of Dr Boardman, their appointments are for nine months pending the outcome of a series of reviews into government-sponsored science in Australia being undertaken by the Australian Science and Technology Council, in the course of which CSIRO is only the first research establishment to come under scrutiny.

The conclusion of the CSIRO review is meant to coincide with Dr Wild's retirement. A former chief research scientist of the CSIRO Division of Radiophysics and 1980 Royal Medallist of the Royal Society, Dr Wild has personally lifted the public profile of CSIRO through highly-visible and commercially-orientated work on the new aircraft landing system Interscan and, more recently, his plan to link Australia's two largest cities with the national capital Canberra using trains operating at speeds of up to 350 kilometres per hour.

Jeffrey Sellar

Arianespace

Europe's launcher cashing in

ARIANESPACE, the French-based company that sells the successful European space launcher Ariane, has tripled its turnover compared with projections made when the company was set up five years ago, according to company president Frédéric d'Allest last week. Bursting with enthusiasm, and apparently happy to challenge competitors in the United States and anywhere else, d'Allest said Arianespace has 35 satellites and FF7,000 million (£600 million) on its order books.

"There has been a very dramatic increase of activity" and "we at Arianespace are the only launch agency that can balance its accounts", d'Allest said. Arianespace was planning three launches a year and now is planning a firm six, with up to eight a year possible.

A further new launch pad, ELA 2, will be inaugurated at the Kourou launch site in French Guyana, north of Brazil, in October. At only five degrees of latitude from the Equator, compared with Cape Canaveral's 28 degrees, the site has the benefit of greater natural launch velocity (from the Earth's rotation).

At the same time, d'Allest dismisses all competition in launch vehicle manufacture. In the United States, attempts are being made to commercialize the "obsolete" Atlas Centaur and Thor Delta rockets. But there will be no significant improvement in the technology of expendable launchers in the United States, he claimed. For, d'Allest argues, no commercial company can bear the costs of launcher development while the US government is unlikely to make a substantial contribution to the development of expendables for fear of undercutting the economics of the space shuttle.

Meanwhile Ariane development goes on apace, he said The penultimate Ariane-1 should launch the Halley probe, Giotto, Ariane's first interplanetary mission, on 2 July, while the slightly bigger Ariane-3 has become the main Arianespace workhorse. Ariane-4, with strap-on liquid and solid-fuel boosters, designed for a new generation of telecommunications satellites, will be launched in mid-1986 and enter commercial service the following year.

After Ariane-4, a completely new design of Ariane will take over, a design using HM-60 cryogenic engines now under development by the French national space agency CNES. This "Ariane-5", capable of launching the bigger communications satellites being developed, will carry Arianespace from 1995 to the end of the century.

Arianespace could face some competition from Japan's H2 launcher, but H2 is too small, more comparable with Ariane-4 than Ariane-5, said d'Allest. Moreover, Japan is constrained like the United States by the northern location of its launch site.

The problem with the Soviet Union, a potential competitor, is that its launch sites are under military control and very tight security, so very little information emerges on launch technologies, communications facilities and so on, too little to make possible fruitful cooperation with a commercial client. In China, the Long March 3 rocket, at the testing stage, is similar to Ariane-1 Chinese technology will develop, but like Japan, China is hampered by a northern launch site. And the painful West German experience in the private OTRAG venture, which attempted, unsuccessfully, to use ultra-cheap technology and a Zaire launch site, showed that there was no easy route to space. d'Allest acknowledges that fibre optics may become competitive with communications satellites on certain trunk routes, but considers that there will be enough launcher business left to keep Arianespace healthy.

That leaves Arianespace, which has taken 48 per cent of the world commercial satellite market since 1981, "in the clear", given that the US space shuttle has proved expensive. The company's objective, according to marketing manager Jean-Claude Bichet, is to take one third of the market, which is to be found 40–50 per cent in the United States, 18–20 per cent in Europe, 10 per cent in the international bodies Inmarsat and Intelsat, and 20 per cent in the rest of the world. Arianespace hopes soon to be launching 8 to 12 commercial satellites a year.

Robert Walgate

Rocketing insurance

ARIANESPACE may have to wait a year before it can announce reductions in the insurance premiums for satellites launched on Ariane, even though these premiums have reached punishing levels after satellite losses on the space shuttle (see *Nature* 6 June, p.447). So said M. Charles Bigot, director-general of Arianespace, who was in London last week with his president, Frédéric d'Allest, to discuss, among other things, new insurance terms with City of London brokers.

"We had hoped to announce new terms at the Paris air show a few days ago", said Bigot, but the problem has proved more difficult than expected. "The insurance companies are treating all launchers as if they were the same kind of car", Bigot complained. But Arianespace is not going to fight dirty and use French government pressure, as it could now that most French sources of finance are nationalized. "This is a commercial question and we shouldn't mix it with politics", he said.

Robert Walgate

Exhaust emissions

No agreement in Europe

Brussels

VEHICLE emission limits announced two weeks ago by European environment commissioner Stanley Clinton-Davis are expected to receive a very cool reception from the ten environment ministers when they meet in Luxembourg on 25 June, which could yet again delay a decision to control car pollution.

Last March, environment ministers of the European Community had agreed to stagger deadlines for the introduction of new emission standards according to engine capacity, and had asked the European Commission to provide exact figures for emission limits for carbon monoxide (CO), hydrocarbons and nitrogen oxides (HC and NOX) and for nitrogen oxides on their own (see *Nature* **314**, 304; 1985). These figures, it was agreed, would achieve an environmental effect equivalent to that reached in the United States, and would allow the use of lean-burn technology in the case of the medium category of car (1.4 – 2.0 litre).

But the limits suggested last week for medium cars (30 grams per test for CO, 8 g/t for HC plus NOX and 4 g/t for NOX) seem to be unobtainable with lean-burn technology. When differences between the European and US test cycles are taken into account, the suggested limits are stricter than the standards applied in the United States and could remove 20 per cent of present large cars from the roads.

Several countries consider these new figures unrealistic and feel they do not correspond with what was agreed at the March council The United Kingdom had suggested 35 g/t for CO, 12 g/t for HC plus NOX and 6 g/t for NOX, while Italy and France, which have carried out their own tests in the meantime, maintain that 4 g/t for nitrogen oxides is not achievable except by using the catalytic converter.

Mr Clinton-Davis is determined to take a firm stand. His aim is to see NOX emissions in the Community cut by half from 3 million tonnes to 1.5 million tonnes.

But the Commission's proposals are unlikely to please those countries seeking a more flexible approach Furthermore, they will once again put West German interior minister Friedrich Zimmerman in a difficult position. At the last council, he obtained Community approval to go ahead with plans to introduce national tax incentives for clean cars, but these incentives have to be tied to clear-cut emission standards. If Community ministers cannot agree, Zimmerman will either have to rely on US standards when the incentives come into effect on 1 July or continue to hold up the project, which could further adversely affect an already depressed car market.

Anna Lubinska

British science

Commons debate cuts little ice

LITTLE blood was drawn, and no concessions won from the British government, during last Friday's debate on science in the House of Commons. But the government had agreed to the demand of Dr Jeremy Bray, the Labour Party spokesman on science, that this year's advice from the Advisory Board for the Research Councils (ABRC) should be published for the debate, it asks that the government should give the research councils £85 million extra over the next three years and wrings its hands over the rate at which younger scientists are leaving Britain.

Sir Keith Joseph, Secretary of State for Education and Science, admitted at the outset that a "significant" part of the science budget has had to be spent on activities other than research, but insisted that the government has protected the budget in gross terms. This assertion was disputed by many members of parliament (MPs) during the debate (see also *Nature* 23 May, p 271), for example by Dr John Marck, who pointed out that the Agricultural and Food Research Council (AFRC) is facing cuts of £10 million this year and £20 million next.

Sir Keith also acknowledged that the number of scientists leaving Britain to work abroad where the potential rewards are greater is a matter for concern On the other hand, he was encouraged by the increased collaboration of the research councils (which fund much of Britain's civil research) with industry in a selective and efficient way. He applauded the reduction of the research council's long-term commitments and their consequent increased flexibility and concluded that, for British science, "the way forward must be to scrutinize carefully the priorities implicit in the present balance of funding between subject areas and to consider whether some adjustments may be needed better to serve the national interest". He promised to assess ABRC's recommendations in this year's public expenditure survey, but demanded more investment in basic science from industry, particularly in engineering.

Opposition and Conservative MPs alike demanded action from the government to keep Britain in the front line of international science research. Dr Bray said that the least the government could do is to guarantee ABRC's recommended increases. His worries about the enforced drift of scientists elsewhere were epitomized by the £25 million laboratory set up by a US pharmaceutical company for Dr Leslie Iversen, formerly head of the Medical Research Council Neuropharmacology Unit at Cambridge. Dr Bray said that the work should be available to science generally and to British companies for commercial development, rather than being "pre-empted" by a US company He argued for the creation of a Minister of Science, and for an annual survey of industrial research and development

Mr Ian Lloyd (Conservative) endorsed Dr Bray's proposals but had one of his own to make as well, the setting up of an Office of Technology Assessment similar to that in the United States This independent body would serve both houses of Parliament, would be non-political and would address fundamental issues of current interest such as Mr Enoch Powell's embryo protection bill, acid rain, nuclear power and the commercial implications of biotechnology

ABRC has set up its own working party, chaired by Professor Mathias, to examine funding of research by the private sector and to consider how it is to be extended. Its findings will be published in September of this year.

Among many other suggestions as to how the government should support science was that of Mr Robert Jackson MP to find money from the defence research and development budget. In 1981, Britain spent $3,000 million on civil and $3,256 million on defence research and development. Equivalent figures for France and West Germany in the same year were $4,370 and $2,591, and $6,698 and $646, respectively. Britain could, therefore, adjust its balance of spending accordingly
